The following case is instructive in that it illustrates the difficulties so often encountered at the bedside, of understanding the true nature of an affection, of correctly interpreting a given train of clinical manifestations. The subject that shall serve us in our discussion this evening is a woman, of medium height, aged forty-nine, passed the menopause in 1889. Family history good. Had pelvic abscess in 1883. Recovered without operation. Convalescence tedious, but complete, and remained in good health until August 13, 1893, when she was taken suddenly with sharp pains in the back of the neck, the cervical muscles contracting strongly and drawing the head backward. The pain radiated downward, along the intercostal spaces, then into the stomach and abdomen, and finally settled in the ileo-cæcal region, where it became fixed, being relieved by a hypodermic of morphia.

Dr. W. B. Hoge, who attended her from the beginning, stated that on his arrival he found a temperature of 102° F., which had been preceded by a slight chill. The fever continued about three days. He found no tumor or swelling in the ileo-cæcal region, although he made repeated careful examination of this locality.

On August 17th Dr. S——, husband of the patient, who had been absent from home, returned. He found a normal temperature and pulse.

On the 18th she was up a part of the day, and walked from the bed-room to the sitting-room.

On the 19th she prepared a part of the breakfast. About 10 A.M. she was seized with a severe, sickening pain in the right iliac region, but at a point higher up than at first. A distinct tumor the size of a hen's egg was now discovered, somewhat above McBurney's point, movable and very tender. The bowels moved freely without increasing the pain, which was constant. There was little abdominal distention or tympanites. At times there was free discharge of flatus. The pain at the seat of the swelling was intense, and at times radiated to the stomach and assumed the nature of a spasm, which lasted about a minute. There was no vomiting. She could lie with her limbs extended without increasing the pain.

August 27th.—For the last two days there was rise in temperature from 101° to 102° F. toward evening. The tumor was still high but not sharply defined, no sign of fluctuation, had no chill, no profuse sweating.

August 28th.—The tumor no larger. Bowels continue to respond to salines easily. Yesterday temperature reached 103° F. under tongue at 5 P.M. To day normal at 7 A.M. Relishes her food. Other symptoms unchanged. Her pain was always relieved by one eighth grain hypodermic of morphia sulph., for from twelve to twenty-four hours, and upon the subsidence of pain the temperature decreased. Can lie with limbs extended without increasing the pain. Has had no serious vomiting. Sleeps fairly well. Has taken salines six days, a drachm every hour for six hours, then waited twelve hours

[1] Read before the Omaha Medical Society, January 13, 1894.

and repeated as before. Bowels respond readily, having from six to ten free movements daily. Stools perfectly natural. Has taken a liquid diet of milk, eggs, beef-jelly, and animal broths. She ate watermelon yesterday, and, by accident, swallowed some seeds. They passed to-day without event. The temperature to day has been 102° F. nearly all day. Have given no antipyretic. Fever now (7 P.M.) is subsiding. Gave, at 11 A.M., quinia sulph., gr. vj.

August 29th.—I was summoned by telegram. Reached the patient at 8 P.M. Found a temperature of 101° F.; pulse, 100. Pain in ileo cæcal region. There was a moderate amount of tympanites. A firm tumor was found slightly above the McBurney point. It was painful and very sensitive to the touch; margins could not be defined; was not movable. Very slight tenderness over the remaining abdominal region. During the afternoon there had been a fluid evacuation from the bowels containing a small amount of fecal matter, and presenting an appearance like washings from the colon. A diagnosis of appendicitis was made, and an operation was recommended and agreed to by all concerned. Preparations were made for an operation early the following morning at the home of the patient. All antiseptic precautions were observed in the preparations and during the operation. With the skilful assistance of Drs. Sutherland, Hoge, Spaulding, and Roeder, the patient under ether, an incision was made directly over the tumor, which had become decidedly less distinct during the night.

The peritoneum was opened, the colon presenting. Pushing this out of the way, brought into the field a number of coils of the ileum very extensively bound together by adhesions. The wound was enlarged so as to admit of better inspection. We now discovered what appeared to be a neoplasm, the size of an ordinary fist, irregular on its outer surface, presenting in parts a cauliflower appearance. In this mass were involved several coils of intestine, which seemed to pass through it. It was of a pinkish appearance, semi-elastic in consistency, and only very slightly movable. It was also attached to the inner surface of the ascending meso-colon. This mass presented an appearance identical with that of two carcinomata involving the ascending and transverse colon in the one case, and the pancreas in the other, in both of which cases I had made exploratory laparotomies shortly before, so that I regarded this to be a growth of the same nature. There being so much involvement of intestine, a removal of the mass was considered out of the question. Suitable coils of intestine for anastomosis were sought for, but the adhesions were so extensive that nothing certain could be made out. The abdomen was closed in the usual way.

An unfavorable prognosis was given. From the physical appearance, I believed that the patient would in time succumb either to the effects of a bowel obstruction, or perforative peritonitis, or marasmus due to extension of the growth. Happily this prognosis was not to be realized.

On October 3d I was informed by letter that "her case is a novel one to me. To me she seems to be improving, notwithstanding she has been informed of the gravity of her case."

On October 7th her husband wrote again: "Last Saturday (September 30th) my wife passed per rectum an enterolith about the size of a lemon, of irregular contour, black as tar, and as rough on the surface, and as hard as a piece of broken stone. Since this time she has steadily improved. She is now up, wearing her clothes, and walking about the greater part of the day. For about two weeks after the operation, I had to give her about two grains of morphia during every twenty-four hours, she is now down to one-sixteenth grain in thirty hours. She has a good appetite and sleeps well." She has remained well until the present time, four months after the passage of the enterolith.

In looking back over the history of a given case, in which the objective and subjective signs have been misleading, in which the underlying etiological factor produced appearances not peculiar to it and common to a frequent and well-known affection, we can usually see wherein our error lay. Symptoms, which in the beginning seemed to have a slight or only a secondary bearing upon the case, may have been of great importance. If the proper weight had been given them, they might have so modified the prominent features in the case as to have led to a more accurate solution of our problem. In these days, when the current medical periodicals are teeming with appendical literature, we are apt to lose sight of the fact that other affections than appendicitis can exist in the neighborhood of the ileo cæcum.

Here we had a case of sudden onset of pain which localized itself over the ileo cæcum; elevated temperature, accelerated pulse, constipation, pain aggravated on pressure near McBurney's point. After ten days a tumor, very sensitive on manipulation, was discovered, which existed until a *sectio in vivo* disclosed our error. The clinical picture seemed a typical one. As we critically review the clinical history of our case, now that the mystery seems cleared up, we can find several defects in the chain of symptoms and errors in our methods of examinations. And yet those defects and errors are such that in a similar case we might again be misled.

We find that, after the third day, there was almost complete disappearance of pain, elevated temperature, and accelerated pulse. There was a return of appetite and apparent good digestion. This is unusual, but still might occur in the so-called forms of appendical colic. An elevated temperature and increased pulse-rate are not always evidences of an active inflammatory condition, but may be brought about by severe neuralgic pain, or pain caused by excessive vermicular activity of the vermiform appendix in its effort to throw off a concretion. Having been successful in this, the pain ceases, temperature and pulse-frequency subside, appetite returns.

On the fifth day a tumor somewhat above McBurney's point was found. It was movable and extremely sensitive on palpation. Normal temperature and pulse. Here is the weakest point in our examination. Had I given more weight to the movability of the tumor, we might have drawn a different conclusion. While I did not forget the statement as detailed to me, its importance seemed offset by the sudden onset of the symptoms and the appearance of an abdominal swelling on the fifth day, the usual time for the development of a perityphlitic tumor, where none had been discovered before. The impression imparted to the palpating fingers of slight mobility of an intra-abdominal tumor, is sometimes deceptive. If the neoplasm takes its origin in the mesenterium and its base is toward the posterior abdominal wall, the anterior parietes slip to and fro over the growth as we palpate, making it a difficult matter sometimes to estimate the degree of mobility in such a growth. I have several times opened the abdomen and found the tumor firmly adherent and immovable, where manipulation had seemed positively to indicate that it was movable. I can imagine how an encapsulated perityphlitic abscess, located on the posterior abdominal wall, might give these physical signs.

While an elevated temperature was absent at times, it was found the greater portion of the time. We find, however, that with every dose of morphia the temperature fell to a marked degree and again rose when the effect of the narcotic had worn away—which is not common in inflammatory affections. Free watery stools had no effect for better or for worse, which would not have been the case in appendical abscess.

When I saw the patient for the first time I found what appeared to me a classical picture of suppurative appendicitis. Fever, accelerated pulse, slight abdominal tympanites, a well-defined but not distinctly circumscribed tumor, possibly a little higher than the usual location of the ileo cæcum. The fact that the tumor was higher than usual did not speak against perityphlitis, for I have operated on two cases in which the abscess was located at the costal arch, and one above the crest of the ilium.

Had the leading features seemingly not so emphatically pointed to a suppurative perityphlitis, I would certainly

have used more firm pressure and ascertained the hardness of the tumor, and possibly its mobility. But, feeling certain of the existence of pus, I feared that undue pressure or manipulation might break down limiting adhesions.

In the course of the last eight or nine years I have met with perinephritic abscess, floating kidney, typhoid fever, and intussusception, which sometimes gave us much difficulty in establishing the true condition, but the signs and history did not point with such apparent certainty to perityphlitic disease. Psoas abscess from spinal caries, and abscess with morbus coxarius, which had perforated the cotyloid cavity, tubal and ovarian disease were encountered in this locality, but the diagnosis was usually not difficult.

I recently cut down on an enlarged gall-bladder which occupied a position directly under McBurney's point. Pulse, temperature, local tenderness, sudden onset of symptoms all pointed to an appendicitis. When the patient had been completely anæsthetized I found the tumor movable, and appendicitis was excluded. A distended gall-cyst, which dragged the liver down with it, was found. A cholecystotomy was done, the patient making a good recovery.

It is interesting to note the next error in our diagnosis. After a free opening and an ocular inspection we discovered a firm mass, irregular on its surface, bearing a striking similarity to epithelial growths which I had before encountered in my abdominal work. We can now explain this singular appearance as due to the lodgement of the irregularly shaped enterolith (which had been in course of formation for an indefinite period of time) at the ileo-cæcum; possibly the ileo-cæcal valve was not of sufficient calibre to admit of its free passage. Its rough exterior, in all probability, produced defects in the mucosa, setting up a localized enteritis and peritonitis, causing considerable thickening of the gut walls, producing adhesions between several intestinal loops. The irregularities on the surface of the tumor corresponded to the irregularities of the enterolith.

This enterolith no doubt had been in the course of formation for a considerable length of time. It had not made itself manifest until the moment when it became dislodged from its original position and assumed a new one that was not at all suited to its size and contour, producing a trauma of the intestinal wall which undoubtedly was responsible for the sudden and intense pain.

I have never, in my experience, nor in the literature on the subject, met with an enterolith simulating appendicitis.

UNIQUE PATH OF A REVOLVER BULLET.

By LOUISE RUSSELL, A.M., M.D.,

VAN, TURKEY IN ASIA.

On September 11, 1893, Sathanig B——, an Armenian girl, sixteen years of age, was shot in the right arm by a bullet fired from a small revolver, held about six feet from the arm. When seen the following morning it was found that the bullet had entered the ulnar aspect of the forearm, about three inches below the inner condyle of the humerus, and half an inch toward the median line. From the shoulder to the finger tips the arm was swollen to more than twice the size of the left, and the hand was slightly œdematous. The bullet had made a clean entrance, having cut the cotton sleeve like a sharp knife. On probing, the path led inward toward the ulna, and slightly upward toward the joint, but beyond an inch and a quarter the probe refused to pass. All the fingers were numb and tingling, except the fifth, where sensation was normal. All motions of wrist and fingers were possible, though with pain; and the elbow was immovable. The arm was immersed in hot water, and morphine given for the pain.

On the 12th the swelling had slightly decreased. The patient had been very uncomfortable during the night, sleeping only when under morphine. A drain of sterilized cotton was inserted, and the arm dressed with iodoform.

On the 14th the swelling had diminished one-half, and pus had begun to flow. Temperature, 103° F.; pulse, 128. Pain was still severe. Five grains of quinine sulphate were given, and a wet bichloride dressing applied.

On the 18th the swelling was confined to the region about the elbow. Pain had practically ceased. Temperature was normal, and the pulse was 80. The skin over the lower four inches of the triceps was intensely discolored, and the tissue was indurated. Movements were free at wrist and all finger-joints, and there was slight motion at the elbow, extension being somewhat freer than flexion. There was slight induration in front of the elbow-joint. Pus had ceased to flow.

On the 21st the condition was as above, with slightly more motion, and an indistinct sense of fluctuation over the olecranon. The external wound was entirely closed.

On October 7th the arm had resumed a normal appearance, except that about a square inch of the olecranon region retained its discolored hue. Sensation was normal, save a slight numbness persisting in the thumb. The induration at the elbow prevented flexion beyond eighty degrees, and extension was similarly limited. The patient was instructed in passive motions, simple rubbing was ordered, and she was told to wear the left arm in a sling half the day.

On December 19th she came to the office to exhibit her triumph. The appearance of the arm is perfectly normal. Motion is free, the only limitation being a slight pull on putting the hand well behind the head. There is no pain or tenderness. On deep pressure on the middle of the triceps, one inch above the olecranon, the bullet can be distinctly felt, deeply embedded in the muscle. How did it get there without any real injury to the elbow joint? It appears to be an excellent example of the *laissez-faire* policy in surgery.

DISAPPEARANCE OF GONORRHŒAL DISCHARGE DURING PNEUMONIA.

By A. HYMANSON, M.D.,

NEW YORK.

While I served as interne in the Beth-Israel Hospital, I observed a case which is similar to the one described by Dr. Bogdan in the *Wiener Medizinische Presse*, and reprinted in the Medical Record of January 20th.

On April 11, 1893, Nathan G——, pedler, aged eighteen, was admitted into the above-named hospital with a pneumonia of the left lung. While giving the history he stated that several days prior to his present illness, on April 2d (about the fifth day after exposure) he had for about three days violent pain on micturition, and a profuse creamy discharge. As soon as he began to cough the discharge had gradually declined and the pain and frequent urination subsided. The patient did not consult a physician for his urethral trouble, and from his description I suspected him to have a mild case of gonorrhœa. I examined him repeatedly, but no discharge has been detected. There was some redness at the lips of the meatus. The urine was of alkaline reaction; it had a specific gravity of 1.020 and contained slight traces of albumin. On the eleventh day, on the beginning of convalescence from the pneumonia, the boy called my attention to the reappearance of the discharge, which was of a real gonorrhœal character, and he also had some pain on urination.

207 Madison Street.

The Physio-Medical College has won the first round in its fight with the Illinois State Board of Health. It obtained, on January 20th, an injunction restraining the State Board of Health from incorporating in its annual report any statement reflecting upon the standing of the college.

Progress of Medical Science.

The Increase in the Microbicide Power of the Blood during Infection.—Dr. Gatti describes some experiments undertaken with the view of elucidating this point. The existence of a microbicide power in the blood and serum is generally admitted, and research is now directed to the discovery of its relation to susceptibility or otherwise to infectious disease. The present researches have been directed, not only to a demonstration of the existence of a microbicide power during infection, but also to the modifications which this power undergoes in a given animal during its passage from health to a condition of infection. Omitting the details of the experiments, the author's conclusions are as follows (*The British Medical Journal*): 1. A moderate degree of hydræmia, such as is produced by the extraction of blood, does not modify the bactericidal power of serum. 2. Serum represents a much more constant means of seeking bactericidal power than defibrinated blood, the results with this latter being inconstant, as has also been found by Kruse and Pansini. 3. The bactericidal power of blood increases during infection; this increase is more marked in animals which during health do not show a very great bactericidal power. 4. In the later phases of infection the microbicide power diminishes. 5. The blood destroys not a determinate quantity of bacteria, but a given percentage of the bacteria introduced. 6. There exist markedly different degrees in the bactericidal powers of different animals, even of the same species and for the same micro-organism. 7. In the latest phases of infection the bacteria introduced into the blood disappear but slowly and incompletely, as compared with what happens in the earlier phases or in the healthy animal. 8. In many animals the serum does not at once manifest its bactericidal powers, but there is first a period of one or two hours during which the bacteria introduced can increase. The most important fact elucidated is undoubtedly the increase of bactericidal power during infection. The conditions of experiment, moreover, render it unlikely that this result can have been due to extra-vascular modifications of the blood; it is a true vital phenomenon. Its increase during infection, at a time when the organism is reinforcing itself against the invading microbe, and the coincidence of its diminution with the time which, as it were, succeeds the successful battle, make it probable that there is a very intimate connection between this power of the blood and immunity.

Med. Record

Workers and Weariness.—Professor Michael Foster has published his Rede lecture in the current number of the *Nineteenth Century*. Weariness is his subject, and it is one which demands the intelligent thought of all people of the present day. We recently called attention to the insanity which refuses to recognize weariness as the most dangerous symptom of mental fatigue. It may be true or false that the world will not see the year A.D. 2000. It is, however, undoubtedly true that the Mother of Parliaments, as the present House of Commons delights to call itself, is being rapidly reduced to a state of impotence which threatens the national safety. It is notorious that very old and very young people frequently have abnormal energy which spurs them on to acts of foolhardiness, which may, and frequently do, have a fatal termination. It would be impossible for any business undertaking of importance to be conducted successfully on the principles which at present govern the conduct of business in the House of Commons. Those principles as laid down by the Premier in the resolution of which he gave notice for Monday, and which were to apply to the rest of the present and the whole of the autumn session, could have but one result. In its modified form it is fatal to all useful legislation. That it was not strenuously opposed proves to demonstration the condition of weariness to which Members of Parliament have been brought. Any legislation pushed forward by the continuous use of the spur and the whip must prove defective and harmful to the well-being of the people. Members of Parliament being men are subject to physiological laws as all are, and the absence of proper rest, and the refusal to conduct business within reasonable hours can only result in breakdown and disaster. The plan of business formulated by the Premier is opposed to every principle which enables any average mortal to master his work and maintain his health. In an ordinary business any such experiment as that about to be tried upon the House of Commons would very properly end in bankruptcy. We are no doubt a long way removed from national bankruptcy, but the ship of state is now within measurable distance of irreparable damage and discredit. This is not a political journal, but common-sense makes it apparent that the well-being of the people and the State demands the prompt presentation of a monster petition to the House of Lords not to pass the Appropriation Act, and to the Queen, urging the exercise of her prerogative, by the immediate dissolution of the present House of Commons.

Let us now see what Professor Foster has to say on the subject of weariness and its effects upon men and women. It is a popular belief that weariness is a physical symptom alone; that is to say, people become tired because their muscles are weary, whereas, in truth, muscular weariness depends not on the muscle alone, but on the manner in which the muscle in its work is aided and supported by the rest of the body. "The blood, sweeping throughout the whole body, washes out of the muscle all hurtful bodies, providing always the blood-stream is pure. If the blood-stream be sluggish, or if the blood coming to the muscle be already loaded with hurtful bodies, the clearance is slow or wholly fails, and weariness comes on apace. But even the simplest and rudest muscular tasks are not carried out by the muscles alone, for the brain and the nerves share in them too. It is a common experience that when we are weary almost, it may be, to death, some sudden emotion, some great joy or fear, may spur us to an effort which just before seemed impossible; conversely an emotion may appear to take from us all our muscular strength. Now the muscles neither know nor feel; their weariness cannot be affected by any emotion. That weariness which is put aside by hope, or which is hurried on by despair, must be a weariness not of the muscles, but of the nervous system." It would be interesting to follow Professor Foster as he goes on to prove the difference between the brain and the nerves, the brain being, of course, the central mechanism, the nerves mere bundles of fibres which carry the impulses to the muscles. We must, however, refer our readers to the article itself for this and other information, and would direct their attention especially to the experiments by which Professor Foster proves that the greater part at least of weariness is begotten not in the muscle, but in the brain.

Let us now consider a few of the mental symptoms of fatigue or weariness. Professor Foster insists that two facts must be grasped and remembered. While it may be said of each member that the blood is the life thereof, it may with equal truth be said the blood is the death thereof; the blood is the channel for food, but it is also the pathway for poison. Again, all our knowledge goes to show that the work of the brain, like the work of the muscles, is accompanied by chemical changes, that the chemical changes, though differing in details, are of the same order in the brain as in the muscles. It is true that the changes in the brain are smaller than those of the muscle, but this is counterbalanced by the exceeding sensitiveness of the nervous substance; the last fact giving point to the caution that to do the maximum of brain-work it is essential not to render the brain more agile, but to encourage its humble helpmates so that their more efficient co-operation may defer the onset of weariness. Mind and body being thus intimately associated, no sensible person will risk the destruction of health by neglecting either the one or the other. Sleep, good food, healthy surroundings, rational hours of work, and sufficient exercise, are points which many people have long recognized as essential to their well-being; yet the race for wealth, or for political

advancement, or the mere struggle for existence, may cause the most enlightened to neglect them. At first a man so circumstanced attributes his lassitude, which is usually confined to the early morning, to anything but the right cause—a feeling of depression and a sense of ill-being may make him miserable, but unless his doctor takes him in hand they will not check his downward course. Next he will become oppressed with the need of increased effort, a loss of memory, and the difficulties of remembering what he reads. To this point a man may advance without fatal injury, but should he proceed until everything appears to him dark and hopeless, a worry and an apprehension, then he may be beyond rescue, and his next step may land him in a lunatic asylum if it does not terminate earlier in a graveyard.

Dr. Cowles, of the McLean Hospital, has written a most interesting paper on the mental symptoms of fatigue, which all brain-workers should read. He shows in a practical way how difficult it is to restore the weary to energy and strength. Overworked women, professional men, politicians, and others, "work on their nerves," and say they "don't feel tired, and nothing is the matter." Many of them, indeed, insist that they feel better when actively pursuing their ordinary occupations. Dr. Cowles declares this condition, which comes on insidiously, to be a most dangerous one. With the impairment of the natural fatigue sense the mental effect is that a man will not believe even his physician's diagnosis of fatigue. He is, therefore, prone to look for some other reason for his sense of ill-being and inefficiency, and finds in retrospection cause for self-reproach and hopelessness in the future, or insists upon a revolution in his affairs as the only remedy for a condition of which he himself is the central cause. Here, then, we arrive at the two great factors which have to be faced to-day in our national and political life. The first, or retrospective cause, lies at the root of the present epidemic of suicide of which the papers are full. The second, or impairment of judgment cause, lies at the root of the political *impasse*, which its authors declare can be cured only by revolution. The papers of Professor Michael Foster and Dr. Cowles are therefore most timely, and if the lessons they teach can be driven home they may prove fruitful by producing a more natural and healthy tone, not only in our Parliamentary, but in national life too —*The Hospital.*

Speech for Deaf Children.—In an article with this title published in the January number of *The Popular Science Monthly*, Miss Lillie Eginton Warren, of New York, a teacher of the deaf, says: "Less than thirty years ago, no attempts were made to give speech to the deaf children of this country. Now correct, fluent utterance, with voice more or less agreeable, and the ability to understand others by watching the facial expressions, may be acquired by the boy or girl suddenly deprived of hearing or born deaf. The look of the very young deaf child is usually an interested one, accompanied by fewer unnecessary movements of the eye and less play of the facial muscles. From increased observant faculty comes a marked development of the imitative functions. The child's hands spring to his help. He goes through motions that he has noticed those about him use; in their case, however, speech and lack of observation have kept them from consciousness of those movements. They begin to see his, they are unaware of theirs; to them, the child has invented his own signs. Touch, taste, and smell come quickly to his aid. The lack of facial expression gives place to grimaces, and an unconscious play of the vocal organs forms a series of more or less unpleasant grunts and screams. The child must be taught to obey promptly, and his punishment be of a kind to win his respect. Reasoning from limited knowledge, gathered by his observation alone, he misunderstands many efforts to do well by him. Give him the speech he knows not, and the language that is to him a sealed book.

"It is possible to develop an agreeable voice if proper action of the edges of the glottis is secured. The voice formed in the larynx is moulded into the numerous vowels by the various shapes assumed by tongue, lips, and soft palate, and into consonants by decided actions of the same organs. Vowels are the life of speech; in them lies expressive voice. Vowels and consonants combined, forming words, can be learned as rapidly as they can be memorized. It is necessary to explain their meanings by the child's natural signs; consequently his first spoken and written words must be equivalents of the same objects he has designated by a gesture, of the daily actions about him, of the qualities he has appreciated by taste, touch, and smell. Single words thus become intelligible to him. He drops the sign and speaks. Now, a new difficulty presents itself. The grouping of words, the forming of phrase and sentence, he has no knowledge of; moreover, when grouped he does not grasp the shades of meaning thus conveyed to the hearing person. All this must be carefully shown him. Various studies can be taken up by the pupil after he has secured some hold of language. There are no limits for him but his inclinations or circumstances.

"If a child loses his hearing when two or three years of age, or when even somewhat older, and no educative means are employed immediately, the articulation becomes impaired in a short time. His knowledge of speech and remembrance of forms of expression in language, if measures are taken at once to retain them, develop into a great advantage over those of the same age who never heard. Speech-reading is an ability to follow the varying expressions in the face as quickly as they appear, and thus to convey thought through the medium of the eye instead of by the hearing. To do so successfully means an education of the eye secured by practice. Its attainment by the child born deaf grows with its knowledge of spoken language; the child who has lost hearing after having learned speech, naturally advances in ability to understand others in proportion to his dependence upon that method of communication; and with the adult losing his hearing power, speech-reading becomes a high degree of expression-reading, enabling him to follow his vocation and pleasures, save those requiring a somewhat sensitive condition of the auditory sense. Many children are deaf because of a slow perception of sound, not altogether due to aural defects. They must be taught to listen, for without the strain of attention the loudest noises may be unheeded.

"With speech and speech-reading attained, and perhaps the happy addition of some perception of sound, the deaf need not be thrown together as a class distinct from others. They may and do receive instruction in common with their hearing friends, attending leading schools and entering professional duties side by side with them. A preference for the companionship of the hearing proves the existence of a satisfying method of communication."

Higher Requirements for Entrance to Medical Colleges.—The Illinois State Board of Health has amended the schedule of requirements for admission to medical colleges by taking out of the hands of the college the examination in the elementary branches of education, and requiring either a certificate or diploma from a literary and scientific college or high school or, at least, a second-grade teacher's certificate. A curriculum of studies for schools of midwifery was also adopted. A committee was appointed to draft an outline of sanitary work throughout the State, and the secretary was ordered to issue a "preventive disease" circular on tuberculosis. The officers were re elected as follows: *President*, Dr. William E. Quine, of Chicago; *Secretary*, Dr. J. W. Scott, of Springfield; *Treasurer*, Dr. B. M. Griffith, of Springfield. The Governor has reappointed Dr. Julius Kohl, of Belleville, a member of the Board.

Physicians of India are reported to have addressed a communication to the International Medical Congress to meet in Rome, asking for the establishment of a medical journal in the Latin language, for the preservation to all eternity of important medical writings in abstract.

MEDICAL RECORD:

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, March 3, 1894.

A NEW TREATMENT FOR TUBERCULOSIS OF THE JOINTS AND SKIN.

IN the *Edinburgh Medical and Surgical Journal* for February, 1894, Mr. A. G. Miller reports the results of his treatment of strumous affections by means of passive congestion. The treatment originated with Dr. Bier, of Kiel, one of Esmarch's assistants. It was suggested by the old belief, supported by Rokitansky, Laënnec, Niemeyer, and Fagge, that "all cyanosis is incompatible with tuberculosis." This dictum, though originally applied to the lungs, was thought to be equally true for joint and skin tuberculosis.

The technique of the method is simple. It consists in placing a broad elastic band round the affected limb, a few inches above the diseased part, firm enough to produce venous congestion. Bier recommends that this congestion should be kept up continuously, and that the patients should be permitted and even encouraged to use the limb. The elastic band should be broad, and a layer of lint or wool should be placed under it to protect the skin. The point of application should also be changed every day or two to prevent abrasion. The distal portion of the limb is supported by a common roller up to the affected part, so that the congested area is limited to the immediate neighborhood of the disease.

No other apparatus or treatment is employed by Bier in his cases. As an example of the method of application, take a case of disease of the elbow-joint. The hand and forearm are bandaged, then the elastic is applied to the middle or lower third of the upper arm, firm enough to produce congestive discoloration of the neighborhood of the elbow. Congestion is what is wanted, not œdema, still less anæmia. Pain is never caused, and if the compression be uncomfortable at first, the patient soon becomes accustomed to it.

An account of Bier's method is given by him in the *Centralblatt für Chirurgie*, 1892 (Beilage No. 32, p. 57).

He records upward of twenty cases that were treated in Professor Esmarch's wards at Kiel by this method, and reports that "in most of the cases the improvement attained was very rapid and striking, and in no case did a change for the worse occur.

The method was first tried in London by Mr. Herbert Page, who came back from Kiel with much enthusiasm over the results he had seen.

The plan employed by Mr. Miller at first was to put on the elastic compresser for only ten or twelve hours every alternate day—that is to say, the bandage was put on in the morning and removed at night, and left off altogether for thirty six hours. He was afraid to risk the continuous congestion of the limb.

His experience was that venous congestion was quickly produced and maintained without any discomfort to the patient. Œdema was seldom seen. He always employed some other apparatus, however, for supporting or fixing the diseased part when a joint was affected. Improvement occurred promptly both in joint and skin affections, but more surely in the latter class of cases. Although Mr. Miller had used the method for about six months, he speaks cautiously regarding it, since, as he says, he did not have time enough to watch the results of a congestion treatment alone. He prefers the alternate to the continuous treatment, and he thinks he is justified in recommending its use in :

1. Tubercular skin affections of the extremities.
2. Early tubercular disease of joints (combined with immobilization or blisters), especially those in which time is of no great importance.
3. Instances of multiple tubercular disease, in which more radical treatment is inappropriate.

WATER, THE ANCIENT AND READY REMEDY.

THE recent sensational announcement in the newspapers that the priest of Woerishofen has been consulted by so eminent a personage as the pope, emphasizes the trite saying that "history repeats itself."

Water has been an orthodox and highly esteemed remedy since the day of Hippocrates, who wrote a tract upon it. It is to-day probably applied more freely and more successfully by educated physicians than at any previous time, in acute and chronic diseases. It is not surprising, therefore. that empirics have not been slow in availing themselves of so effective a remedy.

In the days of Ambroise Paré (1553), the wounded at the siege of Metz often preferred the ministrations of a certain Maître Doublet to those of the illustrious surgeon who had revolutionized wound treatment. Doublet treated the wounded with cold water and lint, murmuring certain mystic formulæ while making the application. Paré quickly discovered that, "the good results were entirely ascribable to the water, which cleansed the wound and by its cold protected it against inflammation."

It is interesting in this connection to note that, two hundred years later (1785) the eminent surgeons, Lombard and Percy, were astonished by the rapid recovery of several wounded men under the treatment of a miller, who applied river water into which he threw, amid incantations, a white powder, recognized as alum. After thoroughly washing the wounds he dressed them with lint dipped into water, while reciting holy sentences. Percy says ("Dict. des Sciences méd.," p. 477 to 480) that this lesson was not lost to him. Such rapid and comfortable recoveries had never resulted from his usual dressings, and his conclusion that pure water would accomplish the same results was soon brought to a test in the cases of thirty-four wounded artillery-men, who recovered in an unusually short time. This eminent military surgeon continued to successfully dress his wounded

with water, and said that, "as Sydenham would not have wished to remain a physician without opium, so would he give up military surgery if deprived of water."

In 1723 an English Protestant clergyman published a book, "Febrifugum Magnum, a common water, the best cure of fever," which lauded this remedy so highly that another layman, Oertel, a learned German teacher, became a convert one hundred years later to his doctrines, which he successfully promulgated among the people.

Again, in 1724, a Capuchin monk, Pater Bernardo, living in Sicily, performed "wonderful cures" with water. Despite inadequate means of diffusion his fame spread all over Europe, just as that of Kneipp does to-day. Bernardo was followed by Todana, who was dubbed medicus per aquam, and Sangez, who was medicus per glaciem, because ice was his universal remedy.

About the year 1830 two of the most arrant quacks created a great sensation in Germany by reason of their astounding cures with water. Bleierle, a bath attendant, and Schatz, a journeyman shoemaker, set the world agog as Kneipp is doing to-day. The greatest water empiric which the world has produced is Vincent Priessnitz, who lived during the first half of the present century. What men like Currie and Hufeland could not accomplish, this simple Silesian peasant attained with ease, by the popularization of water as a remedial agent. "The impression made by this empiric marks an epoch in hydrotherapy. His success was brilliant because he was a careful observer, a good judge of human nature, and his mechanical skill enabled him to invent various technical modifications of the water treatment, many of which have been adopted by the profession in all parts of the world. The government built roads to facilitate access to his establishment; monuments and fountains were erected to his memory. Physicians from all countries, who had been attracted to the Silesian peasant's mountain home, became converts to and missionaries of his practice. In 1840 he treated over 1,500 patients from all parts of the world, and when he died, twelve years later, he had amassed a fortune of several millions." This extract from the "Uses of Water in Modern Medicine" p. 9, reads now much like the record of Kneipp's life and work. At the present time there is a large number of laymen, especially in Germany, who practise as naturaerzte, using no medicine whatever, but relying upon water as the chief remedy, which they supplement by the more or less crude application of diet, exercise, and other hygienic measures. The success which has attended these empirics has emboldened them to compete with educated medical men.

In the interest of his clientèle, it behooves the practitioner to devote at least as much attention to the clinical study of water as he does to the investigation of medicinal remedies. Only by this method will the profession be enabled to successfully meet the encroachments of empirics like Kneipp. The latter, it may be mentioned, differs from Priessnitz and his other predecessors in that his methods are less heroic, and in his prescriptions of various herbs, oils, and medicines like camphor, alum, aloes. Kneipp claims that diseases are due to disturbances of the circulation or in the blood by admixture of foreign matters. These are met by steaming with or without herbs to produce resolution; by cold compresses and ablutions to induce elimination, and by cold baths, douches, and ablutions for invigoration of the organism. The colder the water the more effective, if it be not applied unless the body is warm. "The greater the preceding perspiration the more effective the cold bath," says Kneipp, and herein he follows Priessnitz, and indeed the educated hydrotherapeutist. Kneipp counsels running barefoot in snow or dew-covered grass as a hardening measure. This was recommended also by Priessnitz. Kneipp never orders warm baths without succeeding cold ablutions.

A peculiarity of the Kneipp method is that he does not dry his patients, but depends upon the rapid donning of linen underclothing and subsequent exercise for producing reaction. He is an enemy to woollen undergarments. The chief element of success in the practice of this simple priest, is probably the fact that he utilizes the true principles of hydrotherapy in a crude manner, the other elements being suggestion and the removal of the bad dietetic and other non-hygienic habits of the patient.

COLLEGE ATHLETICS AND THE DRINKING HABIT.

President Eliot, of Harvard University, has made the following recommendations as to the regulation of college athletics: 1. There should be no Freshman intercollegiate matches or races; 2, no games, intercollegiate or other, should be played on any but college fields, belonging to one of the competitors, in college towns; 3, no professional student should take part in any intercollegiate contests; 4, no student should be a member of a university team or crew in more than one sport within the same year; 5, no foot-ball should be played until the rules are so amended as to diminish the number and the violence of the collisions between the players, and to provide for the enforcement of the rules; 6, intercollegiate contests in any one sport should not take place oftener than every other year. Finally, if trial shall prove the insufficiency of all these limitations, intercollegiate contests ought to be abolished altogether.

These recommendations are surely in the right direction, and we heartily trust that as many of them as possible may be carried out.

There is perfect unanimity of opinion regarding the value of college athletics; but the excesses to which they have been carried are notorious, and the time has come for some decided reform.

The praise of exercise and training has been sung so systematically and enthusiastically, that most people have come to believe athletic sports and sound health to be almost identical things. As a matter of fact, athletic exercise is not always needed, not always beneficial, and is sometimes pernicious. Life insurance examiners agree that professional athletes are short lived; while amateurs may, or may not, have a long and healthful life. Those whom vigorous exercises would help most, are often the very persons who do not indulge in them.

But there is another feature of college and amateur athletics which is of serious character, and which has been little dwelt upon. This is the drinking habit which so often accompanies active exercise. College students, if we are correctly informed, are very largely beer-drinkers, while spirits are used also to a considerable extent.

Yale students are said to be particularly fond of beer, while Harvard men possess a wide and deep fund of prac-

tical knowledge about cock-tails. We cannot, of course, say that the drinking habits would not have increased without athletics. But hard exercise creates a thirst which strongly tempts to malt liquors and stronger beverages. The relation of alcohol to athletics is an extremely important one, and one that we are confident has not been sufficiently regarded in attempting to estimate the exact value of athleticism. Probably nine out of ten college students practically give up athletic sports after graduation, but they do not give up their drinking habits.

THE EVOLUTION OF MEDICAL JOURNALISM.

It is extremely profitable to watch the gradual implantation of the methods of modern lay journalism upon current medical literature. A regular feature of some monthlies is now a picture of some celebrated local physician, accompanied with a flattering biography and an appreciative editorial notice, for which fifty copies are subscribed; a conundrum column where the guesser gets a prize; an illustrated humorous column adorned with strictly medical wit; a urinary chart or a hypodermic to each new subscriber. All these are new features which unite to add to the attractiveness of our science the purity of our literature and the gayety of our art.

An Ohio journal has, however, quite outstripped its competitors recently, by devising a system of periodical rewards and continuous though ectopic attractions which indicate an apt and fertile mind. To every subscriber there will be sent a "surprise package" every three months, these packages to consist of some modest but useful article that is sure to prove valuable to the physician. But this is not all, nor even half. The editor proposes to provide a new form of literature for his readers in the shape of prize stories, of which the incidents will be grouped in a familiar professional atmosphere. A standing offer is made of various sums of money to be given for first, second, and third prize. Our contemporary bids fair to create a new literature of medical realism. It wants seven thousand subscribers, but it is too modest.

THE JUBILEE OF A VIVISECTIONIST.

To the anti-vivisectionist Professor Moritz Schiff represents all that is diabolical in human nature. Yet, strange to say, he is found by those who know him to be a man of amiable and humane character, as well as a profound scholar, and an original investigator. On no other grounds could his recent jubilee have been such a successful demonstration of respect, admiration, and affection. Of this *The Lancet* says:

The magnificent demonstration organized on January 24th by the Geneva Medical School in honor of Professor Moritz Schiff having attained the fiftieth year of his scientific life deserves more than the passing notice already given. A knight errant of biological research, Schiff had barely graduated at Göttingen in 1844, when he gave to the world his treatise "De Vi Motoria Baseos Encephali," in which, independently of the physiological truths established, he showed himself a master of the inductive method. His early familiarity with the processes of the laboratory was reinforced by philosophical study, for, as he told his Geneva audience on the interesting occasion of January 24th, he schooled himself in the Platonic metaphysics, beginning with the "Phædro," while pursuing his researches into nature.

After teaching at Berne, he accepted a professorship at Florence. Driven from that school by the anti-vivisection faction after five years brilliant and most useful work, he was invited to the professorship of Physiology in Geneva, where he has labored and taught ever since. How deeply the Florentine School deplored the loss of its kindly German colleague was shown in *The Lancet* of February 4th of last year, in which a message of congratulation, couched in admirable Latin, was published from the professorial staff of the Istituto on his reaching his seventieth birthday; but to whatever nationality his pupils and brother teachers belonged, he equally conciliated their respect and devotion, a result brought remarkably into evidence at the demonstration of the 24th ult. Of all the tributes that came to him by telegraph, or post, or personal conveyance on that auspicious day, none was so gratifying as that handed to him by a former pupil, Professor Herzen, of Lausanne. This was the first volume of a collective reprint of his papers and articles contributed during the last fifty years to scientific periodicals, during which the famous lectures "On Carlo Matteucci: his merits in Physiological and Medical Physics," which appeared in *The Lancet* of July 22 and 29, 1876, are destined in due course to be included. The expense of the publication was met by subscriptions of old pupils scattered over the medical world, mainly in the continent of Europe, and its value as supplementing and completing such well-known *chefs-d'œuvre* of his as the "Lehrbuch der Physiologie des Menschen," the "Leçons sur la Physiologie de la Digestion," and the treatise "Sulla Misura della Sensazione," written with equal grace and force in German, French, and Italian, has but to be indicated to be appreciated.

We are told that two-thirds of a man's character is determined by his work and environment. Professor Schiff is receiving evidence of esteem and affection from all over the world, and he deserves it all.

Death of Professor Hirsch, Berlin University.—This distinguished physician and pathologist, and Professor of Medicine in the University of Berlin, died recently, at the age of eighty-three. During his earlier career as a general practitioner he made extensive researches into the history and geographical distribution of malarial fever, typhoidal maladies, dysentery, and analogous complaints, and embodied his conclusions in a work of two volumes, entitled "Hand-book of Historico-Geographical Pathology," by which Professor Hirsch was regarded as the founder of the study of the geographical distribution of disease, which also secured to him in 1863 the appointment of Professor of Medicine at Berlin University. In 1873 he was a member of the German Imperial Cholera Commission, the appointment of which was largely due to his initiative, and in the following year he represented Germany at the International Sanitary Conference of Vienna. For his services on this occasion he received the title of Medical Councillor. Among the many works on special subjects written by the deceased was a History of the Epidemics of the Middle Ages, amd an important text-book on diseases of the eye.

News of the Week.

Successor to Professor Moleschott.—Professor Luigi Luciani, of Florence, has been appointed to the Chair of Physiology in the University of Rome, to succeed Professor Moleschott.

Award of the Riberi Prize.—The Riberi Prize, founded by Professor Alessandro Riberi, has just been awarded to Dr. Camillo Golgi, Rector of the University of Pavia, and Professor of General Pathology, for his essay upon Malarial Fever. The prize amounts to $4,000, and is open to international competition every five years. The subject must be one of purely medical interest, and the essay be the result of original research. There were three essays this year deemed worthy of final consideration, that by Dr. Golgi being finally awarded the prize. The others were by a Frenchman and a German.

A Bequest to the Harvard Medical School.—The will of Rev. William C. Moseley, of Newburyport, bequeaths $50,000 to Harvard College, to endow a professorship in the Medical School. Other bequests in the will were $20,000 to the Massachusetts General Hospital, for beds in memory of his son; $10,000 to the Boston Lying-in Hospital; $10,000 as a trust to the Perkins Institute for the Blind; and $10,000 to the Anna Jacques Hospital, of Newburyport.

Action of the Association of American Medical Colleges on the Question of a Four Years' Course.—A committee of the Association of American Medical Colleges, met in Chicago on February 7th. The meeting was called to order by Dr. P. H. Millard, the Secretary. The Association represents seventy-one medical colleges, and the object of the meeting was to act upon a proposed amendment to the constitution providing for the adoption of a four years' course. There were present fifteen members. Dr. Millard said: "In response to the circular letter, sent out by myself, I have received information or advice from twenty-eight colleges in regard to their wishes or desires for the four years' course, and I can state definitely that twenty of these colleges are in favor of the adoption of the four years' course at this time, or at the San Francisco meeting, to be held in June next; that two colleges are endowed, and four or five colleges are opposed to it at this time, deeming it impracticable so shortly after adopting the three years' course; one college making the proposition that they will support it if we make it apply to 1896 instead of 1895."

After some discussion the following resolution was adopted:

Resolved, That this committee recommend to the Association of American Medical Colleges at its next meeting in June, to be held in San Francisco, that no medical college shall be permitted to remain or become a member of the Association that does not provide, either for a three years' course of eight months' study, or a four years' course of not less than six months each, to take effect in 1895. This was carried.

The Secretary moved that a committee of five be appointed to prepare a curriculum of studies, providing for the minimum of time and lectures to be devoted to each one, and that the committee report at the San Francisco meeting. This was also carried.

The Chairman appointed on this committee Drs. Davis, Connor, Quine, Stemen, and Vaughan. The Committee then adjourned.

The New Hospital at Sing Sing will shortly be opened. It is intended to take the place of the old St. John's Riverside Hospital.

Head Measurements and Longevity.—People will begin to measure their heads with most anxious care now that a physician has found its size to be an index of longevity. A person, says Dr. Morris, with a head whose diameter at the thin portion of the temporal bones measures five and a half to six inches is almost sure to give a longevity on the father's side of seventy to ninety years or over. If the head measures in front, from the external auditory canal to the naso-frontal suture, as much as four and three-fourths or five inches, we may be almost sure of long life on the maternal side. This will be great news to the people who wear 7¾ hats. Chicago is said to be already tumultuously congratulating itself.

The Army Medical School. — The Army Medical School closed its first term in Washington, on February 28th. There will be appropriate ceremonies attending the event. The initial course has proved very successful, and of material benefit to the newly appointed Assistant Surgeons, for whose instruction in military surgery and the general duties the institution was organized. There are five passed candidates who have attended the school regularly for all the courses. Several of the younger officers of the Army Medical Corps have attended some of the sections, and one took his two months' leave, the first he had been granted in some time, and employed this leisure in listening to the lectures at the school. It is likely that in another year, as the opportunities for instruction increase, the purposes of the institution will be enlarged. There is a proposition to make the results of the school further reaching than at present.

An Attempt to Lower the Fees for State Medical Examinations.—The Committee on Legislation of the Medical Society of the State of New York has sent to the Senate an argument, which is complete and unanswerable, against the proposition to lower from $25 to $5 the fee for a medical examination. This proposition has been embodied in two bills that have been introduced into the Assembly and that have no merit whatever. A good many people are of the opinion that entry into the medical profession should be made rather more difficult than more easy, and that the fee now exacted of candidates would not be too great, even if it were covered into the State Treasury. But the protest of the State society does not proceed upon this ground at all. It shows that the present requirement of the law was adopted only after mature consideration and after a long struggle, and that the fees now exacted do not more than suffice to pay the expenses of examinations.

A New Training-school for Nurses.—The new building for the Training-school for Nurses, which is attached to the German Hospital and Dispensary, was formally opened last week, and a reception was given by the Board of Trustees to celebrate the occasion. The new building is a five-story structure, built of pressed red brick, and is fire-proof. It is well lighted, having windows on all four sides, and is furnished with an elevator and all modern improvements.

Dr. T. Cranstoun Charles, Lecturer on Practical Physiology at St. Thomas's Hospital Medical School, died on January 24th, in the forty-fifth year of his life. He was the author of a Handbook of Physiological Chemistry.

Consultants May Receive Legacies.—There is a clause in the civil code of France which forbids medical men from receiving legacies from patients whom they have attended during their last illness. A case has recently been decided in a French law court, in which a legacy bequeathed to a medical man who had been called in, in consultation, during an illness which ended in the death of the patient, was withheld on the ground that it was illegal. The Court, however, judged differently, on the ground that the medical man in question attended the patient only during a short period of the illness, and in consultation.

Vaccine Carried by Pigeons.—An army surgeon, Dr. Hoebel, has sent small-pox vaccine from Fontenay-le-Comte to Rochelle by carrier pigeons. In the tube of the median feather, instead of a despatch, small tubes of vaccine were placed, steadied by the under portion of lucifer matches. The tubes arrived in perfect condition in fifty-five minutes. Carrier pigeons in war time may thus arrest a small-pox epidemic.

The Number of American Physicians.—In a late issue of the *Railway Age*, Dr. R. Harvey Reed makes the statement that, if there be abstracted from the profession the railway surgeons, the army, navy, and marine hospital surgeons, the insurance and pension examiners, the hospital staffs, and "like distinguished personages," so few will remain that "it will require a military band to muster them close enough together to be seen with a fifth-objective microscope." According to this, the membership of the Association and the entire profession is practically composed of those holding distinguished offices of honor and profit. We are told by Polk's "Medical Directory of the United States" that there are over a hundred thousand doctors in the United States, and we are rather staggered to be informed that, aside from those holding official positions of honor or emolument, there are not enough doctors to occupy the field of a fifth-objective microscope.—*Journal of American Medical Association.*

Mathew's Medical Quarterly is a new journal devoted to diseases of the rectum, gastro-intestinal diseases, and rectal and gastro-intestinal surgery. It is edited by Drs. Joseph M. Mathews and Henry E. Tuley, and published in Louisville, Ky.

Blue Glass and Red Glass.—There is a report that red glass is to be tried in one of the small-pox pavilions at North Brother Island, New York, in order to test the value of the experiments made by Drs. Lindholm and Vinsen, of Bergen, Norway, who claim that the pitting of small-pox patients is due to the sensitiveness of the skin to violet rays of light. This reminds us of a chapter in the history of medicine which interested the world a dozen years ago. It was in 1881, as we remember, that there was published in Philadelphia a book entitled, "The Influence of the Blue Ray of the Sunlight and of the Blue Color of the Sky in developing Animal and Vegetable Life, in Arresting Disease, and in restoring Health in Acute and Chronic Disorders to Human and Domestic Animals." On the front page is this quotation: "If this be true, it up sets all theories." It treats of the electro-magnetic power of the sunlight transmitted through blue glass, and many successful experiments are related. A grapery, rooted in with blue and plain glass in juxtaposition, produced in a shorter time than usual bunches of extraordinary magnitude and grapes of unusual size. A litter of pigs was separated into two parties; the heaviest and best-conditioned were put in an ordinary pen, while the smallest and lightest were placed under blue glass through which came the solar ray. After several months it was found that the last named were far in advance of the pigs heavier to begin with, but reared in the usual piggery. A bull-calf, so puny and feeble at birth that small hopes were entertained for its survival, was placed under blue glass. In twenty-four hours it rose to its feet, walked about the pen, and was able to take some food. It began to grow and its development was marvellous. By the same means a mule that had been deaf for ten years regained its hearing, while a canary that had lost its vocal powers had them restored. Proofs were given that quadrupeds could be developed in twelve months, which under ordinary conditions required five years. Blue light then entered human therapeutics, running a rapid but brief course. It soon retired to the modest function of helping the growth of cucumbers, and toning down the brilliancy of solar rays in asthenopia.

The Chicago Department of Health found during the month of January 188 cases of small-pox. One hundred and eighty-two of these were removed to the small-pox hospital. Sixty-three were discharged from the hospital well, leaving 112 in the hospital. There were twenty-nine deaths, seven of which died outside of the hospital. Some were dead when first discovered, others so near death that they were not moved to the hospital. All those who died outside of the hospital had hemorrhagic small-pox, and were sick but a few days. None of them had been vaccinated, and all confluent cases had not been vaccinated. Some of the fatal cases had been vaccinated in infancy.

An Office Building for Physicians.—A correspondent of this city writes: If a large building were to be erected and devoted exclusively to physicians' offices, it would net a good income for the owner. It would not be an experiment, as the Columbus Memorial Building in Chicago is said to yield a clear profit of fourteen per cent. annually. The building should be near the Academy of Medicine, so that the library there would be an attraction. The owner would have to adopt a plan for admitting desirable tenants only. Offices should rent for prices ranging between five hundred and two thousand dollars per annum each. Imagine a handsome building extending from No. 18 to No. 28 West Forty-third Street, and extending through to Forty second Street. It is then easy to imagine this building filled with physicians who are weary of the changes of location that are necessitated by changes in real estate, which affect the physician who rents a house or part of a house.

World's Fair Psychoses.—A considerable number of cases of insanity have been observed by medical men, occurring in persons who have made pilgrimages to the World's Fair and have become exhausted by sight-seeing and the excitements of Chicago and the late Midway.

Reviews and Notices of Books.

Clinical Gynecology. Being a Handbook of Diseases Peculiar to Women. By Thomas More Madden, M.D., F.R.C.S., Ed., Obstetric Physician and Gynecologist, Mater Misericordiæ Hospital, Dublin, etc. With 259 illustrations, pp. xvi.–562. Philadelphia: J. B. Lippincott Co. 1893.

This readable volume consists of a series of clinical lectures, covering the same ground as Goodell's well-known work, though its general tone is less surgical than the latter. Being intended, as the author states in his preface, largely for his immediate circle of pupils, it is naturally strongly local in its coloring, and contains many descriptions of instruments and methods of treatment which may seem curiously antiquated to the progressive gynecologist.

For example, in the chapter on the perineum there is apparently no recognition of the well-recognized anatomical fact that the perineum forms only a small part of the pelvic floor, and is not the "natural *point d'appui* of the vaginal column." We thought that Baker Brown's operation had long been forgotten, but the familiar illustration of the older text-books is still retained. Tait's flap splitting method is regarded as the ideal modern improvement, and there is practically no recognition of the operations of the German school.

In the description of Emmet's operation for repair of the lacerated cervix the author follows closely its originator, but the after-treatment—the use of tampons and daily douches, and early removal of the sutures—is not in accord with modern practice. The chapters on malignant disease of the uterus are quite exhaustive, which cannot be said of those on fibroids. A curious relic of former pathology appears in the shape of a paragraph on "corroding ulcer," as a distinct affection. The chapters on displacement show the influence of the pathological theories of a former generation, especially in regard to replacement of the anteflexed uterus on the sound (!) and the retention of the old-fashioned cradle pessary, which has become a veritable curiosity in this country. The operative treatment of retroflexion, whether by shortening the round ligaments or by hysterorrhaphy, is regarded as unjustifiable, the author's condemnation being also applied to all but the simpler plastic operations for the cure of procidentia. His conservative attitude toward the removal of the adnexa is somewhat offset by his readiness to resort to conservative treatment even in well-recognized cases of pyosalpinx. It is desirable that the expression "chronic oöphoritis" should be banished from modern text-books, since it is entirely misleading. In the sections on the treatment of this condition there is no reference to the beneficent action of electricity, which here finds its most valuable application in gynecology. Between blisters and bromides and oöphorectomy there certainly remain some palliative measures which should at least be mentioned. The description of ovariotomy is clear and practical, though rather brief, the numerous accidents and complications being passed over. Following the almost invariable, but none the less reprehensible, practice, the author devotes a separate division of the book to menstruation and its disorders, instead of treating them simply as symptoms of affections previously described.

The concluding chapters are of a miscellaneous character, such as spurious pregnancy (one of the most interesting and practical in the book), hæmatocele, the disorders of pregnancy, and ectopic gestation.

The author's style, though colloquial, is clear and forcible. His lectures are the result of personal experience, and if to surgical readers he may at times appear to be ultra-conservative, he is certainly a safe guide for the student, who is only too apt to turn from the tedious details of palliative treatment to the attractive demonstration of a new operation, which too often promises more than it performs. We have criticised this handbook rather from a scientific standpoint, since personally we entertain a high respect for the school of gynecologists of which the author has ever been a consistent member.

Chirurgie des Voies Urinaires. Étude Clinique. Par le Dr. E. Loumeau. 8vo, pp. 300. Bordeaux: Feret et Fils. 1894.

The excellent work done in genito-urinary surgery by the French surgeons will accord to this volume the reception it deserves. As its title indicates, it is a collection of well-written clinical cases which cover the entire field of this branch of the surgical art. The simpler conditions, such as phimosis, gonorrhœa, and cystitis are no less carefully considered than are perinephritic abscess, foreign bodies in the bladder, urethral stricture, and the operations for stone. The work is written purely from the clinical standpoint, and contains many valuable suggestions derived from the author's experience.

Anatomy, Descriptive and Surgical. By Henry Gray, F.R.S., Fellow of the College of Surgeons, Lecturer on Anatomy at St. George's Hospital Medical School. Edited by T. Pickering Pick, Surgeon to and Lecturer on Surgery, St. George's Hospital, etc. 8vo, pp. 1129. Philadelphia: Lea Brothers & Co. 1893.

From the time this work first appeared, in 1857, it has been considered the standard one on its subject. Since that period it has triumphantly passed through thirteen editions, and the last now before us revives the old love for the book which we entertained during our student days. Few treatises can claim such a record of endurance of usefulness for a period of thirty-six years. To say that it still maintains its reputation is to give it the highest compliment within the range of the critic's privilege. It has grown and strengthened with the advancements and requirements of the modern knowledge of anatomy, enlarging its scope for newer adaptations in surgery and physiology; the numerous cuts have been increased and elaborated, and colors have been added to aid in further elucidation.

Index Catalogue of the Surgeon-General's Office, United States Army. Vol. XIV. 4to, pp. 1016. Washington, Government Printing Office. 1893.

This volume, from Sutures to Universally, includes references to 10,124 author titles, representing 6,426 volumes, and 8,850 pamphlets. It also includes 9,867 subject titles of separate books and pamphlets, and 38,461 titles of articles in periodicals. It is still under the able editorship of J. S. Billings, Surgeon, United States Army.

Selected Papers in Gynecology and Obstetrics. By D. Berry Hart, M.D., F.R.C.P.Eng., etc., late President Edinburgh Obstetrical Society. Edinburgh and London: W. & A. K. Johnston. 1893.

This is a reprint of papers previously published in various journals, chiefly in the *Edinburgh Medical Journal*. The author is well known as an active and original worker in this special field, and the present collection of papers will be perused with interest by gynecologists and obstetricians.

Les Kolas Africains, Monographie botanique, chimique, thérapeutique et pharmacologique. Par M. le Dr. Édouard Heckel, professeur à la Faculté des Sciences et à l'École de Médecine de Marseille, correspondant de l'Académie de Médecine, lauréat de l'Institut. Paris: Société d'Éditions Scientifiques. 1893.

This is, as far as we know, the first exhaustive treatise upon the kola nut and its use in medicine. The work is a most elaborate one, consisting of four hundred octavo pages and illustrated with some fifty woodcuts and a colored plate. It treats of the botany, chemistry, therapeutics, and pharmacology of this drug in a way that leaves little to be done by future investigators.

Society Reports.

LONDON CLINICAL SOCIETY.

Paraplegia after Typhoid Fever.—Dr. Mott showed a patient who eight years previously had an attack of typhoid fever which lasted three months. After the attack the patient was unable to stand or walk. There was exaggerated reflexes, both superficial and deep, and ankle clonus. There was no loss of sensation. The sphincters were but slightly affected, though there was some difficulty in retaining the urine. Dr. Mott thought that the lesion was a focal myelitis, a transverse lesion, perhaps spreading from a patch of meningitis.

Nephrectomy for Malignant Tumor.—Mr. Malcolm gave the details of a nephrectomy in a child two years of age. The tumor had been noticed for about a year. It filled the entire right loin, and to the touch was elastic, oval, well defined, painless, and scarcely movable. The child was anæmic, moderately strong, and no changes were apparent in the urine. The abdomen was opened in the median line and the tumor was removed through an incision in the posterior layer of the peritoneum, immediately to the outer side of the ascending colon. The tumor was of oval shape, six inches long and four inches wide. It was of an adenomatous nature and involved only the anterior portion of the kidney, the posterior half being apparently normal. The child made an uneventful recovery, and a year later was quite well. The tumor was separated from the kidney by a capsule of dense fibroid tissue, and consisted of tubes lined by epithelial cells with a scanty and exceedingly delicate stroma, but with strands of connective tissue dividing the field into large loculi.

Mr. Malcolm further stated that, contrary to the opinion recently advanced by Bland Sutton, he could not consider the growth as a connective-tissue neoplasm.

OPHTHALMOLOGICAL SOCIETY (LONDON).

School Ophthalmia.—Mr. Hutchinson spoke of the frequency of occurrence of this disease, particularly in the lower-class schools. In some schools as many as fifty per cent. were affected. It occurs under conditions where no gross hygienic faults can be found, spreads from the sick to the healthy, and resists treatment. A papillary condition of the conjunctiva quickly develops, there being but a few instances of true sago grains. The diagnosis of early and slight cases is difficult, and it is therefore advisable to treat all doubtful cases. It appears to spread especially in bed-rooms, and particularly between individuals occupying the same bed. It appears as though a specific contagium conveyed the disease from patient to patient. Sporadic cases were very rare and were met with very infrequently in private practice. It seemed probable that Egyptian, military, and school ophthalmia were identical. The treatment required is isolation and the application of mercuric chloride or silver nitrate.

ACADEMY OF MEDICINE (PARIS).

The Surgical Treatment of Goitre by Esothyropexia.—By the above name Dr. Poncet, of Lyons, proposes to designate a new method of treating goitre by operation. It consists, after first having made an incision in the median line, of drawing forward and fixing a more or less considerable part of the goitre, which after a variable time atrophies. The method has the advantage of complete innocuity and absence of hemorrhage. It is simple, rapid, and especially indicated in goitre complicated with attacks of suffocation. He has applied it with success in fourteen cases. The atrophy of the goitre follows in from four to six weeks. After esothyropexia in exophthalmic goitre the general phenomena of this disease tend to disappear, and in certain cases where mental symptoms have been manifest the intellectual functions revive after a longer or shorter time.

SOCIETY OF PHYSICIANS AND SURGEONS (PARIS).

Surgical Treatment of Post-operative Peritonitis.—Dr. Nitot made some observations *apropos* of the surgical treatment of post-operative peritonitis. He emphasized the necessity of reopening the abdomen, making an abundant lavage, and then establishing drainage in the inferior portion of the abdominal cavity. This last procedure is, he believes, quite essential.

A Case of Tetanus.—Dr. Reynier detailed a case of traumatic tetanus occurring in a boy seven days after an injury of the hand. In spite of continual irrigation of the wound with sublimate solution, tetanus supervened. The forearm was amputated at the first appearance of the tetanus and an injection of antitoxin administered. Then chloral hydrate was administered in large doses, but the patient died in a tetanic crisis shortly after. He remarked that although the amputation prevented the microbes from entering the circulation, it did not do the same for the toxines manufactured by the germs and which caused the tetanic crisis.

SOCIETY OF PHYSICIANS (VIENNA).

The Operative Treatment of Tumors of the Bladder.—Dr. Frisch believes that the best information concerning the position, the diagnosis, and operativity of tumors of the bladder can be obtained by the cystoscope. Benign tumors, even when they are multiple, and have their seat in the lower portion of the bladder and around the opening of the ureters, are operable and the prognosis is good. There are also forms of carcinoma in which the infiltration is limited to the walls of the bladder, that are operable. Naturally all operative measures are of the nature of resection, perhaps eventually total extirpation of the bladder. The prognosis in all forms of carcinoma of the bladder is doubtful. The wholly inoperable are those in which there is not alone infiltration of the bladder-wall but the tissues around the bladder. He believes that the chances for recovery in operations on the bladder for carcinoma are becoming more favorable every year.

ROYAL SOCIETY OF PHYSICIANS (BUDAPESTH).

Blood Changes in Syphilis.—Dr. Justus stated the results of his studies of the blood in one hundred patients suffering from syphilis. When syphilis is not influenced by treatment the amount of hæmoglobin diminishes in proportion with the severity of the symptoms, and when the syphilitic developments recede the hæmoglobin increases. The diminution of hæmoglobin is often apparent in one day when the secondary manifestations of syphilis are active. When a patient is treated with hypodermatic intra-muscular injections of mercury the injection is followed by a rapid diminution of hæmoglobin, which, however, in the course of a day returns to normal. A second injection is followed by a second shrinkage of the hæmoglobin. After a few injections a time comes when the injections are followed by no lessening of the hæmoglobin, but, on the contrary, an increase is manifest, and a continuance of the injections from this time on is accompanied by an increase. When the patients are treated by inunctions, the hæmoglobin falls after the first inunction, but gradually, after a few days, it increases until it becomes greater than it was originally before the treatment. Recovery is simultaneous with the appearance of the increase in hæmoglobin, therefore this becomes a diagnostic and prognostic sign of great importance.

Cancrum Oris.—Place cotton so as to prevent spread of acid, and apply nitric acid after cleansing with peroxide of hydrogen and spreading vaseline over surrounding parts. Judicious stimulation. Bichloride, moist dressing (1 to 4,000) constantly applied.—Abbe.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 15, 1894.

D. B. St. John Roosa, M.D., President, in the Chair.

The meeting was held under the auspices of the Section on Pediatrics, the Chairman of which, Dr. Joseph E. Winters, occupied a seat on the platform.

Scurvy in Children.—Dr. W. P. Northrup opened the discussion upon this subject with a paper. The first case which he had ever seen of scurvy in a child ended fatally, for the reason that he was unfamiliar with the disease. It had only recently been brought to the attention of pediatrists in Europe, and the first article upon the subject, presented at the International Medical Congress at Copenhagen, had not yet reached him through the Transactions. The history of this case, seen at the New York Foundling Asylum in 1889, was given by him, together with the autopsy, in a paper read before a meeting of the American Pediatric Society. While the attention of pediatrists had thus been called to the occurrence of scurvy in children, it was desirable that it should be more generally known to the profession. Without a correct diagnosis and appropriate treatment, the disease was very fatal. On the other hand, when recognized it was very amenable to simple measures.

Two years after seeing his first case Dr. Northrup saw another typical one in consultation in a child of sixteen months, of well-to-do parents, who had fed it exclusively for eleven months on a proprietary food. It seemed to flourish until sixteen months of age, when the nurse noticed some trouble with the gums; then the child complained of pain on handling and kept the right lower limb nearly straight. It was treated for rheumatism. Dr. Northrup found no difficulty, after his previous experience, in making the diagnosis of scurvy. The gums were ragged and swollen, the right lower limb presented a fusiform swelling, largest below the knee, which gave rise to great anxiety on the part of the patient lest it should be moved, and caused pain. These were the only external signs. The diet was changed to cow's milk, beef juice, and orange. The latter was taken with avidity. The recovery was rapid.

Recently a German observer had discovered a bacillus to which he attributed scurvy, but his observation required confirmation from others. An analysis of the cases already reported in this country was given, and in summarizing his paper, the author defined scurvy as a condition of malnutrition which affected the capillaries and allowed the blood to escape from the vessels, leading to what might be called hemorrhagic gingivitis and to hemorrhagic petechiæ or ecchymoses of the skin in some cases, to hemorrhages from the mucous membranes, but more especially to collections of blood about the femora and beneath their periosteum. There was also anæmia. Tenderness was a prominent symptom about the swollen limbs. Most of the cases had been attributed to persistent feeding with prepared foods and condensed milk. The disease was most typical during the second year of life, when the teeth were present with their swollen and ragged gums. The treatment consisted in a change of diet, orange, and other fresh fruit. Scurvy was supposed to be a distinct entity, although frequently associated with or superadded to rickets, formerly called acute rickets.

Scorbutic Pseudo-paralysis. — Dr. Henry Lyng Taylor continued the discussion. He had chosen this title for his paper in order to emphasize a peculiar and prominent symptom frequently present in cases of infantile scurvy. His case had been referred to in Dr. Northrup's paper, and had been treated for supposed spinal disease or hip disease. It was that of a girl of eleven months, brought to him from the South last August. The child had been fed exclusively on a special brand of condensed milk, had seemed to thrive on it up to the age of six or seven months, when the parents noticed that she could not sit up as she had done before, that she had a peculiarly bent attitude, indisposition or inability to use the legs, and later the trunk. There was a tender swelling on the right thigh which disappeared in a few weeks; spongy and bleeding gums; slight rash over the entire body; swelling about one eye which disappeared in a week or two, leaving a purplish stain; a few purplish spots on the skin which did not last long; swelling above the right ankle. During the development of these symptoms the nutrition became much impaired, the baby lost flesh and appetite, slept badly, became peevish, and excessively sensitive to the slightest touch or movement. There was later profuse perspiration, especially of the head. No disturbance of the stomach or bowels, although poor appetite. Rectal temperature, 102.5° F. The skin was dusky, covered with a papular eruption, face anxious, indicating severe and continued suffering; the breath fetid. The child lay in a bent attitude, the legs somewhat flexed, no attempt being made to move them. There was, however, motion at the joints, the toes and ankles moved, the knee reflex was normal, there was moderate swelling above the right ankle, the baby moved the arms and head naturally. The spine was abnormally rigid and somewhat bent, and there was a projection at the first and second lumbar vertebræ. Photographs were exhibited showing these points, and the progressive change to the normal attitude as treatment was carried out. There were no symptoms of rickets. The clinical picture was typical of scurvy, and he was able to make the diagnosis from having read Dr. Northrup's paper. Dr. J. H. Fruitknight saw the patient with him. The baby was at once put on a diet of cow's milk, raw meat juice, and orange. The juice of the orange was sucked greedily. No drugs except a laxative. The first night after the change the patient slept soundly; the eruption soon faded, the fever went down, the gums healed, the legs regained their usefulness, the swelling subsided, the patient soon sat up, and the parents returned with her home, where she had since remained well.

The parents of this patient told him a neighbor's baby had been fed on the same brand of condensed milk, had suffered in a like way after about the eleventh month, and two months later died.

After again reviewing the symptoms of pseudo-paralysis in his case, which was common in the lower extremities in the scurvy of children, Dr. Taylor considered the explanation of the phenomenon. Was it due to the bloody and serous infiltration of the muscles and periosteum, giving rise to pain on motion; or was it malnutrition of the nerve-centres, or impoverishment of the blood-texture? The pseudo-paralysis was easily distinguished from other infantile paralytic affections. Scorbutus might exist with rickets or be mistaken for it, and it was well, therefore, to examine the gums when a case of rickets presented itself. There was no local elevation of the temperature in the limb, as there was in rheumatism and inflammations.

Letters were read by Dr. Crandall from Drs. T. M. Rotch, of Boston; Louis Starr, of Philadelphia; A. D. Blackader, of Montreal; F. Forchheimer, of Cincinnati; and others, giving their experience with scurvy in children.

After citing cases, Dr. Starr said regulation of the diet was the main point in treatment. Condensed milk and farinaceous baby foods must be absolutely forbidden. The milk might be sterilized, if it were thought advisable, but not at a high temperature. He had also given orange juice and raw meat juice daily.

Dr. Rotch said in his letter that Dr. Northrup had been first to describe scurvy in children in this country. He had himself seen some cases of scurvy in children earlier in his practice, but had failed to recognize them. Of recent years he had seen about twenty cases. He had also seen scurvy rapidly recover under orange juice, while rickets, which was also present, pursued its usual slow course.

Dr. Forchheimer wrote that in one of his cases the peculiar complexion lasted eighteen months after recovery from the scurvy, although the anæmia had practically

disappeared. According to our present knowledge, he thought the disease was probably due to some chemical change in the blood, one which could be corrected by fruit juice and change of food. The most acceptable treatment had been orange juice, lemon juice, and cow's milk. He referred twice to the aid to be derived from treatment in making a diagnosis in cases at all doubtful. He had seen ten cases.

Dr. Lockwood, of Baltimore, wrote that he had seen no new cases since the one referred to in Dr. Northrup's former paper, and Dr. Hooker had seen none which had not already been reported, although he had been on the lookout for cases.

Dr. J. Lewis Smith said that during the many years he had been connected with the Out-door Department of Bellevue Hospital scurvy in children was seen very rarely, whereas rickets was very common. Physicians, however, might overlook scurvy when it developed prior to the appearance of the teeth, since at that age there would not be the important symptom of spongy gums. He did not believe that nursing babies up to the thirteenth month had the disease. Of course scorbutus was not a new affection, as its presence in seamen had been written about at least two or three hundred years ago. In typical cases of rickets there was apt to be great multiplication of the capillaries under the periosteum, with thickening of this membrane, which might be mistaken for the swelling due to effusion of blood in scurvy, unless, if the case reached the autopsy table, a microscopic examination were made.

Dr. A. Jacobi had seen a large number of cases of scurvy in children since Dr. Northrup first called attention to it, had seen a small number before, and probably had overlooked many more. The majority of the cases occurred during the winter. The first half of March, 1892, he saw three cases. He had not seen a case where the child received normal food; nearly all were artificially fed. Quite a number were fed exclusively on sterilized milk. He had always regarded sterilized milk as an abomination when used as an exclusive diet. While absence of teeth in young babies and old people might make the diagnosis less easy, yet he had seen scurvy in one baby of four months, in one of six months, and in a third of six weeks; and while two of them had not spongy gums, one, the baby six months old, but without teeth, did have spongy gums. Dr. Jacobi said it was still a question whether scurvy was an entity, or whether it was related to other hemorrhagic affections. No matter, however, what might be the condition of the blood, it would not give rise to hemorrhages unless there was disease of the blood-vessels.

What diagnosis did we formerly make when we did not recognize scurvy? Many years ago he had diagnosed acute rickets, but now he could conceive that many times he had been mistaken. This very winter he had seen cases of scurvy in which the physician had treated the patient for rheumatism. Twenty or thirty years ago, however, acute rheumatism in children was hardly acknowledged to exist. Ulcerative gingivitis should never be mistaken for scurvy. In treatment he had given fruit juice with good results, had insisted upon animal food; he seldom if ever permitted babies to be fed on pure cow's milk, but always added some cereals. He would also give phosphorus in substance, say ten to fifteen minims in oil three times a day, of the preparation of the Pharmacopœia, containing a grain to the hundred minims. In one case seen by him there was a suspicion that diarrhœa was the cause of the scurvy. If a bacillus was the primary factor, this case might suggest that it was the bacillus coli commune. The baby died speedily. It appeared that no healthy baby would ever take scurvy, just as none would take diphtheria. A number of the patients seen by him had had some disease of the respiratory passages, especially bronchitis.

Dr. L. Emmet Holt discussed the question whether sterilized milk would cause scurvy. The question had been raised in London, and the physicians there seemed generally to believe that sterilized milk was a potent factor. Yet in three institutions in New York City where there were large numbers of children, it had been the custom for perhaps five years to sterilize all milk, yet only one case of scurvy had occurred in the three institutions during that time. In one case the infant had been fed entirely upon malted milk, at Dr. Holt's own direction, because it was the only food which corrected constipation and trouble from which the child had been suffering. He had seen four cases of scurvy the past year, all occurring during the summer. One of the worst cases he had ever seen was in a baby which had been fed exclusively on a widely advertised proprietary food. In one case a swelling of the knee had led the doctor to diagnose sarcoma. In five of the six cases seen by him, the scurvy had developed from the exclusive use of the proprietary food referred to above. Most of his cases showed a marked degree of cachexia, but at least two did not. All had occurred in private practice. All but one in the country where fresh milk should be easy to obtain, but was not used; for it seemed that in the country prepared foods were employed more than in the city.

Dr. W. L. Carr said there was no doubt but what scurvy was a rare affection in New York institutions. There had been but one case out of over two thousand patients at Bellevue Out door Department, none at St. Mary's among a thousand patients seen the past year. Dr. Carr had seen three cases in private practice, and named another reported to him by Dr. Hardy. In one of the worst there was no gingivitis, but, like in two others, there had been diarrhœa. The symptoms rapidly disappeared under dietetic treatment. In this case there was also swelling of the forearms, but much less than of the lower extremities. It was rather peculiar that the hemorrhages were greatest where there was most active epiphyseal growth (lower end of the femur).

Dr. W. H. Fruitknight had seen five cases of scurvy since Dr. Northrup had read his first paper. At the St. John's Hospital, where sterilized milk was used, there had been but one case, and that had developed outside. As to relative significance of symptoms, the most reliable one when present was spongy gums. Under treatment this disappeared first, the swelling of the limbs last.

Regarding Etiology.—Dr. Max Einhorn mentioned, as suggestive of the causation, some experiments which he had made nine years ago with Ehrlich, bearing on diabetes. They put frogs in water containing bicarbonate of soda, and found at the end of fifteen or twenty days red discoloration of the fluid, which was proved to be due to red blood-corpuscles, not simply hæmoglobin. Dr. Einhorn was disposed to think that in scurvy there was a chemical change in the blood, perhaps relating to its alkalinity or the presence of an abundance of sodium.

Dr. Seabury Jones inquired of the speakers whether they regarded the prepared foods referred to as positive factors in the production of scurvy, or whether this was due to lack of other elements.

Dr. Holt remarked that one of his cases was almost like an experiment in natural science, for the infant had been fed exclusively on a certain prepared food, got scurvy, this food was stopped, the patient immediately improved, and went on to recovery.

Dr. Joseph E. Winters referred to a case seen last summer, in which the infant had been fed exclusively on the same prepared food referred to by several speakers during the evening, and recovery was prompt after no other change than to sterilized cow's milk. The only treatment which it was his custom to employ was sterilized milk. He did not believe sterilized milk ever caused scurvy, if it were done right. The sterilizing process should never continue longer than twenty minutes.

Dr. Northrup added the cases of scurvy reported this evening to those reported previously in this country, and found the number to be seventy-two, exclusive of Dr. Jacobi's, who had not stated just how many he had seen. He agreed with Dr. Holt and Dr. Winters, that sterilized milk did not cause scurvy. The large experience with it

in the feeding of infants at the New York Foundling Asylum, Infant Asylum, and other institutions, proved that. On the other hand, proprietary foods were almost universally the cause, especially the one which had been most widely advertised, namely, Mellin's food.

The President called attention to the fact that the bureau of nurses was in operation, and it was hoped the profession would make it self sustaining and even a source of income to the Academy. Attention was also again called to the smoking and grill room.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, January 25, 1894.

Herman J. Boldt, M.D., Chairman.

Election of Officers.—There being but one nominee for each of the two offices, the secretary was instructed to cast an affirmative ballot for Dr. Malcolm McLean as chairman, and Dr. George W. Jarman as secretary of the section for the ensuing year.

Home made Incubator.—Dr. Marx exhibited an inexpensive incubator for the prematurely born but viable child. It comprised two compartments, one for the babe, the other for the heating apparatus. In the latter was an alcohol generator and a coil of pipe for steam.

Umbilical Hernia.—The Chairman, Dr. Boldt, presented, in accordance with a promise made at the last meeting, one of six patients whom he had operated upon and cured of umbilical hernia by taking out the entire sac wall, freshening the edges of the muscles and bringing all the wall structures from the two opposite sides together with a single layer of wire suture. The women weighed from 185 to over 200 pounds each. Had been operated upon over two years ago, and there had been no return of the hernia.

Premature Atrophy of the Genitalia.—Dr. Vineberg related the case of a woman whom he had expected to present in illustration of premature atrophy of the genital organs. She was twenty-five years of age, had been married four years, was well formed, had menstruated at the age of fifteen and continued to do so regularly until about eighteen months ago. Since then she had menstruated only once every three or four months. The uterus was now of the size of an almond, the appendages could not be made out because of the thickness of the abdominal walls, the vagina and external genitals were atrophied, presenting the appearance of those of a woman past fifty. There were no special symptoms other than those usually pertaining to the menopause.

Small Cystic Degeneration of the Ovary.—Dr. Francis Foerster read the paper. The term small cystic degeneration of the ovary was to most of us an obsolete one. A few years ago, however, it was met with frequently. Having given the subject some study, Dr. Foerster summed up his conclusions as follows: 1. Small cysts are common, not only in the ovaries of women, but also in those of the sow, ewe, and cow. 2. I am convinced that the small cysts are originally Graafian follicles. 3. In a process, not exactly pathological, the stratified epithelial lining of the Graafian follicle undergoes peculiar changes leading to its disappearance. 4. The epithelium first breaks up into an indifferent or embryonal condition and from this arises myxomatous tissue. 5. The type of newly formed or myxomatous tissue varies in different animals; it may be medullary, myxomatous, or fully developed myxomatous tissue with very well marked basic substance. 6. The newly formed myxomatous tissue is always scantily supplied with blood-vessels, which probably go into it from without. 7. The myxomatous lining of the cyst-wall is always well defined from the outer fibrous coat, the original corpuscle of the Graafian follicle. 8. The ovule is present at the beginning of the small cyst, but later it disappears, owing to changes of environment.

What are the Indications for a Vaginal Examination?—Dr. E. B. Cragin read the paper (see p. 266).

Steer Clear of Extremes in Medicine.—Dr. Malcolm McLean thought one of the greatest difficulties encountered by the practitioner was to steer clear of extremes in medicine. It was one extreme to rush into the physical examination of every woman simply because she complained of certain local pains or disturbance. The opposite extreme was to neglect examination on sentimental grounds. He thought the author had made these facts very clear, and he hoped they would be heeded.

Advises Examination Three Months After Confinement.—Dr. Vineberg thought all women should be examined two or three months after confinement, a practice which had been neglected even by specialists in obstetrics. Most physicians satisfied themselves with an examination the second or third week, and while that was good practice as far as it went, he thought the later examination might explain symptoms which did not manifest themselves at the earlier date. It was very common for women visiting a gynecologist to say their symptoms began only some weeks after confinement.

Change of View with Wider Experience.—Dr. A. F. Currier thought it difficult to lay down rules for guidance in the examination of young unmarried women. Some time ago he had thought there were very few girls in whom a vaginal examination was justifiable, but further experience had convinced him that the field for such work was larger than he had supposed. A good many young women came to us who were anæmic, flabby, suffering much from menstrual troubles, in whom we perhaps neglected to examine the pelvic organs; their condition did not improve, we were finally forced to make an examination, and frequently found, if not a condition of acute or pretty general inflammation of the pelvic organs, at least a condition of displacement which might ultimately result in such inflammation. He referred to such a case in which examination revealed acute retroflexion.

Regarding the second class of cases, he would not wait until the woman had passed through the puerperium before making an examination of the pelvic organs to learn their condition. It was better to start at the root of the trouble and ascertain positively just after labor what condition the organs were in. If a very decided fissure of the cervix were found, then was the time to close it and thus anticipate trouble which might have come afterward. The statements with regard to indications for examination at the change of life were also sound.

Immediate Repair of Injuries After Confinement.—Dr. R. W. Murray was glad to see that the practice which had long been advocated before the New York Obstetrical Society was giving indications of becoming general among the profession. He had more especially in mind the immediate repair of injuries after confinement, which he was one of the first to advocate. If this were done it would hardly be necessary to examine the patient two or three months after labor. Regarding the examination of unmarried women, the same indications applied as in the case of married women, leaving out lesions distinctly due to the marital relation. It were better to first make a rectal examination, as it would cause the unmarried woman less shock than a vaginal examination.

The Chairman thought the trouble was not always in neglecting to make an examination when it was indicated, but that often there was failure to discover or to properly treat the condition present. He had within a week seen a patient who had cancer of the uterus too far advanced to permit of hysterectomy, yet she had not long before been examined by a doctor who discovered nothing and attributed all the symptoms to the change of life. In another case a pessary had been introduced for which there was actually no indication.

Dr. Cragin made some closing remarks. He would not advise the general practitioner to sew up the lacerated cervix at once. Having had no experience, he was liable to draw the sutures too tightly and to cause sepsis. The specialist, however, could operate at once.

SECTION ON GENERAL MEDICINE.

Stated Meeting, January 16, 1894.

CHARLES E. QUIMBY, M.D., CHAIRMAN.

Value of the Hæmatokrit in the Diagnosis of Anæmia.—DR. JUDSON DALAND, of Philadelphia, read the paper. The hæmatokrit was an instrument intended to take the place of the hæmacytometer. The difficulties and uncertainties in estimating the number of blood corpuscles by the latter instrument had led him to seek a substitute. One who used the hæmacytometer much found himself suffering from eye-strain and nervousness and had not full confidence after finishing his work that the result was entirely reliable. The blood might not be diluted just enough, the corpuscles might not be uniformly distributed throughout the fluid, they might not be equally distributed over the field. Comparing the results of his own counting with those of another who had had much experience in the use of the hæmacytometer, there was a difference in their count in the first case of 1,043,000 red corpuscles to the cubic millimetre, and of 350,000 when they used the same dilution. The same observer would frequently find a difference in his counting of over 50,000 corpuscles to the cubic millimetre in the same patient.

Dr. Daland had already published one modification of the hæmatokrit, and to night presented a further improvement. It consisted of a machine for applying centrifugal force in separating the red blood corpuscles at one end of a tube from the rest of the fluid. A framework inclosed a series of wheels by which very rapid rotation was secured of a spindle which projected outside the casing, and it was on this spindle that the small graduated glass-tube was placed, containing the blood. By moderate rotation eight or nine thousand revolutions were obtained a minute. The instrument as first designed was thirty-five millimetres long, one millimetre in diameter, and was divided by markings into fifty parts. The blood was first diluted with a solution of bichromate of potash, was picked up with a pipette from a watch-glass, and, although the results obtained by this process could be called accurate, yet there was liability to error from the difficulty of measuring the blood accurately, from rapid evaporation, from admixture of air bubbles, from tendency of the red corpuscles to gravitate as soon as the mixture was made, the multiplication of the error, should one take place, by four, because of the dilution of the fluid with the bichromate of potash solution and of the division of the tube. These objections had been overcome in a later instrument, the scale on the tube being increased to one hundred, and the blood being taken directly from the finger, so that there was no dilution made, no chance for admixture of air, no danger of taking up more than the normal proportion of corpuscles. The revolutions were begun at once. The result of the rotation was that the blood corpuscles settled at one end of the tube, and it had been found that their volume was in proportion to their number in a cubic millimetre of blood. The average of forty-five examinations gave 5,100,000 to the cubic millimetre. The instrument also showed the percentage of white corpuscles where these were not greatly below the normal proportion.

Dr. Daland said, in conclusion, that this form of centrifugal machine might also be used for rotating serum, milk, and other fluids.

DR. W. GILMAN THOMPSON had been more favorably impressed with the instrument presented than he had been when he had first heard of it; yet he thought it would not replace a microscopic examination in anæmia when accuracy was important. He thought one of the chief advantages of the hæmatokrit lay in the fact that it enabled one while estimating the number of red corpuscles to also judge of their proportion to the white corpuscles. The question suggested itself, Would there not be too much destruction of the red corpuscles during the rotary process? He thought it a valuable instrument, one destined to largely do away with the hæmacytometer.

DR. R. W. WILCOX hoped soon to have some practical experience with the instrument, for he believed it would prove an important practical aid in determining the red and white corpuscles.

DRS. SMITH, BYRON, JAMES E. KELLY, and DALAND continued the discussion. Dr Daland said that when the number of revolutions was only three or four thousand a minute the corpuscles were not thrown together so compactly. The instrument was intended to give a fixed standard, so that uniform compactness would be secured. After the revolutions the corpuscles had been examined and had been found uninjured. This was true, at least, in the first tests when bichromate of potassium had been used in dilution; in later experiments he was unable to speak on this point.

Officers Elected.—Dr. William H. Porter, *Chairman;* Dr. Le Boutillier, *Secretary*. The date of meetings was changed to the first Wednesday of each month.

Surgical Suggestions.

Horsehair, thoroughly cleansed and ready for use, is now kept by some instrument dealers. It never absorbs anything, is as impervious as glass, and can be rendered perfectly aseptic. It is valuable in all suturing of the skin.—LEWIS.

Silk-worm Gut makes an ideal suture. It is sterilized without any trouble by immersion in steam for three or four minutes.—STORER.

Carbuncle.—Inject equal parts of pure carbolic acid, alcohol, and glycerine.—WILKINSON.

Nephrectomy for hydronephrosis is not warranted unless the kidney substance is completely destroyed or the ureter is impervious.—GRAHAM.

Dermatol, by combining with the ptomaïnes produced by the growth of bacteria, forms compounds which are unfavorable to the development of the latter.—STONE.

Lipoma of the palm or other situation may be distinguished from a fluid collection by spraying ether over the part. In case of lipoma the fatty matter will become solidified by the cooling process.—POLAILLON.

Nævus.—Thread through the growth silk previously soaked in alcohol and perchloride of iron (Rosen's method). Left in a week, these threads close up all blood-vessels through which they pass.—ABBE.

Dilatation of the Stomach.—Draw out stomach through an incision parallel with border of left ribs. Make fold in organ large enough to reduce to normal size. Suture greater curvature nearly on line with lesser. The fold hangs within stomach, and organ can empty itself completely.—BIRCHER.

Cysts of Spermatic Cord may be spermatic. Extirpation is better than injection. Open sac at once rather than attempt enucleation. Apply pressure after operation, which must be strictly aseptic.—GROSS.

Hemorrhoids when prolapsed and inflamed and operation is refused, paint daily with tincture of iodine.
—IVANOFF.

Depilatory.—

℞.	Iodi pur.	gr. xij.
	Ol. terebinthinæ	℥ xx.
	Ol. ricini	f ʒ ss.
	Alcohol.	f ʒ ijss.
M.	Collodii.	f ʒ j.

Apply daily for three days.
—BUTTE.

Sponges.—The sponges are first steeped in a hydrochloric-acid solution, 1 to 10, then immersed in a bath composed of hyposulphite of soda, one part, hydrochloric acid, two parts, water, twelve parts. This solution is then pressed out, and the sponges are well washed in cold water. They are finally placed in a bath containing half an ounce of carbonate of potash.—MAYLAND.

Traumatic Tetanus.—Subcutaneous injection of antitoxin prepared from the serum of an immune dog (cultures of tetanus bacillus having been made from wound). One injection of twenty-five centigrams morning and evening.—Casal.

Malignant Tumors. On several occasions it could be seen that injections of methyl violet brought about a necrobiosis of the elements most deeply stained. It acts by thrombosis.—Nann.

Pyosalpinx.—Many cases of pyosalpinx are curable without mutilating operations if the endometritis be treated by curettage and drainage with strict antiseptic precautions.—Murray.

Joint Tuberculosis.—Parenchymatous and intra articular medication with anti-bacillary remedies has yielded the best results in tubercular spondylitis attended by abscess formation and tuberculosis of the knee and wrist-joints.—Senn.

Antiseptic Solution.—

Acid thymic	1
Alcohol at 90°	4
Aq. dest	995

Pruritus Hiemalis.—

℞.	Menthol	ʒ iiiss.
	Glycerin	f ʒ ij.
	Aquæ, ad	f ʒ iv.

M. Sig.: Apply.

—Corlett.

Irrigation of the deep urethra by catheter or tube is a rank failure, and generally does more harm than good.—Lydston.

Vaginal Hysterectomy.—It may be that a larger experience may modify my views, but at present it is my judgment that vaginal hysterectomy for the cure of aggravated prolapse is an unsatisfactory procedure, and that, as a rule, in such cases, abdominal hysterorrhaphy (hysteropexy) is a preferable operation.—McCosh.

Intestinal Anastomoses.—Thread a darning-needle with rubber cord, such as is used for the treatment of piles, then passing the needle through the long axis of two segments of bowel, a knot is tied, the knot itself being prevented from slipping by a ligature introduced into it, and tied over each turn of the knot. A series of Lembert stitches are usually inserted into the two segments of bowel outside the region of the ligature.—McGraw.

Ulcer of the Cornea.—

℞.	Aristol	gr. 1
	Atropine sulphate	centig. 0.05
	Vaseline	gr. 25

Size of pea under the lids.

Incarcerated Hernia.—Elevate pelvis—fex knees and thighs—support scrotal sac, every ten minutes or so pour over tumor and ring one or two tablespoonfuls of ether. When tension is diminished, spontaneous reduction occurs, or slight manipulation effects it.—Gussenbauer.

Strangulated Hernia.—Be thoroughly aseptic in herniotomy and divide the constricting bands freely, not with the probe-pointed knife cutting from within outward, but with the scalpel under the guidance of the eye from without inward—Gerster.

Curved Incisions through the skin should be made wherever possible. Healing is more rapid, the resulting scar is smaller, more room is given to work, suturing is easier, the resulting cicatrix is not over the seat of operation, diseased skin is avoided, etc.—Beale.

Club-foot.—Rectification and manipulation should be continued up to the age when the infant is ready to walk, at which time, if the foot cannot be placed upon the sole firmly, operative measures should be instituted.—Willard.

Golden Leal.—Twenty drops of fluid extract four times daily in vomiting of pregnancy.—Fedorow.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

CHELSEA HOSPITAL FOR WOMEN AND ITS SANITARY DEFECTS—UNUSUAL MORTALITY—PROPOSAL OF THE ROYAL COMMISSION ON THE UNIVERSITY QUESTION—SWAMPING OF THE MEDICAL DEPARTMENT—CLINICAL SOCIETY—ENDOSTEAL SARCOMA OF RADIUS—DEATH OF CRANSTOUN CHARLES, CARDEW, LILLROTH.

London, February 10, 1894.

The Chelsea Hospital for Women, an institution providing sixty beds, has been the scene of unusual mortality, and the medical officer of health for the district, after an investigation into its condition, has issued a report to his vestry recommending that notices be served on the governors requiring them to put the building into thorough sanitary repair within two months. The vestry has thereupon requested the Home Secretary to order an inquiry into the management of the hospital. The statistics of the past year certainly suffice to call for inquiry, but do not perhaps justify the charge of mismanagement nor the talk of "another hospital scandal" already heard. Subscribers to a charity are scarcely to be blamed for everything, although they may be called governors. Consulting officers are merely ornamental, or we might be astonished that such consultants as Robert Barnes, Spencer Wells, and Jonathan Hutchinson had not noticed the mortality of a hospital to which their names were attached—especially mortality of the description which has come to light. Six hundred and sixty in-patients were treated in 1893, the deaths being 36. Of these 21 were consequent on operations; 6 others were from septicæmia, of which 3 were after miscarriage. Of the deaths from operation, 2 were returned as septicæmia; 10, peritonitis; 2, shock, six and four days after operation respectively; and in 6 cases the actual cause of death is not stated. It is of course possible that further information may throw a different light on the figures, but whether this be so or not, the management must expect to be blamed, inasmuch as they did not at once supply every detail to the medical officer of health immediately he applied for them.

If your readers are not sick of the subject, I may report that another stage has been reached in the long agitated question of a teaching university of London. The royal commission on the draft charter of the proposed Gresham University reports in favor of so enlarging the scope of the present university of London as to meet the demands of all the educational bodies. The scheme propounded is likely to share the fate of other attempts to please all opposing parties. Thirty different interests are to elect sixty-six (!) senators. That fact alone will suffice to show how the subject bristles with difficulties. Contending interests of a most heterogenous character are to be pacified by a recognition of their educational position whenever they have persistently enforced their demands. In the new university there are to be six faculties—arts, science, medicine, law, theology, and music. In the senate, medicine will be completely overshadowed and outvoted, as it will only be able to master eleven votes of the sixty-six. And in this senate the crown, the government, the agricultural society, the civil engineers, the mechanical engineers, the trustees of the British Museum, the city corporation, and besides some others, the County Council, are to be represented. Surely this is the queerest academical Senate ever proposed. Perhaps the reaction that such a scheme for amalgamating opposing interests will produce, may lead us to entertain a more drastic method of compelling the existing university to do its duty. A little dictatorial instruction to it to prepare for reform is what is really needed.

In continuation of my notice of the last meeting of the Clinical Society, I must now report that Mr. H. Clutton related three cases of endosteal sarcoma of radius

1. A mycloid sarcoma of the head and neck of radius in a man aged twenty-eight, who had noticed a swelling for two years, already the victim of chronic kidney disease. The tumor was successfully removed by resection of the upper third of the radius. He died eighteen months after operation from kidney disease, but without any local evidence of a return of the new growth in the radius, and in the meantime his arm and hand were useful, and free from pain. 2. A painter, aged fifty-eight; for twelve months had pain and swelling in his left wrist. He had an endosteal growth of lower end of the radius, subsequently proved to be a mycloid sarcoma. It was treated by resection of the part affected. A corresponding portion of the ulna was removed at the same time to avoid any lateral deviation of the hand, which would otherwise have occurred. He has now (January, 1894) a very useful hand, and with a gauntlet can hold a pot of paint weighing nine pounds. 3. Was a round-celled sarcoma of the lower end of the left radius in a woman, aged thirty-four. The history of the case was of nine years duration, but the tumor was thought to be parosteal or periosteal, and was, therefore, removed by amputation. The specimen shows that it was an endosteal growth and might possibly have been successfully removed by resection without the loss of the hand. But considering its microscopical character, it is on the whole more satisfactory that amputation was performed. No return of disease.

Mr. Gould suggested that it was unnecessary to remove the bone beyond the seat of the disease, and he added that it might possibly suffice to open up the cavity and scrape thoroughly. He mentioned a case of sarcoma of the lower jaw in a young woman in which recovery took place after scraping, without recurrence for five years. And another in which he had excised for a large sarcoma in a man and there had been no recurrence for ten years.

Mr. Charles Symons mentioned the case of a girl, aged eleven, of a similar nature treated by scraping without recurrence since. Mr. Eve did not think the histological characters should be relied upon to show the degree of malignancy.

Mr. Bland Sutton pointed out that if the ulna were not shortened after resection of the radius, a useless hand would be left. Mr. Clutton, in reply, said that it was usually held that the longer the duration of the tumor, the longer would the patient probably live, whatever the treatment adopted. Mr. Malcolm related a case of nephrectomy (successful after fourteen months) for malignant tumor in a child, twenty-three months of age, of good family history, strong, and well-developed. She was said to have had a "full belly" when she was one year of age, and a definite "lump" in her side had been noticed six months later. This lump had steadily grown till it formed an elastic, oval, well-defined tumor, painless, and scarcely, if at all, movable. It filled the right loin extending well down toward the pelvis, and just beyond the middle line below the navel. The child was slightly anæmic, but her general health was good, and there was nothing abnormal in the urine. On November 15, 1892, the abdomen was opened through the right linear semilunaris, the kidney on the other side was examined and found apparently healthy, and the tumor was removed through an incision in the posterior layer of the peritoneum immediately to the outer side of the ascending colon which passed in front of the growth. The greatest care was taken not to open the capsule of the kidney which also included the tumor, but some of it was inadvertently separated during the enucleation of the deeper parts. When the growth was got out of the way, the remaining shreds of its capsule and a mass of glands and fat surrounding the right renal vessels were also carefully removed. The divided end of the ureter was brought outside the skin, and the wound was closed without drainage. During convalescence, the highest temperature and pulse, viz., 101° F., and 144 respectively, were recorded the day after operation. By the end of the week, fever was practically gone The wound healed well, and except the presence of a little albumin in the urine the first night, there was nothing of importance to record. A year later the urine was examined and nothing abnormal was detected in it. On January 25th, Dr. Marshall, of Barnes, reported that the child "is in perfect health," fourteen months after the operation. The tumor was of oval shape and measured six by four inches. The posterior half of the kidney substance was apparently healthy. The anterior half was partly replaced by, and partly expanded for a short distance over the new growth. The tumor was described by Mr. Targett as a "malignant adenoma," separated from the kidney by a capsule of dense fibroid tissue and consisting of tubes lined by epithelial cells with a scanty and exceedingly delicate stroma, but with strands of connective tissue dividing the field into large loculi. Examination of the gland by Mr. Targett, and Dr. G. M. Callender, did not give conclusive evidence of secondary deposits.

The death of Dr. Cranstoun Charles, at the early age of forty-five, will come as a surprise to America, which has already disposed of two editions of his "Physiological and Pathological Chemistry." He devoted most of his life to scientific research and was also a contributor of valuable papers to societies and an adept at giving to scientific subjects such a popular interest as made his writing very welcome to newspaper editors.

Another death I would mention is that of Mr. H. W. Denton Cardew, who passed away on the 25th inst., at the early age of thirty-three years. His fellow students and teachers held him in much regard, and he had succeeded in making himself an authority on electro-therapeutics. He also established the *Clinical Journal* which he carried on with no little courage on the lines he laid down for it before he commenced it. As he consulted me upon the scheme before he embarked on it, I am justified in mentioning the enthusiasm with which his plan was initiated and conducted.

The death of Billroth, on the 5th, seems almost as if it belongs to the events of Medical London, but that is only what you will feel in New York, and indeed wherever surgery is practised throughout the civilized world.

ON "THE DEFECT IN THE DENTIST."

To the Editor of the Medical Record.

Sir: Your article in the issue of January 27th, on "The Defect in the Dentist," seems to invite a reply, and I venture to offer some remarks. It is gratifying and timely that a medical journal should note the deficiencies in dental practice and point to the need of higher attainments than ingenious mechanism and clever devices. The use of aseptic methods and instruments is no doubt far less common than it should be in dental practice, but perhaps the number who are "behind the mark" in dentistry is not greater than it is in most other professions. The "mark" being on a level with the capacity for "taking infinite pains," perhaps those who are behind it can best be stimulated to reach it by more exacting discrimination on the part of those who seek services. I think, however, that most dentists that have any claim to the front rank are alive to the necessity of aseptic—or absolutely clean—methods and instruments, and are safely suspicious of lesions of the mucous membranes of the mouth that give any suggestion of syphilis. The latter subject has been ably presented before the New York Odontological Society, by Dr. L. Duncan Bulkley, and published in the *International Dental Journal*. In the discussion of the subject on that occasion, a distinguished syphilologist is reported to have expressed doubt as to the propriety of enlightening the dentist as to the nature of the patient's disease when sent for attention to the teeth; "in other words, whether it be right or proper to expose the dentist to a possible source of contagion, which he might not recognize, without some intimation," and he had "concluded, that considering the infinitesimal danger to the dentist, it is not proper to violate professional confidence

to that extent!" Such sentiments are hardly calculated to impress the dental mind with the great importance of perfect sterilization for the protection of the next patient, and the sense of perspective, in questions of ethics, seems to be strangely confused by such a statement.

Your criticism on the dentist's inability to provide "a genuinely antiseptic wash" that shall prevent decay of the teeth, is founded I think on false premises; namely, that decay cannot take place in a space that is made aseptic.

Dr. W. D. Miller, of Berlin, of whom all American dentists are proud, has added greatly to our knowledge of dental caries. His observations are that the tooth substance is first disintegrated by the action of acid, and then the softened dentine is invaded by bacteria. He says "the action of acids always precedes the invasion of bacteria," and yet he calls decay "of parasitic origin" and has devoted much attention to the relative antiseptic value of various agents for mouth washes as prophylactics. He has, however, admitted that there has been no evidence that they ever had any effect. In 1884 Mr. Miller announced that copper amalgam was the only filling material exerting a continual antiseptic action on the walls of the tooth, and that "the very substance of the tooth itself becomes antiseptic." This material had been receiving some attention, and various supposed virtues had been attributed to it, but following this announcement a copper amalgam epidemic prevailed for five years or more among the dentists of the United States and Canada. Other considerations were lost sight of, and its antiseptic properties were accepted as equivalent to a demonstration that it would prevent recurrence of decay. Gradually, however, after a time, it became apparent that new decay would begin and progress at the margin of such fillings, just as often, and quite as rapidly, as if the material were a perfectly inert substance. Its popularity has now vanished from among dental practitioners in America, and its use is seldom referred to, I think, except to condemn it.

The demonstration of the antiseptic properties of this material, by Dr. Miller, has induced Drs. Sonnenberg and Mayer to use it experimentally for filling cavities in bone, caused by morbid processes which they expect, presumably, to hold in check thorough the antiseptic action.

The failure, however, of such an active germicide to prevent dental caries from commencing in direct contact with it, suggests, at least, great doubt whether antiseptic agents applied in any way will ever be an effectual prophylactic so far as this process is concerned. We are obliged to fall back upon cleanliness as our only reliable preventive. No tooth can decay, if its surface can be, and is kept clean. Frail and defective structure makes more imperative the practice of all the means by which this may be effected. Dense and perfect teeth, such as may occasionally be seen, often resist disintegrating influences although never cleaned excepting by the attrition of food in mastication; but in proportion as teeth are obnoxious to decay, must they be cleansed by artificial means, or suffer the consequences.

Respectfully yours,

J. Morgan Howe, M.D.S., M.D.

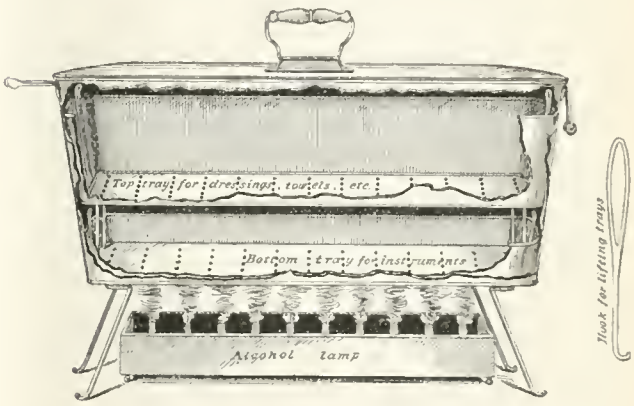
New York, February 17, 1894.

Abscess of the Liver gives history of hepatic tenderness, frequently more or less jaundice, and the increased area of dulness extending downward. The abscess, in many cases, follows in the wake of suppurative disease elsewhere—from the portal circulatory area, a suppurating catarrh of gall-bladder, osteomyelitis, or pyæmia.—Schafer.

Metallic Thread is indispensable for bony suture, where there is much traction. In buried sutures of soft parts it is of capital importance to draw upon them as moderately as will answer. This is most favorable to good and solid repair.—J. L. C.

New Instruments.

A PORTABLE STERILIZER FOR PRIVATE OPERATIONS.[1]



By WILLY MEYER, M.D.,

NEW YORK,

PROFESSOR OF SURGERY AT THE NEW YORK POST GRADUATE MEDICAL SCHOOL AND HOSPITAL, ATTENDING SURGEON TO THE GERMAN AND NEW YORK SKIN AND CANCER HOSPITALS.

Since von Bergmann, of Berlin, has shown, at the Tenth International Medical Congress (Berlin, 1890), that with the aseptic wound treatment we can accomplish the same results as with the antiseptic, and that, moreover, it is simpler and exposes the patient to less risk, the operating physician has to follow this progress, lest he should be left in the rear.

Certainly it is not easy for the surgeon to give up a method which he has long learned to master in every detail and upon the good final results of which he has looked as sure, almost guaranteed, to put in its place another one. And yet, anyone who, by employing the aseptic method, has been freed from anxiety in regard to corrosive-sublimate- or iodoform-poisoning; anyone who, after an operation conducted according to strict aseptic principles, has seen the wound rapidly and firmly heal without the slightest reaction, although it was entirely closed with stitches and not drained, will no doubt at once be equally enthusiastic in his praise of the aseptic method as he formerly was of the antiseptic one.

Of course we cannot claim that we now have entirely passed the antiseptic era and have entered the aseptic. Both methods of wound treatment will continue to co-exist and must in many respects be combined, though the aseptic will generally take the lead.

The two established fundamental principles of aseptic surgery—sterilization of the instruments by boiling in one to one and a half per cent. soda solution, and of the gauze for the dressings, of silk, drainage tubes, gauze-sponges, nail-brushes, and towels by steam—are well known. They cannot be improved, nothing new can be added to them. What has been left to us is: to make use of these two principles in as practical a manner as possible, especially by constructing apparatuses which can be bought and easily used by every practitioner in his private work.

In public and private hospitals matters have been arranged for us in a most commodious way. The operating nurse boils and steams the material in large vessels, put up in or near the operating room. We enter the latter and can, after proper self-disinfection, begin our work.

Different in private practice. As far as I know there is at the present time no handy "portable sterilizer" for sale, at least, not in this country, which is adapted for private operative work; provided you do not look upon

[1] Apparatus presented and paper read before the Section on Surgery of the New York Academy of Medicine, January 8, 1894.

the clumsy so called Arnold's milk sterilizer as one fit for general use.[1]

Of course, we always could boil our instruments at the patient's home, with a special facility if we use the well-known Rotter's sterilizer. But dressing, drainage-tubes,[2] gauze sponges, nail brushes, etc., had to be prepared at the doctor's home and carried along in special covers, best metallic ones. With reference to the towels, which surround the operating field, we had to satisfy ourselves with those which had been ordinarily washed and then before the operation immersed in an antiseptic lotion.

Eugen Braatz, the former scientific assistant of Professor Czerny, of Heidelberg, at present head of a private surgical clinic at Kœnigsberg, Germany, a gentleman who has done a great deal for developing and simplifying aseptic surgery, has devised a portable sterilizer.[3] It is, however, as it seems to me, according to his description, comparatively small and not well adapted for preparing all the material needed for a major operation at the patient's home. It is possible, also, that other colleagues have constructed something similar to, or even better than, that which I am going to present to night. If so, it is unknown to me If better, especially if more practical, it shall and will, no doubt, have the preference.

As you see, Mr. Chairman and Gentlemen, my apparatus has been constructed according to the well-known Koch's steam pot (see Fig.). A kettle of copper, nickel-plated, top, 17 by 8½ inches; bottom, 15½ by 7;[4] height, 6½ inches, with two lateral wooden handles[5] and a lid, which also has such a handle, carries in its bottom a perforated tray, as we know it from Rotter's apparatus. The latter has a brim an inch and a half high, and two upright perforated metal handles in which you can engage a blunt nickel-plated hook for the purpose of lifting the tray out of the boiling water.[6] A pair of such hooks accompany the apparatus. Two and one-half inches above the lower bottom tray, stands, on metal feet, a second perforated tray, with top tray, also with a hole in its handles. It has a brim of three and one-half inches height and near to its inner side a small gutter which runs all around and is punched by small holes three inches apart, for the outlet of the condensed steam, provided any should gather inside of the tray, which, however, does not occur according to my observation. Its brim does not touch the wall of the kettle. It receives all the other material, dressings, etc., mentioned above. On account of the distance between the brim and the kettle wall the top tray will not be moistened by the condensed steam. Further accessories are: a stand of nickel plated iron, and an alcohol lamp with ten Bunsen burners.[7]

After conferring with Messrs. Richard Kny & Co., of this city, who make the sterilizers, I have selected as material, nickel-plated copper for the outside kettle as well as for the trays. They can thus be easily and well cleansed. They are simply rubbed off and wiped dry with a piece of gauze or a towel and need no special scrubbing.[8] If so ordered, the apparatus can also be had of agate- or emaille iron, and of the so-called German silver, a combination of sixty per cent. copper, and twenty per cent. each of nickel and tin. However, the agate, also emaille, will in time come off the iron, which then cannot be cleansed so well, and the German silver made here is too thin.

To have my sterilizer as light as possible and yet durable, I have tried my best to find here and in factories of the neighboring cities a combination of other metals with aluminium which would enable the latter to permanently stand the boiling soda solution. My efforts have so far been futile. Aluminium alone, though now used for all sorts of cooking utensils, is slowly dissolved by the boiling soda solution. A proper combination with other metals to make it more resistant has not yet been found. Most probably it will be found in the near future. Then of course the aluminium should be "the" material.

The following points might with propriety be claimed as practical in my sterilizer:

1. It has sufficient inside space to hold everything that is needed for "the operation as such." Instruments (best wrapped up in a piece of gauze or a towel), dressings, etc., all can be easily put into the sterilizer at home and the latter then carried along with the help of this cover of gray canvas with a leather handle, as a doctor's satchel.

It would be absurd to call a "portable" sterilizer only then practical, if it is large enough to receive "everything" that we should like to sterilize for an operation. It is and must be sufficient if the apparatus permits of sterilizing at the patient's home, right before the operation, all that material which will come in direct contact with the wound and its immediate surroundings. The linen aprons or coats for the operator and his assistants will naturally never find room besides all the other things in a "portable" sterilizer. They must be steamed at home, probably best in the cheap Arnold's milk sterilizer, then wrapped in a clean or sterilized towel and carried along. Two, not too heavy, linen aprons will, however, find room in my large-size sterilizer, besides the other material. It certainly means a great saving of time and annoyance, if the doctor need not sterilize all the material at his home and then carry it along either with the whole apparatus or separately wrapped in sterilized towels or pieces of gauze. Besides, the material boiled and steamed just before the operation is more reliable, because it was not handled before.

2. All material necessary for the operation as such, can be sterilized at the patient's home just before the operation. The only exception we need make is for catgut, which will best be rendered aseptic for private use by the well known method: roll on glass spools; then immerse for *a*, twenty-four hours in ether; *b*, twelve hours in alcohol; *c*, twenty-four hours in a "watery" solution of corrosive sublimate 1 to 1,000; *d*, preserve in alcohol.

3. Instruments and dressings, with all the other necessary materials for the operation as such, are rendered aseptic in the same apparatus at the same time.

4. The inner space is so arranged that two quarts of water fully cover all the instruments which will be needed for a major operation. There is a mark on the inner aspect of one of the handles of the lower tray as well as on one of the narrow sides of the kettle which corresponds to the level of the water when two quarts have been filled in. Thus measuring is avoided. If we add two heaping table spoonfuls of pulverized soda, the 1 to 1½ soda solution ordinarily used for boiling instruments is ready.

5. The alcohol lamp, if filled up to a mark near the upper border of the two outside burners, viz., No. 1 and 10, holds exactly as much alcohol as is needed to bring to thorough boiling (bubbling), these two quarts of soda water of a middle temperature of about 55 to 60° F., viz., the average temperature of the Croton water here in winter (this takes six minutes), and keep it boiling for fully twenty-four minutes. Thus the act of sterilization lasts exactly thirty minutes. As experiments have shown me, two quarts of water of about 60° F. heated with this lamp need six minutes, of 50° seven minutes, and of 40° nine to ten minutes to proper boiling. With water of a temperature of 50° the material is then steamed for twenty-three minutes, of 40° F. for twenty to twenty-one minutes.

[1] In the Arnold's sterilizer one can steam all the material for the dressing, etc., but cannot boil instruments. Another apparatus is thus needed for the latter purpose.

[2] Drainage-tubes contain sulphur. They are, therefore, once boiled in soda solution and then preserved in a three per cent. carbolic or 1 to 1,000 sublimate solution until use, when they are steamed with the other material.

[3] Die Grundlagen der Asepsik, etc. Stuttgart (Ferd. Enke), 1893, p. 65.

[4] This is amply long to also receive an obstetrical forceps. The latter should have metal handles. The wooden or hard-rubber handles do not stand frequent boiling.

[5] During sterilization both handles must be turned up, lest they should be burned by the immense flame.

[6] This tray may, of course, be subdivided, as in Rotter's apparatus, if so desired and ordered.

[7] The sterilizer is sold in three different sizes. The one described above and represented in the figure is No 1, the largest It is the one the surgeon should buy; it will answer all purposes. Price, $21. No. 2 measures: bottom, 15½ × 6½; top, 17 × 8; height, 5½ inches; price, $20.50. No. 3 for minor operations; its measures are: bottom, 15½ × 5½; top, 17 × 7; height, 4½ inches; price, $20. All three have the same lamps and need half an hour for sterilization. They are all made of copper, nickel-plated. Without nickel-plating they cost $2 less.

[8] Tin will not hold nickel-plating for any length of time. If not nickel-plated, it rusts. Copper needs polishing.

This time is fully sufficient to "reliably sterilize" all the gauze, towels, etc., no matter how tightly they have been rolled or packed (Braatz), in this apparatus. Schimmelbusch says, in his "Anleitung zur aseptischen Wundbehandlung, Berlin, 1892, page 84: Steaming of the dressings ought to continue for one-half hour;" and on page 92: "In order to have the dressings thoroughly sterile, half an hour's steaming might suffice, counting from the moment the apparatus is fully filled with steam." On page 86 he states with reference to a small-sized sterilizer of his own device, which also works with boiling soda solution: "Experiments with reference to killing anthrax-spores, and disinfecting dressing material, which had been saturated with pus, showed certain death to all micro-organisms within fifteen minutes in every instance." Schimmelbusch does not give any reason why he nevertheless puts down thirty minutes as the proper time for sterilizing gauze. E. Braatz remarks, in explaining the proper handling of his portable sterilizer (l. c.): "All objects to be sterilized by steam are left in the same for about twenty minutes, counting from the moment the water boils thoroughly." And on page 139 he says: "The objects remain in the apparatus for half an hour, in the small pot (page 135) at least one-quarter of an hour after steam is in full generation. Then everything is absolutely sterile and more reliable than it might be accomplished with a strong antiseptic in days, with five per cent. carbolic in weeks." Basing on these facts I have set down the time for sterilizing gauze, etc., as stated.

A thermometer put low down in the tray in the middle of a gauze compress, which was besides tightly wrapped in a towel, showed 212° F. four and a half minutes after the water had commenced boiling.

It is self-understood that a gas-, or gasoline burner may as well be used, and that anybody, if he be in a hurry, may at once pour into the kettle hot instead of cold water. He then, however, must note the time when boiling commences and stop sterilization about twenty to twenty-five minutes later. I had to arrange my sterilizer for cold water, of course, in the assumption that hot water was not always on hand at our arrival at the patient's home. It must be stated that the lamp produces a very intense heat. If possible, the sterilizer should be placed, therefore, at the patient's home, on a table with marble top or on the range.[1]

On account of the time needed for proper sterilization —one-half hour—it is advisable to at once put up the apparatus after our arrival at the patient's home. To do so we will then best proceed in the following way: Lift out upper tray; take instruments out of their cover (gauze, if boiled, produces an annoying foam on the surface of the water); replace them in bottom tray; pour in two quarts of cold water, that is, up to the mark on the handle, and add two heaping tablespoonfuls of pulverized soda;[2] put the top tray into the kettle and place in it all the other materials;[3] close the kettle with the lid and put it on stand; fill the lamp with alcohol up to the mark near the upper border of the two outer burners;[4] light it.

Now the apparatus is self-acting. If the lamp extinguishes, that means, if after thirty minutes the last drop of alcohol has been consumed, we can rest assured that everything in the apparatus is sterilized and ready for the operation. It will be found that the gauze thus steamed is not wet, but almost entirely dry. To be quite sure, one of the towels should be spread on top of the dressings.[5] Meanwhile the patient will have been narcotized, shaved, and prepared on the table.

[1] When once lighted, the alcohol should burn until used up. It is almost impossible to extinguish the lamp at any given moment. The lid, as it is at present, with short borders, shuts off the air from the surface of the alcohol. But oxygen can be still drawn through the Bunsen burners. In order to be able to extinguish the lamp at will, the lid must go down to the surface of the object on which the lamp stands, or the burners must go up to the lid. The latter will probably be arranged accordingly.

[2] The knives should not be put in; a few minutes' boiling makes their sharpened edges perfectly dull. They will be best rubbed with a piece of sterilized gauze which has been soaked in alcohol or ether. A few seconds' boiling in the soda solution the edge stands well. This time suffices to kill the ordinary infectious cocci.

[3] Gauze, cotton, etc., may be rolled very tightly in small packages, as stated above; it has been proved that the steam reaches and disinfects every spot. However, the top tray of sterilizer No. 1 has sufficient space for loose gauze, cotton, etc. The gauze and cotton should be cut and rolled, or folded into compresses of proper size and then rolled "before," not after, sterilization.

[4] We should always order to send for one pint of alcohol, which costs 35 cents. The lamp, up to the mark mentioned, holds exactly 400 c.c. equal to 13½ ounces. The rest can be utilized for disinfecting the hands after scrubbing with hot water and green soap, and before using the sublimate solution 1 to 1,000 or 1 to 2,000 (Fuerbringer's Method).

[5] Too much stress has been wrongly laid upon the necessity of a dry condition of the steamed (aseptic) gauze. Aseptic (steamed) gauze, which, say, is moistened by the condensed steam, is absolutely harmless and perfectly reliable, just as much as that which had been artificially dried or kept dry in the apparatus. The direct application of moist "steamed gauze" on a fresh aseptic wound may perhaps be uncomfortable, but will certainly never involve a risk.

The boiled soda-water in the kettle can be well used for immersing the instruments in other vessels, during the course of the operation as is required in an operation which is conducted on strict aseptic principles. If anybody prefers to adhere to his former mode of proceeding, he may keep the instruments immersed in a two or three per cent. carbolic solution. He ought to be aware, however, that the water must be boiled which he uses for making up the solution. He will better add two tablespoonfuls (six teaspoonfuls) of pure carbolic acid to the two quarts of soda solution (vide Schimmelbusch: Aseptische Wundbehandlung, Berlin, 1892, page 69), thus making a one to one and one-half per cent. solution of carbolate of soda, and put the instruments in this fluid. This seems to me to be the best mode of proceeding, as the plain soda solution makes the instruments quite slippery. Or at last he may keep them spread on a sterilized gauze compress and have the blood, etc., now and then washed off in a vessel filled with the sterilized soda solution.

The only plausible objection which could be found to my sterilizer is that the instruments boil four times longer than necessary, namely, twenty four minutes. They only need five minutes for proper sterilization. The surgical instruments of to-day, made entirely out of metal, in one piece, will, of course, stand this. Nickel-plating is superfluous, since we use soda solution for boiling (Schimmelbusch, loc. cit., page 72). It therefore need not be renewed, if in course of time it be damaged by the boiling.

If anybody is very particular in this respect he may proceed as follows: If he be busy with the patient, he can make use of the self acting feature of the sterilizer, viz., first fully steam the material in the top tray, everything being arranged as stated above, only leaving out the bottom tray with the instruments. (For this purpose one of the narrow sides of the kettle also has a mark inside, to show when two quarts of water have been poured in.) When the water ceases to boil he will lift out the top tray with the help of the two hooks, put in the lower one with the instruments; replace the top tray and lid; pour two ounces of alcohol (= five tablespoonfuls) into the lamp (which keeps the hot soda solution boiling for exactly five minutes longer), light it. The material in the top tray will then be steamed five minutes longer, that means, in all, almost half an hour. If the doctor be at leisure, or the assisting doctor or nurse has charge of the preparations, five to six minutes' time and a little trouble can be saved by noting the time the lamp has been lighted. Twenty five minutes later the lid should be removed, top tray lifted out, bottom tray with instruments put in, top tray and lid replaced. When the lamp gives out, everything will be ready for use; the instruments boiled five minutes only.[6] If the apparatus shall be used for sterilizing instruments only (forceps, etc., in confinement cases), five ounces (= twelve tablespoonfuls) of alcohol will be found sufficient to bring to thorough boiling the two quarts of soda solution and keep it so for five minutes.

Mr. Chairman and Gentlemen: I should be pleased if this small apparatus should be found practical also in the hands of other colleagues and thus contribute to still more rapidly generalize and introduce the aseptic method in our private operative work.

[6] On account of the continuous slight loss of steam at the sides of the lid and therewith continuous slow decrease of the amount of water, it may be wiser for a doctor, who does not want to have his instruments boiled all the time, to use five intermediate minutes for sterilizing the instruments. It might, with other words, be preferable to remove the lid, say, at the twelfth, fifteenth, eighteenth, twentieth minute of the act of sterilization, lift out top tray, which alone had been put in at first, put in bottom tray with instruments, replace top tray and lid. Five minutes later the bottom tray is lifted out. Top tray and lid having been replaced, the apparatus is left to its self-acting work.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending February 24, 1894.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	6	3
Scarlet fever	116	20
Cerebro-spinal meningitis	1	6
Measles	470	35
Diphtheria	202	58
Small-pox	29	5
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

Essentials in a Healthful Home.—The site for a house should receive careful attention of the tenant, purchaser, or of one proposing to build. A good site may mean life and happiness, and a bad one disease, suffering, and death. 1. It should be dry; avoid, as you would death, a damp location. In a town or city carefully ascertain whether or not it is on "made ground." Avoid it. Avoid ground underlaid with clay, for it will always be damp. 2. Elevated on a hillside or gentle knoll, never in a hollow. The hillside is warmer and drier than the hollow. 3. Not close to a swamp, slow river, milldam, or land which is overflowed a portion of the year, nor in such a place that the prevailing winds will bring to the house pestilence from a milldam, etc. 4. In as good a neighborhood as possible, away from factories, saloons, etc., and near schools and churches. 5. In a village or town build on as large a lot as possible, thus securing air and sunlight. Build back from the street, thus avoiding the dust of the dry season and the curious gaze of every passer. Secure a yard in which trees and plants will furnish both exercise and health 6. In the country build back from the highway, giving an abundance of room for trees and shrubbery about the house. Do not select a place where your family will be isolated from all social intercourse, so necessary to health of mind and body.

For the aspect, let the house be so placed that it will receive the most sunlight and fresh air, especially from the summer winds. Avoid, even if offered rent free, a damp, dark house, with no chance for the free air of heaven to sweep through it. If the house is only one room deep, it does well to face it to the south or southwest; but if it is two rooms deep, those on the north side never receive any sunlight, and are apt to be damp. For a double house it is best to face to the east. Then the morning sun will warm up the front and the afternoon sun the rear of the house, and thus all the rooms will be bathed in light and warmth. The living-rooms should always be warmed by the morning sun. This hint is worth a great deal as a health matter. For when the sun cannot enter, the doctor must enter. If the cold winds from the north and west are severe in the winter, they may be broken by a cluster of evergreen trees planted on those sides. In country places a good aspect should be secured without reference to facing the house square with the street. The writer has recently erected a house of fourteen rooms, all of which face either the south or west, except two hall rooms and the bath-room. . . . The living rooms are all on the south, while hall and kitchen effectually protect them from cold winds.—*Pacific Health Journal.*

Specific Treatment of Enteric Fever.—E. Fraenkel (*Deut. med. Woch.*, October 12, 1893) says that at present there is no longer any doubt that enteric fever is produced by Ebert's bacillus. He then refers to experiments which have shown that animals could be made immune against this infection by the injection of thymus cultures heated up to 60° R. The author was then led to try a similar treatment in man. Thymus cultures were heated up to 63°, and their complete sterility proved by experiment. The injection was made at first into the subcutaneous tissue of the iliac region with every precaution. Subsequently it was found more convenient to inject into the glutei muscles, and in this way it never became necessary to interrupt the treatment. Of fifty-seven cases of enteric fever thus treated, twelve were severe, the rest being of moderate severity. On the first day 0 5 c c. were injected, and no change was noticed in the condition of the patient. On the next day 1 c.c. was given. This was followed by a distinct rise of temperature, with slight shivering. On the third day the temperature fell, and twenty-four hours later there was a further drop. If the treatment was stopped the temperature again rose, so that 2 c.c. were administered with similar results as before. The course of the temperature determined the further treatment. If there was no rise injections were given at two days' interval, the dose being increased each time by 1 c.c. The fever lost its continued character and became intermittent, and in a short time there was complete apyrexia. Along with the fall of temperature there was profuse sweating and copious diuresis. The diarrhœa mostly ceased. The patients appeared to be convalescent while rose spots and enlargement of the spleen were still present. Feeding could be proceeded with more quickly, and fourteen to sixteen days after defervescence the patient was able to get up. Complications and relapses could not be avoided, but the treatment was efficient in the relapse. This treatment secures a rapidity and uniformity in the course of the disease not hitherto observed. Rumpf (*Ibid.*) says that the question arises whether similar results may be obtained by the use of sterile cultures of a micro-organism having nothing to do with the disease. Cultures of the streptococcus were used at first, but ultimately the β. pyocyaneus, as having slight or no pathogenic properties. Thymus cultures were heated up to 62°, and 0.5 c.c. were injected as above, when a slight rise of temperature occurred. The rise was also noted on the second day, but on the third it was inconsiderable. More often, and especially in severe cases. 1 c.c. was given on the second day, and then forty-eight hours were allowed to elapse. The temperature soon fell, and the pulse and condition of the patient improved greatly. If the injections were discontinued he fell back again. If the temperature did not fall, 2 c.c. were given on the fourth, 4 on the sixth, and 6 on the eighth day. No ill-effects were noted, or, at most a little shivering. In six to eight days the fever and other symptoms had disappeared, and convalescence was rapid. Sometimes a relapse occurred, when the same treatment was also effective. In thirty cases there were two deaths, one from hemorrhage and one from pneumonia. The importance of being able to influence an infective process by introducing the products of some dissimilar micro-organism is obvious.

Chlorides in Cancerous Diseases.—Dr. Schöpp has been investigating the excretion of chlorides by carcinomatous patients. The urine was examined in each case on several successive days. The conclusions come to are as follows: The relation between intake and excretion of chlorides is not constant for all cases of cancer. The remarkably large decrease of excretion in some cases of cancer is chiefly dependent upon the extent of ulceration, and is caused by the large amount of chlorides contained in the discharges. The decrease is also affected by the rate of growth of the cancer, and is inversely proportional to the loss of flesh. There are no grounds for assuming a resemblance between the decrease of chlorides in cancer and that which occurs in febrile attacks.

Some Educational Appropriations.—The Pennsylvania Legislature is very stingy in its grants to the State Board of Health, but makes it up in appropriations to medical schools in Philadelphia, among three of which it has distributed this year the respectable sum of $330,000.

ELIMINATIVE AND ANTISEPTIC TREATMENT OF TYPHOID FEVER.

By W. B. THISTLE, M.D., L.R.C.P. LOND.

DEMONSTRATOR OF ANATOMY, TORONTO UNIVERSITY; PHYSICIAN TO VICTORIA HOSPITAL FOR SICK CHILDREN; LECTURER ON DISEASES OF CHILDREN IN WOMAN'S MEDICAL SCHOOL.

IN an article on this subject which appeared in the *Canadian Practitioner* for April, 1893, I introduced to the profession a form of treatment which seemed to follow closely upon our knowledge of the nature and *modus operandi* of the infective agent, and which in my hands had given exceptionally good results. In connection with that paper I published histories of thirteen consecutive cases, with the average attainment of normal temperature and establishment of convalescence on the eleventh day. Another noticeable feature in that series was the complete absence of accidents of any kind and of the usual unfavorable and distressing symptoms. Since then my experience and that of my friends who have given the treatment a trial has been such as to increase my confidence in its efficacy, and to establish even more securely the correctness of the views I then put forward.

I now beg the liberty of returning to the subject, and of presenting an additional number of cases. Before doing so, however, I may be permitted, as in my former paper, to outline briefly the nature and pathology of the disease, and so to clear the way for discussion.

It is now well established that typhoid fever is the condition which follows infection of the organism by a specific form of bacillus. What concerns us more particularly is the manner in which the bacillus brings about the changes which we attribute to it, for it is only from a knowledge of that kind that we can work out a successful treatment. The bacillus entering the body would, under ordinary circumstances, be carried quickly through the stomach and upper bowel until its onward course becomes somewhat retarded by the ileo-cæcal valve. In this situation the intestinal contents are perhaps most alkaline. This region is, therefore, most favorable to bacterial growth. Multiplication occurs with extreme rapidity, so that the intestinal contents in a few days teem with countless numbers of fungi. They are, however, by no means confined to the intestine, but are conveyed by the absorbents into the follicles in the intestinal wall, and through the radicals of the portal veins to the liver, and so on through the system generally. They may be found in the solid viscera, tissues, and fluids throughout the entire body. That the main culture is, however, in the intestine is borne out by the fact that immense numbers are in the evacuations, and that infection is universally attributed to unsterilized fecal matter. Keeping pace exactly with this process in the bacillus, is the production and accumulation of a chemical substance—a biproduct, which is a necessary element in the vital activity of the bacillus. By separating this substance from cultures, and experimenting with it, many of its properties have been determined by Brieger, Novy, Sims-Woodhead, and others. It was found to produce local as well as what may be called constitutional effects. Sims-Woodhead likens it, acting locally, to a "caustic." Its first and mildest effect is to stimulate the cells of the part, causing them to become swollen, and to increase in their rate of multiplication. If, however, the toxine is allowed to remain long in contact with the cells, or if it is in sufficiently concentrated form, instead of irritation and increased activity the cells lose their vitality and necrosis takes place. As examples of its constitutional effect we may instance fever, delirium, tremor, lethargy, or its mydriatic action on the pupil. If a large dose be given to an animal, it speedily dies narcotized; if a somewhat smaller dose be given, and repeated for a time, the animal gradually merges into coma, and shortly dies. The toxine, is, in fact, the weapon of the bacillus, without which it would be a harmless particle of vegetable protoplasm.

The symptoms generally are determined by the amount of poison in the body, and, in the case of different individuals, by a varying degree of susceptibility, or a varying degree of virulence in the poison itself. The local disturbance is determined by the quantity of the poison in contact with the tissues, to its degree of concentration, and to the length of time it remains in contact. It is by noting these facts regarding the toxine that one gets the key to the situation. Look, for example, at the case of the intestinal follicles; why is it that the tissues here suffer to such an extreme degree? Surely not from any selective action of the bacteria, but rather from the fact that the follicles are in close proximity to the main culture, and are surrounded by lymph sinuses into which empty the lacteal ducts of the surrounding villi. Each follicle is, in fact, the reservoir to which is conveyed both poison and bacteria absorbed from the intestine. The bacteria and poison carried to other parts of the body produce in a minor degree the same results. Molecular death is much increased wherever this poison is present, but as a rule ulceration takes place only in the intestinal nodes. The reason seems clear; the bacilli invading the follicle are at first precisely in the same position as a similar colony in like tissue in any other part of the body, and after having given rise to a certain degree of disturbance, would, as in the other situations, be overcome by the tissues, seldom giving rise to necrosis *en masse*. But the anatomical conditions being different, the lymph tissue in the intestinal follicles wages unequal war, since reinforcement both in the way of fresh bacilli and of poison absorbed from the intestine is constantly arriving, carried by the lacteals of the surrounding villi, until, eventually, the poison becomes so concentrated that all resistance is overcome, and the follicle undergoes necrosis. The slow percolation of fluid through the follicles aids in their destruction, as it favors concentration and prolongs the period of contact.

As a corollary to this it appears that ulceration of Peyer's patches is by no means an essential or necessary result of typhoid infection. For, if the base of supplies should be cut off, the bacteria already in the follicles might reasonably be expected to produce the same results, and disappear in the same manner as a like number of bacilli located in similar tissue in any other part of the body.

The treatment which I advocated in my first paper, and to which in the series of cases I have to report I adhered throughout, is based on this conception of the pathology of the disease. It consists, first, in eliminating as speedily as possible, both the main culture and toxine in the intestine, and also the poison held in solution in the body fluids throughout; second, in diluting

as much as possible the toxine which is in contact with the tissues, and in that way controlling to some extent its destructive or irritant defects, and third, in the use of substances which will destroy the bacilli still remaining in the intestine, or retard their rate of multiplication.

Elimination is accomplished by securing free and thorough evacuation of the bowels daily by the use of purgatives. This daily purgation, as much as seems necessary, keeping in view the evidence of toxæmia, is continued until the temperature becomes normal There can scarcely be doubt about the possibility of clearing the intestine of the bacteria and poison which it contains. Argument to prove that point seems scarcely necessary. Since the evacuations constantly contain bacteria, and of necessity their generated poison, it follows that purgation must result in elimination of both, and. if the process is constantly repeated. there is a continued disappearance of bacteria and poison. which would otherwise be absorbed and carried throughout the body. In fact, by the agency of purgatives there is a frequent withdrawal of an additional dose of poison, which in the absence of any such procedure must surely have gone to increase the amount already in the tissues. But purgatives do much more than simply empty the intestine. They at the same time cause a copious flow into the bowel; by their use the body-fluids are drained into the intestine. The amount which can be drained off in this way is very great, and in order that we may have some idea of it, let us calculate on the basis of Lauder Brunton's experiment, by which he demonstrated that in four hours, by injecting a solution of magnesia sulphate, he was able to produce a secretion almost equal to one drachm to every square inch of intestine acted upon. But we scarcely need to enter into a calculation, as the amount of fluid which follows the exhibition of a cathartic is sufficient evidence. The important point is that the body fluids from which this secretion is derived hold in solution both the poison which has been absorbed from the culture in the intestine and that produced by the bacilli located in the various tissues of the body.

There are many somewhat indirectly beneficial results to be obtained by free elimination. The weakness of typhoid patients, which is of the same nature as the weakness of a drunken man, disappears or grows less, keeping pace to a great degree with the lessened toxæmia. In a similar way, anorexia, nausea, or inability to digest and assimilate food, in every case, in my experience, grows less and less if elimination is free and continually secured. My patients have in every instance been able to take large quantities of nourishment, and without difficulty. Owing to the improved capacity in this respect, while on the one hand large quantities of fluid are constantly drained off, on the other hand this fluid is replaced by a large quantity frequently ingested and assimilated. So exhaustion from the frequent and copious evacuations is prevented. We may say that an exchange has simply been made. The body-fluid with its contained poison is replaced by a like quantity without that element.

In addition to the large quantity of food taken, I invariably direct that the patient be given water in large quantities at frequent intervals, with the twofold object of aiding the elimination of poison by its diuretic and flushing action on the kidneys, and of keeping up the volume of body-fluid. Thus concentration of poison is prevented, which must inevitably result if the ingestion of fluid does not keep pace with its withdrawal. By preventing this we are following the plain teaching of pathology, since the destructive effect of the poison is increased in proportion to its concentration (Woodhead). This practice of dilution is inseparably connected with the practice of free and continuous elimination by purgation.

As to the other factor in the treatment, *i.e.*, the use of antiseptics, I hold it in light esteem when compared with elimination and dilution. Yet in all my cases I have used intestinal antiseptics, and I believe with a great deal of benefit. It seems to me that if one can completely deodorize the intestinal contents by the use of salol, that it must do this through its destructive action on the ordinary intestinal bacteria, and very likely will act in the same way on the germs of typhoid, if occupying the intestine. In this connection I should like to point out that much larger quantities of antiseptics can be used, if associated with free purgation, without their toxic effects arising, than if given alone.

In a departure from tradition and teaching such as this treatment, while one may be disposed to give full credit to its logical correctness, yet there are questions which must be answered in a satisfactory manner before it can be applied with confidence. In my first paper I dealt with several of these, more particularly and at length with the supposed greatly increased liability to perforation and hemorrhage involved in the use of purgatives. Keeping in mind the pathology of the disease, let us first notice the question of perforation. This, of course, presupposes deep ulceration, a condition the occurrence of which in cases seen early, and where free elimination has been secured throughout, is directly opposed to the inferences of pathology. I have already in this paper expressed the opinion that intestinal ulceration is by no means an essential in typhoid fever, and depends upon the retention of the poison. So that in cases seen early, and where elimination has been properly secured, we are not even confronted with this difficulty, and may proceed to purge as freely at a late as at an early stage of the disease in so far as the danger of perforation is concerned. Many cases, however, come under observation late in the course of the disease, and in these cases, where the poison has had full play, and where there are other signs of intoxication, we must suppose the presence of ulceration.

In dealing with this question I may be permitted to quote from my former paper: "Suppose the ulceration to be deep at the time the patient comes under observation, are we then to allow the caustic to continue in its work of cell destruction, or are we to attenuate and remove it in the way indicated? Certainly the latter plan seems the reasonable one to adopt. It is, however, objected that ulceration is, perhaps, so deep that any increase of movement, consequent on purgation, may cause rupture. Let us here notice what follows on the administration of a purgative medicine. There is increase of peristaltic movement; but here we must remember that we have made no radical change, but have simply increased the rate of existing movement. Moreover, by purgation, we get rid of irritating matter and gases which were, perhaps, exciting violent peristalsis. And again it may be urged that to accomplish this removal we must increase the expulsive movement still further; not necessarily so, as at that portion of the intestine, for purgatives act chiefly by virtue of their power to produce free secretion. Consequently the process partakes largely of the nature of a flushing out. Not only does purgation not increase, but it can be proven that it actually diminishes the danger of perforation. It is obvious that the more the intestine is distended, the thinner those structures which form the floor of the ulcer become. Now this condition of distention is common in typhoid, and depends on paralysis of the intestinal muscles resulting from the action of the toxine on the nerve-centres Hence, if by purgation the cause of the paralysis be got rid of, there is a return of muscular tone, which is the condition least favorable to the occurrence of perforation. Let us now turn to the question of hemorrhage. Hemorrhage can, of course, only occur from a vessel laid bare by the process of ulceration. At the outset, I should like to draw attention to two facts touching arterial hemorrhage. Gowers, speaking of the pathology of cerebral hemorrhage, says: 'The force that ruptures an artery is the pressure of the blood within it.' And, again, 'healthy veins may give way under extreme pressure, but arteries do so seldom, perhaps never.' Accepting these statements, then, and applying them to typhoid fever, we have the two factors in the production of hemorrhage

—the toxine corrodes the arterial wall, the blood-pressure ruptures it. If we remove the toxine from contact with the vessel, and diminish the intensity of its action, we certainly, as in the case of the intestinal follicle, limit the extent of damage to the vessel-wall. But it is claimed that increase of movement in the intestinal wall may cause laceration of the exposed artery. In other words, we are asked to believe that a vessel whose wall is so fragile that it may be broken by the slight increase of vibratory movement in the membrane in which it is lodged, is at the same time, if freed from this extra movement, capable of sustaining the blood pressure. Then, again, is it really a fact that increase of movement in the intestine involves strain upon the vessel which ramifies in its wall? One can understand readily enough how the vessel might be stretched, and possibly torn, as a result of paralysis of the muscular wall of the intestine, and its subsequent distention by gas. Purgation, then, to my mind, in no case causes rupture of an artery, but at all times tends to prevent its occurrence." In case, however, one should decide against purgation, on account of its supposed danger, he must accept the responsibility which the alternative involves of maintaining *in statu quo* the very condition which makes him apprehensive of danger.

In connection with the application of the principle of elimination there are several minor questions. First, in the event of the presence of diarrhœa, are purgatives indicated? The occurrence of diarrhœa must be a response to some irritant, and, if it continues, and is associated with evidence of toxæmia, we cannot infer that there is complete elimination of the exciting cause. In short, we simply follow the practice so general in, for example, either the symptomatic, or mycotic diarrhœas of children, and control the diarrhœa by giving a purgative. Because there are several watery stools in a day, it by no means follows that sufficient elimination is being secured, for the flow may be simply from the lower bowel, leaving the contents of the ileum untouched. Supporting this view is the fact that the diarrhœa is so often associated with indications of pronounced toxæmia, whereas the same number of movements in response to a purgative is followed by a marked loosening of toxæmia. With reference to this very point, a recent case is of interest. There was persistent diarrhœa during the second week, associated with tympanites, elevated temperature, and intense headache. Attempts had been made to control the flux by opiates, etc., but without success. The movements were as many as fifteen and sixteen per day. I advised three grains of calomel and asked the physician in attendance to note well the character of the motions which followed. He did so and reported the passage of an unusually large and extremely offensive stool, together with a large quantity of a jelly-like substance. Subsequently there was cessation of the diarrhœa and marked improvement in every respect. The purgative was repeated, and the patient became shortly convalescent. Second, is there danger of exhaustion from frequent and prolonged purgation? I have already pointed out that if patients are relieved from the poison, the appetite and power of assimilating food remain good. It is quite common to have patients take sixty ounces of nutritious food daily in addition to large quantities of water. I have, in practice, experienced no trouble whatever from exhaustion following upon purgation.

I have now to report twenty-nine new cases, making in all forty two consecutive cases. In the second series the treatment was practically the same as in the cases reported last year, with the exception that I gave myself more liberty in the choice of purgatives. I have used calomel, magnesia, sulph., pil. cath. co. U. S. P., Rochelle salts, pulv. sedlitz, and cascara sagrada. Purgation begun vigorously and continued until the temperature became normal, was the rule of treatment. It was also considered important to secure elimination as quickly as possible. I do not wait until next day; but a few hours after having given calomel or pil. cath. co., followed by pulv. sedlitz, excite the reflex by a glycerine enema. I have not noticed any difference in the effects produced by the different purgatives. All are alike useless, if they fail to purge. As to the antiseptic effect of calomel, there is not the slightest evidence. I have in several cases seen it given continuously in large doses without purging and without producing the slightest effect on the symptoms. It is in many cases impossible to keep up purgation by the use of calomel alone. But, if the dose of calomel be followed in two or three hours by a sedlitz powder, there is usually no difficulty. Occasionally the gums become sore, and it becomes advisable to substitute pil. cath. co. or magnesia sulph. for calomel, or, if but slight results are desired, a drachm of elixir sagrada may be given. The difficulty has never been in the way of preventing too vigorous action, but rather in securing sufficiently free movement. In looking over my charts, I find that five or six movements per day in response to purgatives has been about the rule until the symptoms somewhat abated, when purgatives were reduced to produce three or four movements. But if there were any aggravation of the symptoms, freer elimination was induced as quickly as possible, for I considered time an important element in this treatment. Salol has been given in nearly all cases in five- or ten-grain doses every three or four hours. With every capsule or powder, the patient was instructed to take a large draught of water.

Of these forty-two cases several were furnished by medical friends who were good enough to give the plan a trial. A number of these were, however, treated under my direction. The list includes hospital and private patients, perhaps a majority of the latter.

Analysis of Cases.—Cases came under observation on an average on the fifth day. I have no fatalities to record. Average attainment of normal temperature and entrance on convalescence on the twelfth day. Relapse or recrudescence occurred in three cases. No hemorrhage. No perforation.

Delirium occurred in only one case—a little girl—while under treatment, and when present when patient came under treatment, very shortly disappeared.

Tympanites in no case occurred during the course of treatment; and where present, when the patient was first seen, very quickly disappeared.

In fifteen cases rash was noted. In seven cases spots were present on the abdomen when the temperature was normal, and convalescence had begun. Bathing was had recourse to only for the purpose of cleanliness. Routine sponging once or twice a day; but in my own cases never required for the reduction of temperature.

Remarks.—Forty consecutive cases of typhoid fever, without death or accident of any kind, is an extremely good result. And, when we consider the duration of the fever and the comfort of the patient, instead of the usual distressing symptoms, this record is without a parallel, I believe, from any system of treatment. The fact that, in seven of this series of cases, the rash, perfectly typical, was coincident with normal temperature and convalescence, surely proves that typhoid fever can be aborted.

Medical Fees in France.—M. Dumontpallier sued a notary of l'Aisne, whose wife he had treated in 1892, before the civil tribunal of the Seine, to recover an honorarium of 1,500 francs. The lawyer, who had already tendered 700 francs, pleaded that this sum was sufficient. Hence the action. Having heard the advocates on both sides, the tribunal delivered judgment, basing its decision on the following grounds: "Seeing that in a question of medical fees the points to be regarded are the pecuniary situation of the patient, and the repute which the doctor may have acquired through his labors and his discoveries; and considering in the present case the position of the patient's husband and the medical eminence of Dr. Dumontpallier, the sum demanded is not excessive." The tribunal accordingly condemned the attorney to pay the fee of 1,500 francs in full.

UNSUSPECTED POISONING BY STERILIZED MEAT AND MILK OF TUBERCULOUS ANIMALS.[1]

By JAMES LAW, F.R.C.V.S.,

CORNELL UNIVERSITY, ITHACA, N. Y.

With an unaccountable shortness of vision, medical and veterinary sanitarians alike have never, up to the present hour, looked beyond infection by the tubercle bacillus in estimating the danger to man of tuberculosis in our flocks and herds. We find, accordingly, that the question kept continually before the public is that of the presence or absence of the tubercle bacillus from any food-product—meat, milk, butter, or cheese—furnished by the diseased or suspected animal. The question of the presence or absence of ptomaïnes or other toxic elements which are calculated to prove hurtful or even fatal to certain members of the human race, is not for a moment considered. Hence we are met by the argument that tubercle is rare in the muscular system of cattle, and that muscle juice is inimical to the bacillus, and that therefore the muscular tissue which makes up the great mass of the dressed carcass, may as a rule be safely eaten, even though the internal organs have been affected by tubercle.

In Germany and other European countries the flesh of animals in which the tubercles are found in only one organ, or in two related ones, is passed as wholesome. It is only when the tubercles are found in the bones, or muscles, or in the lymphatic glands situated among these, or finally, when the tubercles are so generally distributed in different parts of the body that it is evident the bacilli must have been carried by the blood, that the meat is rejected as human food. So with milk and other dairy products. Many claim with Nocard that the milk is harmless so long as the udder is quite free from tubercle, and that it is only when tubercle is unmistakably present in that gland that this secretion is to be feared.

Apart altogether from these discussions as to the wholesomeness of uncooked meat and milk, it is safe to say that, up to the present, every writer on the subject holds that even the infecting tuberculous meat and milk is rendered absolutely harmless by cooking. The consensus of professional opinion is tersely given by Salmon and Smith, in their article on tuberculosis in the work on the "Diseases of Cattle," published by the Bureau of Animal Industry: "Fortunately tubercle bacilli are readily destroyed by the temperature of boiling water, and hence both meat and milk are made entirely safe, the former by the various processes of cooking, the latter by boiling for a few minutes."

But this is altogether too narrow a view to take of the subject, and it is liable to lead to most serious and fatal results if put into every-day practice. The professional mind, in concentrating its attention on tuberculous infection, seems to have practically overlooked the no less real, and in many cases no less dangerous, tuberculous poisoning.

To elucidate this matter, let us consider that much of the toxic matter produced by the growth of the tubercle bacillus is retained in Koch's "tuberculin," which has been absolutely sterilized. What, then, is the action of tuberculin on the animal system? It produces a constitutional disorder, with elevation of the body temperature and impairment of most of the bodily functions, notably those of assimilation and secretion. This is abundantly manifested in the wasting and fever of the victim of acute tuberculosis, in which these principles are being constantly produced in large quantities. As the dose is reduced a point is finally reached at which no fever nor appreciable systemic derangement is produced, and thus in many slight and indolent cases of tuberculosis the victim appears to be well, and thus also the usual test dose of tuberculin has no recognizable disturbing influence on the healthy animal system. With any dose less than this it may even be questioned whether it may not be actually beneficial in conferring on the healthy system a small measure of tolerance and power of resistance to the bacillus and its poisons. This, however, is of little account, seeing that no real immunity from tuberculosis is ever acquired. In many systems, both human and brute, the disease continues its slow progress for many years, and the slight tolerance which results, while it may retard the disease so that it assumes an indolent and chronic form, does not fully arrest it.

Very different is the effect of even a minimum dose of tuberculin on a subject which is already attacked with tuberculosis. In such a case the products of the existing tubercle are often so small in amount and the system has acquired such a tolerance of them that there is no manifest disturbance of health, and the animal may even be in excellent condition. But add to this minimum amount of poison already in the system a small quantity of tuberculin, and in a period varying from eight to twenty hours the temperature of the patient's body will rise two or more degrees above the normal, and the destructive process going on in the tuberculous foci will be accelerated.

In cattle this is now employed as an indispensable test of the presence or absence of occult tubercle. In horses and other animals attacked by tuberculosis, tuberculin causes the same rise of temperature, and it may be accepted that the reaction may be thus produced in an animal of any class which is already tuberculous. In the tuberculous man this effect of tuberculin is a well-established fact, and was made the basis of Koch's employment of it as a curative agent. The daily use of tuberculin in cases of lupus or other superficial form of tuberculosis led to a more active congestion and a more speedy molecular death of the tissues in the diseased focus, until such diseased tissues were separated from the living healthy parts, and the progress of tuberculosis in that centre was arrested. If there were no deeper unseen tubercles left in the system, a real cure might be effected in this way. But the cure in such a case was only secured by a temporary aggravation of the disease in its primary focus. If other tubercles existed in internal organs, they too had the morbid process aggravated and extended, and the death of tissue increased by the introduction of tuberculin from without. In such a case the increased mass of tubercle, dead and living, remained confined in the midst of the surrounding tissues, and as the infecting materials could not be cast off and separated from the body, they continued their ravages with an increasing force in proportion to their recent artificial extension.

It is this extension of the tuberculosis under the influence of the toxic products of the bacillus which raises the most important question in connection with the consumption, by man, of the flesh and dairy products of the tuberculous animals, and yet this question has been hitherto left entirely untouched by sanitarians. It has seemed enough for them that the living tubercle bacillus did not exist in the juices of the muscle nor in the milk. It would appear as if it had never occurred to them that all the soluble toxic products of this bacillus were constantly circulating in the blood and plasma that bathed the muscles and mammary glands, and that it escaped into the milk. Yet no pathologist can for a moment doubt this general diffusion of these toxic products.

Accepting, then, as indisputable the presence of the toxins in the flesh and milk, it follows that all who eat of such flesh and milk are continually taking in small doses of tuberculin, and that in case they are already the subjects of tuberculosis, in however slight or indolent a form, this continuous accession of the poison will rouse the morbid process into greater activity and secure a dangerous extension.

If, now, we consider the prevalence of tuberculosis in the human population, and realize that every eighth death is that of a tuberculous person, we see what a fearful risk is being run by the utilization of the meat and milk of animals so affected, even if it could be shown that

[1] Read before the New York State Veterinary Medical Society, January 9, 1894.

as consumed the meat and milk are free from the living bacillus. Such reckless consumption of the products of tuberculous animals can only be looked on as a direct means of sealing the fate of that large proportion of the community which is already slightly affected with tuberculosis.

The claim that the canning of tuberculous carcasses and the boiling or Pasteurizing of milk does away with every element of danger can no longer be entertained. Sterilization is not a restoration to a non-toxic condition, it does away with the possibility of infection, it is true, but it does not render the product innocuous. As a matter of fact, Koch's tuberculin has already been sterilized by heat, but this has not by any means rendered it safe and harmless. On the contrary, it invariably intensifies any existing tuberculous process and develops fever and general constitutional disorder. When tuberculin, therefore, is present in the meat and milk it can only cause these to operate in the same way on subjects that have been already infected.

In my experience with tuberculous cows, cases have come to my knowledge in which invalids drinking the milk of such animals have suffered very obviously, and have improved after such milk has been withheld. So, too, in the case of calves sucking phthisical cows, they have done badly and proved unthrifty though they took the whole of the milk furnished by their respective nurses, and they have thriven better when weaned and put upon solid food alone. I have followed some such calves until they grew up and were slaughtered, and have made post-mortem examinations and found them bearing old calcified tubercles, pointing back to the time when they sucked the infected and poisonous milk.

It is idle to say that such milk was merely lacking in nutritive principles: the calves in question had access to other food while following their nurses, and would not have been harmed by taking the same amount of pure water as they did of milk. Apart from the bacilli, which operate slowly, and which allowed these animals to live for years and even to thrive after they had taken the milk, there was unquestionably in this secretion a definite poison which undermined the health and stimulated the progress of the tubercle. Accessions of bacilli are not denied, but at the worst these acted tardily, and apart from the soluble poisons their action must have been cumulative up to the cessation of the milk-feeding, so that immediately after the withdrawal of the milk the morbid action should have been greater than at any time before this, whereas in the cases in question improvement dated from the change to dry, coarse food.

It may then be held, as proved by analogy, observation, and experiment that the soluble poisons of tuberculosis invariably operate by exaggerating any existing tuberculous process, and that blood and all animal fluids becoming charged with such poisons uniformly tend to endanger the health, or even the life, of any consumer who is affected with tuberculosis.

We may freely allow that the transmission of the bacillus from man to man is far more common than from beast to man. But though the implanted seed may have been in many cases derived from a fellow-man, its subsequent destructive career may be due far more to the constant accessions of the soluble toxic products conveyed in the meat and milk of tuberculous animals. Without these continuous doses of the soluble poisons the implanted germ would in many cases have proved comparatively harmless. Although it could be proved in regard to many cases that the cow had not contributed the seed of the disease, she is left little less responsible for the destructive progress and fatal result. The germ which might have remained comparatively dormant and harmless in the absence of the poisoned meat and milk, is by these stimulated to a more deadly energy.

This hitherto unchallenged factor in the progress of tuberculosis opens up new and uncultivated fields for sanitary work. The great evil ventilated in this paper cannot be effectually met without the eradication of tuberculosis from every herd kept for the supply of food-products for the public. Nothing short of this can be trusted to operate satisfactorily in putting a check upon the present fearful mortality from this disease. No inspection of dressed carcasses, nor of milk, butter, and cheese will furnish a guarantee. We must go to the herds and subject them animal by animal to a critical test, and only accept the products as safe when there is no longer a shadow of suspicion remaining. A professional examination of a most searching kind must be supplemented by the tuberculin test before a clean bill of health can be furnished.

Often when cattle were condemned by the tuberculin test have the owners pronounced them the most thrifty and the least suspected in the herd, and it was only after slaughter, when the bodies were opened and the caseated tubercles exposed, that they were satisfied that no mistake had been made.

Recently in a herd kept for the supply of milk of guaranteed soundness, the stock having been subjected to weekly examinations by a veterinarian, the tuberculin test was applied, and fifty per cent. of the herd demonstrated to be tuberculous.

Without the tuberculin test there is no guarantee possible for the products of the dairy, and the sanitary officers who will affect to deal with this disease in herds without the aid of tuberculin are at best but pruning the tips of the branches of the evil tree. Public money ought not to be thrown away on such fruitless and ineffective work.

The purification of a herd must be followed in every case by a thorough disinfection of contaminated buildings and places, and by a careful seclusion from new sources of infection. It is evident, therefore, that the non-tuberculous herd must be secured against the addition of fresh animals from any herd that has not been similarly attested sound, and that any necessary addition from another source must be tested by tuberculin before it is added to the herd.

Equally important is it to test all farm animals of whatever species which live on the place and cohabit with the herd, and to see to it that no human being suffering from tuberculosis is allowed to attend on the animals or to prepare their food. It is difficult to see how anything short of such a system can afford a guarantee of the absence of the soluble tubercle poisons from our milk, butter, and cheese.

In the case of butcher meats a professional examination when slaughtered, covering all of the viscera as well as the carcass, will be essential, and the current doctrine of sound meat with localized tuberculosis must be abandoned. Every municipality must have its own public abattoir in which alone its meat supplies should be butchered, and where every carcass should be systematically examined as it is opened. Private slaughter houses controlled by individual owners afford endless opportunities for the evasion of sanitary statutes, and ought to be abandoned as relics of an age when modern sanitary science was unknown.

The question of dressed, canned, and salted meats is one that must be carefully considered. It is quite evident that such products must come to us with a sufficient guarantee, if allowed to compete with our own house meats which have passed the municipal inspection. It is equally evident that no inspector paid by the packer or canner can furnish a certificate which will command public confidence. The inspector must be a government official, who is entirely independent of the packers and who is in no way dependent on their good will.

Then again the existing method of furnishing government inspectors at our great packing centres only, and thus giving a monopoly to the large operators, cannot be long maintained in a country of equal rights and privileges. The most obvious cure for this evil is to make all packing-houses government institutions, where the small packer shall have equal privileges with the large, and where all carcasses shall be subjected to the same scrutiny, and all shall be sent out with the same guarantee.

Such a proposition will doubtless be severely criticised from both the medical and economic stand-point.

On the medical side it will be argued that if the toxins in the meat and milk were as injurious as they are represented, we would see the evil results on every side, and that medical men would be universally cognizant of them. And yet do we not see clearly to-day much that was never suspected twenty, thirty, or fifty years ago? How recent is the acceptance by the profession of the doctrine of contagion in tuberculosis, in tetanus, in pneumonia, in influenza, in glanders, etc. Are we to suppose that our forefathers were surrounded by fewer evidences of contagion at a time when no precautions were taken to prevent it, than we are with all the antiseptic and antizymotic provisions of the present day? The facts of contagion were doubtless more abundant in their days than in these, but their attention had never been drawn to them. So now let the attention of physicians and sanitarians be given to the morbid action of the soluble poisons of tubercle, and evidence of their evil results will accumulate on all sides. It is the scrutiny and not the facts that are wanting.

The economist will object to drastic measures for the suppression of tuberculosis on the ground of expense. Who is to pay for the municipal abattoirs, the inspectorships, the disinfections, and the indemnities for slaughtered animals? In return let us ask, Who now pays for the constant losses of live stock which the proposed system would put a stop to? for the frequent infection of sound herds by unfortunate purchases of animals that prove to be tuberculous? for the losses to the nation, the community, and family of the tuberculous one eighth of all deaths? for the loss of work — literary, scientific, manufacturing, commercial, domestic, and manual—of the great host of consumptives waiting all over the land to fill the places of this fatal eighth in coming mortality statistics? for the losses represented by the bills of the physician, nurse, and druggist for these invalids? and for the losses represented by the countless migrations and exiles in search of health, and of the costly consumption hospitals and sanitaria? And who is to pay in the future for the endless harvest of similar fruits, which the seeds now sown through our supineness must inevitably produce in coming generations?

Is it not a truer economy to destroy the seed before it has germinated, or even before it has been sown, than to wait for the multitudinous evils that must attend on its growth and fructification?

Our State Board of Health, which has charge of tuberculosis, not in man only, but in cattle and other animals as well, should take this matter up earnestly. A year ago the Board was very apprehensive of evil results from the use of tuberculin as a means of diagnosis, and only reluctantly allowed me to use the agent, in examinations I made for it, on condition that I would personally bear the full responsibility for all untoward results. This I could afford to do, being well assured from past experience how trustworthy this agent is, and how impossible it is to speedily eradicate tuberculosis from a herd without its aid.

Now that our excellent Board has reached a similar confidence, let me urge it to go a step farther, to accept the logical deduction of its present position, the doctrine of the presence of the toxic products in both meat and milk of the tuberculous animal, and the pathogenic action of these on the infected human consumer. Let our Health Board urge on the Legislature the necessity of providing means for the purification of our dairy herds, and municipal abattoirs where all our meats shall be killed, and where all animals designed for butcher-meat shall be scrutinized by professional government inspectors.

The Hospital Saturday and Sunday Collection amounted a year ago to $58,000; it is hoped this year to bring the amount up to $70,000. There are over thirty hospitals in the association.

AN EXTREME CASE OF LEUCODERMA IN A NEGRO, WITH A COMPARISON OF SIMILAR CONDITIONS IN VARIOUS ANIMALS.

By G. L. MAGRUDER, M.D.,

DEAN, MEDICAL DEPARTMENT, GEORGETOWN UNIVERSITY, WASHINGTON, D. C.,

AND

C. W. STILES, PH.D.,

PROFESSOR OF MEDICAL ZOOLOGY, MEDICAL DEPARTMENT, GEORGETOWN UNIVERSITY, WASHINGTON, D. C.

THOMAS CLEVELAND, the subject of this sketch, has changed from a dark black negro to a uniform white color over his entire body, with the exception of a few spots almost symmetrically distributed over his cheeks and ears, and along the median line of the forehead. There is not a spot of discoloration on any other portion of the body; the soles of the feet, the armpits, and the entire scalp are equally free from pigment. The borders of the patches of pigment that remain are characterized by well-defined concave edges, thus making the edges of the changed skin convex. There is no loss of pigment in the eyes; they still are dark. The photograph gives an excellent representation of his present condition.

He is now over sixty years of age, and has recently come to this city from Georgia. He has affidavits from a number of citizens of that State that he was a black man twenty-five years ago. After careful and patient questioning the following history was obtained: He was born near Washington, and went to Georgia in infancy; his parents were "slick black;" there is no trace of similar loss of pigment in any branch of his family, either before or since his birth, although there is a large number of relatives, including brothers, sisters, nieces, and nephews; he is the father of two children, a daughter and a son; the daughter was born prematurely, about seven months, she was very dark, and died in the first year: the mother received an injury which seriously impaired her health; the son, about thirty years of age, is a stout, healthy man, "black as a crow," has been married twice, and has had black children by each wife.

Tom has always enjoyed exceptionally good health, and has only had some slight sickness in early childhood. At the age of thirteen he used to work in the field bareheaded, and then suffered from headaches, which disappeared as soon as he commenced to wear a straw hat; since then has always been healthy, never had syphilis, and has lived a very temperate life, neither smoking, chewing, nor drinking.

The first evidence of decoloration was a spot near the nipple, which appeared when he was about fifteen; he endeavored to remove it by the use of green walnut juice. The change was at first very slow and gradual. It had not reached his legs "before the war." Fifteen years ago the hands and face were still black, but since that time the progress has been much more rapid, especially the hands. Upon the body and the feet the process occurred in larger areas than on the face and hands, and the discoloration shaded from black to yellow, then to white. On the face and hands there was no shading. There was no difference as to the tactile sensibility of the two colors of skin. The white spots blistered more easily in the sun. The sweat-glands acted very freely, with the characteristic odor of the race.

The hair is still kinky, but has turned gray wherever present. There is a good growth upon the head, but sparse over the rest of the body. There is nothing in the history of this case that will give the slightest clew to the probable cause of this condition.

Upon consulting various works on dermatology and human pathology, it will be found that a certain number of cases are included under the term "atrophic diseases." Although scarcely any two authors agree in their classification of these diseases, we need not enter into a discussion of their general arrangement here, as we are interested in the present paper only in those cases known as "albinism," "vitiligo," and "canities."

Under the term *leucopathia* (achromasia, pigment atrophy) we find cases cited in which the pigment of the skin atrophies or never develops, and these cases are classed as:

1. *Congenital leucopathia*, or albinism, which may be partial or complete; and,

2. *Acquired leucopathia*, vitiligo, or leucoderma.

Under the term *canities* we find included the whitening of the hair. As we wish to compare these conditions with similar conditions in other animals besides the human species, it may be well to give a very brief summary of the conditions as described in various text-books, at the same time citing some of the cases.

Albinism (congenital leucopathia). — 1. *Complete albinism* is usually described as a condition in which the normal pigment is congenitally absent from the skin and eyes, not accompanied, however, by any textural change of the parts in question. It may appear spontaneously, or may be hereditary to a limited degree; cf. Darwin, who cites a case of two brothers marrying two sisters, their first-cousins; no trace of albinism in their antecedents, but all seven children produced from this double marriage were albinos. Formerly it was claimed that albinos were necessarily weak in constitution, but this view is no longer held; hair is fine and silky, white, or slightly yellowish; eyes cannot stand a strong light. Earliest records of albinos came from the Portuguese, who found some "white negroes" (leucœthiopes) in West Africa. Cause unknown, no treatment.

2. *Partial albinism* differs from complete albinism only in degree; eyes not affected; white spots on the skin; hairs growing on these spots are colorless.

Leucoderma (vitiligo, acquired leucopathia) is described as a cutaneous disease in which the pigment of the skin atrophies to a greater or less degree after birth. The white spots generally appear between the ages of ten and thirty, although we find one case (Belcher, 1867) which commenced at five years of age; the patches are non-elevated and have a convex border, the concave border of the surrounding tissue generally being darker than the rest of the skin; in many cases (as in the one under discussion) there is a striking symmetry to be noticed in the appearance of the spots; in other cases the symmetry is more imaginary than real; while one case is recorded (A. Wood, 1871) in which the entire right side of the body turned white, while the left side remained brown. Leucoderma may be—

1. *Progressive*, the spots coalescing and extending slowly or rapidly over nearly the entire body: Bissell, 1817, case of an Indian of the Brotherton tribe, near Clinton, N. Y.; Hall, 1880, case of a negro; the present case, and many others. Or, after reaching a more or less advanced stage, it may remain

2. *Stationary*: a case of this kind is known to the writer. Or in some cases it may be

3. *Regressive*, cf. especially F. T. Wood, 1877, case of a negro, redeposit of pigment in same order in which it was absorbed. In cases of leucoderma the whitened portions of the skin seem to suffer more from intense heat than the darker portions, and Bissell records of his case that there was less perspiration from the white spots than from the dark skin, and that they healed with difficulty when cut.

Geographical and Racial Distribution.—Leucoderma is more common among the darker races than among the lighter ones. In America it is recorded from Canada to Panama, but is said to be much more common in Africa and India. According to Münch, the disease is endemic in Turkestan, where the natives call it Pjes, and believing it to be contagious, they isolate the patients with the lepers. Probably, however, leucoderma in writings of the East is frequently confounded with *lepra maculosa* of the Jews (white Jewish leprosy).

Etiology.—It is quite generally admitted that leucoderma may be brought about in different ways, and T. F. Wood (1882) asks the very pertinent question, whether the cases recorded are examples of different diseases or different manifestations, varying degrees of a process which has a central origin elsewhere than in the skin. The cases thus far recorded may be classed as follows:

1. *Leucoderma syphiliticum*—(cf. Haslund, 1885, Raisz, 1884, Riehl, 1884, Szadek, 1885, Neisser, 1883, *et al.*). In these cases the condition has followed syphilis. A second class of cases may be included under the term:

2. *L. traumaticum.*—These cases, in which white spots follow burns, scalds, and other injuries, are well known to persons who live in districts where there are many negroes. The same condition is frequently found in horses, where the skin or hair may become white at places where pressure is exerted by the harness.

3. *L. parasiticum.*—Some authors state that leucoderma is parasitic in nature, and there would of course be nothing strange if we should find white spots following acariasis.

4. Leucoderma is also said to have followed convalescence from typhoid fever, there being an absorption and gradual redeposit of the pigment.

5. *L. nervosum.*—Cases of leucoderma are recorded as following a severe mental strain. The writer is acquainted with an exquisite case of this kind, in which the patches are small, symmetrical, and confined to the back of the hands.

5. *L. hereditarium.*—Cases are recorded in which heredity seems to have played something of a rôle, although in most cases there seems to be no trace of heredity. Brito (1885) cites the case of a lady in India in whom vitiligo manifested itself in early life, and the same condition appeared in her daughter, in whom it spread much more rapidly. Brito, in writing on the subject of leucoderma in India, states that heredity appears to act as a strong factor, that the condition may be atavistic and may be found in collateral branches.

7. *L. spontaneum.* — Under this head we may include all those cases which appear spontaneously—by which we simply mean that we are unable to recognize the initial cause of the leucoderma. Authors generally dispose of these cases by saying that the change is dependent upon the nervous system, and in support of their

view they quote the change of color in the chameleon and frog. Bissell (1817) remarks: "That it occurs in consequence of a deranged action in the vascular portion of the rete mucosum cannot be doubted." While Startin (1880) states that the cause of the disease seems to be due solely to deficiency of pigment matter in the skin, due to depressed innervation induced by intense cold or heat.

Canities is analogous to leucopathia, the only difference being that the situation of the former is in the hair, of the latter in the skin. It may occur with leucopathia, may be congenital or acquired, partial or complete, progressive or regressive, rapid or gradual in progress, frequently unilateral.

It might be well in this place to refer briefly to the physical phenomena concerned in the color of the skin and hair, and to the position and development of the substances with which this color is connected.

Absorption and Reflection of Rays of Light.—It is a generally accepted fact that the color of vertebrates, as well as invertebrates, is due for the most part to the presence of various quantities of definite pigments in the skin or its appendages. These pigments absorb certain rays of the white light and reflect the others, thus determining the color as it appears to us. If all the rays are absorbed so that none are reflected, the object appears black; if all the rays except the yellow are absorbed, the object appears yellow, etc. It has, however, been shown that other matters besides the mere color of the pigment —such, for instance, as the structure of the feathers in birds—come into play in determining the color of an animal, so that the same pigment need not necessarily give to two different animals exactly the same color; and it is also known that when two animals have the same color, the latter may be produced by two different pigments. A most striking example of this kind is the green in the turacou and the green in the parrot. In the former animal this color is due to a pigment known as turacoverdin, while in the parrot "the actual pigment is yellow." Although Gaskell claims that a white pigment is found in the pineal eye of the lamprey and the same is claimed for certain butterflies (*Arge galathea*), it is quite generally denied that any white pigment exists in animals; and authors claim that the white appearance of an animal is due entirely to the irregular reflection of all the rays (none being absorbed) in different directions. In the same way that the whiteness of snow is explained by the presence, between the crystals, of minute globules of air which reflect the light irregularly in different directions, the whiteness of hair is explained by the presence of minute globules of gas in the hair.

We should also mention that the organs immediately below the skin play an important rôle in determining the color of an animal.

Position and Origin of the Pigment.—In the skin of mammals the pigment is situated in ectodermal tissue, for it is in the lowest layer of the epidermis, that is, in the cells of the basal layer of the stratum Malpighii. In the hair, which is also ectodermal, it is situated in the core. Although found in ectodermal tissue, it is quite generally admitted that it is of mesenchymal origin—Kodis (1891) alone opposing this view and claiming that the pigment is ectodermal in origin. In the last edition of Wiedersheim's "Grundriss" it is described as an excretory product, a degeneration product of the red blood-corpuscles carried by leucocytes from the corium into the epidermis. As a matter of comparison, it is interesting to note that in fish the pigment-cells are in some cases in both the epidermis and cutis, in others only in one of these layers, while in amphibia the pigment is chiefly in the cutis, partially diffuse, partially in cells.

Variation in Color.—In passing now to conditions in animals, similar to those described above, we cannot hope to recite all the facts known about color and coloration, as that would take a number of volumes, but we will do well to cite some of the better known examples of variation in color. To begin with, a study of animals convinces us that there is scarcely any character which is so variable in species as that of color—a fact which is particularly true of the domesticated animals. In many cases it is absolutely impossible to establish a theoretical standard color for a species. Who would, for instance, try to establish a norm in color for the (conglomerate) species *Canis familiaris*, the domestic dog. Scarcely any two specimens, even of the same breed, agree exactly in color, and the same is true of cats, horses, cattle, pigeons, chickens, etc. In Man we find this same individual variation in color, not only when we compare an individual of one race with one of another, but when we compare individuals of the same race. Even among the brothers and sisters of one family, we may find an extreme blond and an extreme brunette. It is claimed that among the non-domesticated animals we do not find this same extent of variation, a claim which to a certain degree is supported, but in some respects is erroneous. In the adult of the Fall Web worm (*Hyphantria cunea*) we find all possible gradations from a perfect white to a form whose wings are nearly half black; in the Gooseberry Geometrid (*Abraxas grossulariata*) every possible variation between a black and a white is found; enormous variation exists among the Mollusca; and among the higher animals, from fish to mammals, we find an individual variation in color. In many cases, more especially among mammals, the color of a species is apparently quite constant, but if a large number of forms are examined from different localities, it is always possible to detect some individual variation in color or coloration.

Besides the individual variation in the shade of color, generally determined, as we have seen above, by the character and amount of pigment present, we find a variation in the color of the different parts of the body. For instance, the ventral surface of an animal, especially of a vertebrate, is almost always lighter than the dorsal surface. In some cases the ventral surface is even white, while the dorsal surface may be very dark, a fact which is explained differently by different authors—some claiming that the ventral surface is less exposed to light than the dorsal surface, and that the light, or absence of light, affects the color; while others hold that the dark color on the back of animals is of great service to them in extreme heat, and has hence been increased by natural selection. That light in some cases probably does influence pigmentation, is shown by the interesting experiments of Cunningham (1891), who placed some young flounders in a tank provided with a mirror on the bottom, and noticed after a time that the under surface, which is generally white, had in many cases become more or less pigmented. An interesting case in point is furnished by those insects whose pupal stage is concealed (under the ground, for instance), these being darker than those whose pupæ are exposed.

Animals generally undergo some change of color during their lifetime, and this change may be sudden and more or less frequent, as in the case of the chameleon, frogs, many fish, or it may be a gradual change as they grow older, or a change at certain periods of the year, a change during sexual activity, etc.

It is a well-known fact that chameleons, frogs, and many other animals become dark when on a dark background, and light when on a light background; in many of these cases it seems that the chromatophores, or pigment bearing cells, are under the influence of the nervous system. It is believed that the color of the background stimulates the eye, and that the impulse acting through the nervous system causes the change of color. A dark light would stimulate the eye but slightly, and there would be no contraction of the chromatophores, so that the animal would remain dark; a bright light, however, would stimulate the eye more strongly, a stronger impulse would be transmitted to the chromatophores and would cause them to contract, so that the animal would become lighter in color. An interesting fact is that blind frogs and blind fish have lost their power of changing color, a fact which it is difficult to harmonize with

Steinach's recent results, that in the case of amphibia the light does not affect the chromatophores through the eyes, but acts directly upon the cells and causes a contraction.

As examples of the changes of color during the development of the individual, numerous instances could be cited, but we will confine ourselves to the following, drawn from various sources:

The children of the Australians are a yellowish-brown directly after birth, and become dark at a later age. Those of the Guaranys, of Paraguay, are whitish-yellow, but they acquire the yellowish-brown tint of their parents in the course of a few weeks. The African babe is a reddish nut brown, which soon becomes a slaty gray, the black color being fully developed within a year in the Soudan, and within three years in Egypt. Darwin, from whom we have taken these statements, also records that the Himalayans (a breed of rabbits) are quite white, and true albinoes, or more rarely a pale gray, when first born; in a few months, however, they gradually assume their dark ears, nose, feet, and tail. It will be noticed that in all these cases the animals are born light and turn dark (melanism in a greater or lesser degree!). In the silver-grays and chinchillas (two other breeds of rabbits) the young are born perfectly black, but soon assume their gray or silver tints (acquired leucopathia, *i.e.*, canities and leucoderma!). The same is true in the case of gray horses, which are nearly black when foals, and become grayer and whiter as they grow older. Exceptions in the case of the rabbits cited above, are, however, not unknown, and to this we wish to draw especial attention; *i.e.*, the Himalayans sometimes produce a single black young in a litter, which, however, becomes perfectly white within two months' time, and silver-grays are sometimes born a cream-color, but they ultimately become black.

In the changes of color at certain seasons, the winter coat may be lighter or darker in color, according to the species; *Cervus mantchuricus* and *C. durancelli*, and the snow-bunting, are darker in the winter than in the summer. Seasonal changes have been noticed in grasshoppers and beetles. Among Arctic animals, the musk-ox, glutton, and raven undergo no change at the approach of winter; the reindeer becomes gray; the Hudson Bay lemming (*Cuniculus torquatus*), the American hare (*Lepus americanus*), the ermine, and many others become white at the approach of winter; the Arctic fox (*Canis lagopus*), generally becomes white in some localities, but in others it usually remains dark. The same remark applies to the Alpine hare.

This change from a dark to a light color has been brought about artificially by Sir J. Ross, who records that a Hudson Bay lemming (*Lepus torquatus*) had retained its summer color when kept during the winter in a warm cabin. One day, however, it was placed on deck, and within a day, when exposed to a temperature of — 30° F., "the fur on the cheeks and a patch on each shoulder had become perfectly white," and within a week the animal was almost entirely white. An exceedingly interesting fact in connection with this experiment is that the hairs which turned white grew rapidly in length, and that only the tips were involved in the change. In the case of *Lepus americanus*, F. H. Welch has shown that when the winter change takes place there is not only a change in the color of the autumnal hairs (in October), but a new growth of white winter hairs (in November); and Poulton, from whom we have taken many of the examples here cited, in discussing this subject remarks that it is probable that the new winter hairs do not contain any pigment but that in the summer hairs which do contain pigment, the latter does not have any effect in determining the color on account of the great amount of gas present. He also explains those cases of canities in man in which the hair has changed during some nervous attack but darkened afterward, by assuming a sudden evolution of gas in the hair and its subsequent absorption, thus leaving the hair its original color.

In the case of those animals which remain on the snow nearly the entire year, as the Arctic bear, the white color has become constant; but this must be an acquired condition for the races, for some of these animals at least (*Lepus glacialis*, for example), are born a darker color (gray, in this case), and change to white on the approach of the first winter.

It is interesting to note that while we find a tendency toward white in mammals and birds as we approach colder climates, in insects the tendency of color is toward a black or brown.

Many other cases of change in coloration might be referred to, but in order to avoid taking up too much space with examples of this kind, we will content ourselves with the cases already cited, and refer the reader who may desire to follow the matter further to Poulton's "The Color of Animals" (1890), Beddard's "Animal Coloration" (1892), Deane in "Bul. Nuttall Ornithological Club," 1876 and 1879 (eighty seven cases of albinism and six cases of melanism among North American birds), and to Darwin's various works. In connection with albinism among birds, however, it should be remarked that this term is used in a very broad sense by ornithologists, referring not only to complete congenital achromatia, as reported in some white blackbirds, but also to partial congenital or acquired achromatia.

When we seek a cause for these differences and changes in color and coloration, we have no easy task before us. Some cases are evidently due to the nature of the food, others to temperature; some, it is claimed, are due to moisture, many to natural selection, and others to some more or less hypothetical influence of the nervous system; but whatever the cause may be, we always find an individual variation in the various specimens. The question, therefore, naturally arises as to whether we should include albinism, *all* cases of leucoderma and ascities among the diseases, or whether many of them cannot be looked upon as cases of extreme individual variation or, if one prefers the term, as freaks. The answer to this query depends entirely upon our definition of a "disease." If, with the ante-Darwinian idea of the fixity of the species before us, we look upon everything which does not correspond to our idea of the norm as pathological and diseased, then the question is easily answered in favor of looking upon all cases of achromatia as pathological. But if we take into consideration the utter impossibility of establishing a theoretical norm in man; if we recall that there is really no sharp line to be drawn between complete albinism, partial albinism, and leucoderma; if, further, we remember that all of these stages find their parallels as racial or specific characters in certain species and races of animals, we will certainly hesitate before pronouncing Uncle Tom Cleveland and similar cases, in which no trace of disease is found, as pathological specimens! If, however, we insist upon calling Tom a *diseased man*, and true albinoes *diseased beings*, must we not be consistent and call the albino rabbits, mice, rats, and ferrets, as well as the Himalayans, silver-grays, and chinchillas *diseased varieties*, and the exceptional congenitally black Himalayan and the cream-color silver gray as diseased individuals belonging to *diseased varieties?* How would it be with a cross between an albino rabbit and a gray rabbit which should happen to be partially white and partially gray? If we carried our ante-Darwinian theory to its logical conclusion, we should discover that everyone of us—especially of the white race—is diseased! How would matters stand with the domesticated pigeon? Should we call every breed and every individual differing from its ancestor, the rock-pigeon (*Columba livia*), a pathological breed or specimen, or should we look upon these breeds as varieties resulting from individual variation, or shall we combine the two ideas in one and accept the inevitable conclusion that all individual variation is pathological? What shall we do with those cases in which the males and females are similar when young, but whose males take an entirely different character upon becoming mature? Are they pathological?

It is true that in many of the cases here cited, the change in color is racial as well as individual; but that the change began as an individual variation is made almost certain by the ontogeny of the animals, by the extreme individual variation in many of the cases, and by a comparison with allied forms; and on this account we have the right to bring the races in question into our discussion.

Having advanced these suggestions in connection with this case of leucoderma, and having cited a number of examples of color and coloration in the animal kingdom, we will, without carrying the discussion further, sum up our views upon this subject as follows:

1. It is exceedingly difficult to draw a sharp line between individual variation and pathological lesions.

2. Many cases ascribed to pathology—as albinism, partial or complete, and some of the cases of leucoderma and canities—can equally well (and probably better) be looked upon as cases of extreme variation of the species.

3. Man should be looked upon as an animal under domestication, and we must accordingly be prepared to find an immense variation among the races and individuals.

4. Albinism, both partial and complete, leucoderma, and canities of man, all have their parallels among other domesticated and wild animals, in many of which they have become racial or even specific characters.

5. These characters must, however, have begun as individual variations, and there is no reason to doubt that if systematic breeding experiments were kept up for a sufficiently long period, with albinoes or leucoderms, or if these characters came into play in natural or sexual selection, races of albinoes or leucoderms in the human species could be established.

A PLEA AGAINST ACCOUCHEMENT FORCÉ IN THE TREATMENT OF PLACENTA PRÆVIA.

By JULIUS ROSENBERG, M.D.,

LECTURER ON OBSTETRICS IN THE NEW YORK POLYCLINIC; ATTENDING PHYSICIAN TO THE MOTHERS' AND BABIES' HOSPITAL.

THERE is of late a tendency to displace the tried and conservative treatment of placenta prævia by more radical and aggressive methods. Instead of arresting the hemorrhage by rupturing the membranes, tamponing of the vagina, or podalic version, according to the conditions found, it is considered good treatment to dilate the cervix with instruments or the fingers, and to empty the uterus with the greatest possible speed.

I doubt not that in the hands of a few exceptionally skilful men this treatment is often successful, but I do not hesitate to place myself on record in believing that its universal adoption will lead to the most deplorable results. The improvement in the methods of arresting post-partum hemorrhage, and the trust which is placed in antiseptic precautions, have made men bold and aggressive. Everything is now considered possible. The slow labor of old primapara is no longer slow, it is treated surgically. The cervix and vagina are dilated with the knife, and the unsuspecting child is rapidly dragged into existence.

Ultra-conservatism has given place to radicalism. The pendulum has swung from temporizing to the other extreme.

Symphyseotomy has been revived, and spreads like the whirlwind over the country. Everyone desires to do this operation, in spite of a mortality of about twelve per cent. and other consequences not mentioned in the glowing reports of successful operations.

I do not wish to belittle the glorious advances made in the obstetric art. I am opposed to hesitating and procrastinating methods if rapid and decisive action is clearly indicated. Should radical treatment give better results, then away with conservatism; it is obsolete and harmful. But I deny that the accouchement forcé is a superior method, even in the most skilful hands, to the treatment hitherto employed in placenta prævia; its great dangers in this complication must be obvious to all.

Although I have not a long list of cases to report, I believe it my duty to publish these few cases, carefully observed, in both hospital and private practice. They will serve to illustrate that the conservative methods are free from the dangers which necessarily accompany the rapid emptying of the uterus.

What are the best methods of treatment in placenta prævia? The Braxton-Hicks method of version serves admirably in many cases. If the cervix admits two fingers and the child is movable above the brim, version may be performed and the bleeding surface compressed by the breech. Then the case must be left to nature. Should the bleeding continue, traction upon the foot ought to be made. The child thus left in utero will frequently perish (I believe the mortality is about sixty per cent.), but we should beware, lest we be tempted to resort to rapid extraction. Besides the threatening post-partum hemorrhage, there is the danger from cervical lacerations. The branches of the uterine artery are enormously dilated in placenta prævia. The succulent cervical tissues tear easily, and a fatal hemorrhage may follow the hasty delivery of the child.

The following cases are to the point:

CASE I. (Observed in the Dresden Maternity.)—A X.-para, aged forty-three, was brought to the hospital in a condition bordering on collapse. She had bled very profusely. The doctor who had attended her at home had tamponed the vagina. The pelvis was normal. The child in left occiput anterior position. Head movable. The os admits three fingers. Placenta prævia centralis. As the woman was flooding, the Braxton-Hicks method of version was immediately performed. It was not necessary to perforate the placenta, all hemorrhage ceased as soon as the breech was fixed in the lower uterine segment. Three hours later, when the os had fully dilated, a dead child was easily extracted. The woman left the hospital on the thirteenth day.

CASE II.—V.-para, aged thirty-six. I was called by a midwife to see a woman who was flooding. The child was in L. O. A. position; the head movable above the brim. Slight labor pains. The os admitted three fingers. A piece of placenta could be felt in the cervix. I performed bi-manual version, ruptured the membranes, and brought down a foot. All bleeding ceased. I then left the further progress of the case to nature. There was slight bleeding at times, which was stopped by traction upon the foot. After waiting two hours, a healthy living boy was born. There was no further hemorrhage, and the woman passed through a normal puerperium.

CASE III.—VI.-para, aged thirty-four. I was called to see a woman who had been in labor twelve hours and was bleeding. I found a child in L. O. A. position. The os was dilated to the size of a silver dollar, a piece of placental tissue could be felt on its right margin. The membranes were yet intact, but bi-manual version was quite difficult, because the head was not very movable. I finally succeeded in bringing down the right foot. Two hours later an asphyxiated child was delivered, which I was able to resuscitate. There was no hemorrhage after the version. The puerperium was normal.

CASE IV. (Dresden Maternity.)—VI.-para, aged thirty-six. Normal pelvis; child in R. O. A. position. The patient had slight vaginal hemorrhage for several days, which was always arrested through vaginal tampons. Her brother, who is a physician, suspecting placenta prævia, insisted upon her going to a hospital.

When the patient was admitted, the os was dilated a little more than a silver dollar. The margins of the cervix were thick. Lateral placenta prævia. As the patient was again bleeding, podalic version was performed, succeeded by the immediate extraction of a living child. A very severe hemorrhage followed the delivery. The

uterus well contracted; therefore the hemorrhage was due to cervical lacerations. The cervix was seized with volsellum forceps, brought into view, and the bleeding vessels were rapidly ligated; the whole manipulation certainly taking not more than two minutes. But the loss of blood had been enormous; the patient did not rally from the collapse in spite of active stimulation and saline infusions. She died two hours post-partum.

It is my firm belief that this unfortunate woman would have been saved if, after the performance of version, the case had been left to nature. The child might have perished, but what is a child's life compared to that of a mother?

In many cases the simple rupture of the membranes suffices. It is indicated if the presenting part has entered or will easily enter the lower uterine segment. Should the bleeding stop, the case must be left alone. If the hemorrhage continues, a firm vaginal tampon will compress the bleeding surface against the fixed head. In cases in which the cervix is fully dilated we may proceed to immediate delivery.

Case V. (Dresden Maternity.)—II.-para, aged twenty-seven; in the seventh month of gestation. Was brought to the hospital bleeding freely. Pelvis normal, vertex presentation. Head had entered the pelvis, os nearly fully dilated. Placenta prævia lateralis. Upon rupturing the membranes, the head descended and the hemorrhage ceased. The case was left to nature. The birth of the child followed thirty minutes after the rupture of the membranes. Patient left the hospital on the ninth day.

Case VI. (Dresden Maternity.)—I.-para, aged twenty-one. Normal pelvis; os fully dilated; child in L. O. A. position; membranes intact; marginal placenta prævia. Hemorrhage ceased upon rupturing the membranes. Thirty minutes later a living child was born. The patient left the hospital on the tenth day.

Case VII. (Dresden Maternity.)—XXI.-para, aged forty-three; vertex presentation. Patient was brought to the hospital in an extremely anæmic condition. Radial pulse barely perceptible. Marginal placenta prævia; os fully dilated. The rupture of the membranes was succeeded by the rapid expulsion of a dead child. Patient left the hospital on the tenth day.

Case VIII.—III.-para in the seventh month of pregnancy. Dr. H. G. Locke kindly asked me to see this patient with him. She had been flooding for several hours. The child was in breech presentation. The os admitted one finger. A large piece of placenta occupied the cervix. She was in fairly good condition, the bleeding had almost ceased. Labor pains were frequent. An hour later the flooding became again profuse, and as the os was now fully dilated I ruptured the membranes. The breech immediately descended and a living, but premature, child was easily delivered. No further hemorrhage.

Here I report seven cases of placenta prævia without a single mishap. The eighth would also have recovered, if, after the version had been performed, the woman had been left alone. Under this conservative mode of treatment, the mortality in the large lying-in hospitals of Germany is about four per cent. Better results can certainly not be expected from the accouchement forcé. The accouchement forcé necessitates the prolonged and repeated introduction of the hand into the uterus. This increases the dangers from puerperal fever, shock, and air-embolism. Have we a right to subject our patients to these added dangers?

After all, what are the advantages of the accouchement forcé in placenta prævia? In what particular point is it superior to other methods? The hemorrhage we can control through version, the vaginal tampon, or the rupture of the membranes. The dangers to the child are not diminished. That it is a more rapid method I will grant, but this plea hardly justifies such a hazardous operation.

I am not opposed to the accouchement forcé. In desperate cases of eclampsia and accidental hemorrhage, it is always a legitimate operation, often absolutely demanded. But we must hesitate before resorting to it in placenta prævia, a complication in which it is exceptionally dangerous, and where other and better measures are at our disposal.

109 East Seventy-first Street.

A NEW METHOD OF ADMINISTERING CREOSOTE.[1]

By REYNOLD W. WILCOX, M.D., LL.D.,

New York.

Professor of Clinical Medicine and Therapeutics at the New York Post-Graduate Medical School and Hospital; Attending Physician to St. Mark's Hospital.

At the present time most clinicians are in accord in believing that creosote is a most valuable remedy for pulmonary tuberculosis. That it is a specific probably no one claims, but that of all remedies it gives the fewest disappointments we will admit. The literature is extensive; a bibliography to 1893, by no means complete, records more than two hundred authors of a far larger number of papers. From the time of its discovery and use by Reichenbach, in 1833, until it passed out of vogue in 1853, there was ample evidence of its value if we may so infer from the papers of Grandjean, Breschet, and Bertholet, Mignet and Wolf, 1834; Cless and Cortoni, 1835; Pétrequin, Martin-Solon, and Koebler, 1836; Rampold, 1837; Inmann, 1851; Verbeck and Debout, 1852. That it fell into disuse was believed to be from the presence of impurities and the practice of administering too small a dose. Since Bouchard and Gimbert reintroduced the drug, in 1877, the principal question has been how to introduce the drug into the organism in sufficiently large quantities, for it is a well-known fact that a daily dosage of three drachms, and usually far less, when administered by the stomach, gives rise to untoward, even poisonous, symptoms. Bourget proved that on those parts where creosote capsules were dissolved, local circumscribed inflammations were produced. Of the earlier literature after its revival, the most important papers are by Sommerbrodt, Fraentzel, Reuss, Pick, Guttmann, Horner, Lublinsky, and Robinson, in 1878. My own use of this remedy is coextensive with the entire time of my practice of medicine. That the administration by way of the stomach has been found insufficient is shown by the various substitutes proposed: Rectum, Bourget, 1889; subcutaneously, Du Castel, 1882; frictions, Bourget, 1889; by way of the respiratory passages—inhalations—Labbée, 1879; laryngeal applications, Cadier, 1878; intra-tracheal injections, Beehag, 1888; intra-pulmonary injections, Lépine and Truc, 1885. By subcutaneous injection excellent results have been obtained, but this method presents many inconveniences; it requires much time, it necessitates a special and expensive apparatus, it is hardly to be employed except in hospitals, so that in spite of the excellent paper of Gimbert, in 1891, this method has attracted but little attention. In 1893 Audeoud presented a carefully written monograph upon the use of the rectum as the channel for the administration of the drug. This method also yielded good results, but its inconveniences are very considerable, and it is doubtful if it will be a practicable method for the physician. It has been sought to overcome the defects of creosote by the substitution of various preparations of the remedy. Such modifications have been made by Valzer (guaiacol benzoate), by Haas (cinnamic ether of guaiacol, which has been called styracol), by Giacosa (carbonic ether of guaiacol), by Hölscher and Seifert (carbonate of guaiacol), and finally by various physicians, guaiacol. Good beechwood creosote contains from sixty to ninety per cent. of guaiacol. My own experience has been that guaiacol, in dose proportionate to its percentage in creosote, is by no means efficient in pulmonary tuberculosis; even in equal dose I have not found it to be of the same value as the crude drug. So that the general opinion seems to be

[1] Read before the Lenox Medical Society, February 12, 1894.

that it is the beech-wood creosote, the complex body, which possesses the greatest value. We believe, as does Sommerbrodt, that the more of the drug the patient can bear without injury, the more benefit will he derive, and the sooner will the tubercular process be controlled. Hitherto I have been most successful in the use of it in the form of enteric pills, *i.e.*, pills made up with paraffin or ones coated with keratin. In some cases I have used in addition the mixture of creosote, alcohol, and chloroform (Robinson) for inhalation. Even with enteric pills, gastric irritation, backache, and malaise are not unknown. The use of creosote in soluble capsules with cod-liver oil, as was so strongly recommended by Sommerbrodt, I have long since abandoned on account of the nauseous eructations of the oil. In spite of all its disadvantages I have adhered to the use of creosote, for the five thousand cases of Sommerbrodt (1887) to which he has recently added his later experience, and the seventeen hundred of Von Brunn (1888) are too strong evidence to be lightly set aside. In spite of the many cases where toxic symptoms, even alarming ones, have arisen, and the recently reported case of Freudenthal is an example, I believe we are justified in continuing to use this remedy although we do not attribute to it any anti-bacillary properties. Notwithstanding that it is probably useless in acute tuberculosis, in tubercular pleuritis and enteritis, and that it is contra-indicated in acute and chronic nephritis, and in certain cases of idiosyncrasy, there is an ample field for its employment. Several years ago the carbonate of creosote, that is, beech-wood creosote (ninety-two per cent.) in chemical combination with carbonic acid (eight per cent.) was discovered in the scientific laboratory of Dr. F. von Heyden's successors at Radebeul, near Dresden, who have named it creosotal. As you see from the specimen, it is a clear, pale, almost colorless liquid of sirupy consistency, becoming thinner by heat. It is insoluble in water, but soluble in alcohol or in four to five parts of cod-liver or olive oil. It has a slight odor of creosote, and an oily, slightly tarry taste, which is in marked contrast to the burning taste of creosote. It can be administered clear, or, as it is said—but of this I have had no personal experience—by hypodermic injection, the precautions being taken to use a large needle, and to reduce the consistency of the liquid by heat. It can also be administered in the form of an emulsion, one half to two drachms being beaten up with the yolk of an egg, diluted with water, and flavored with any aromatic sirup. During the past three months I have found the administration by means of gelatine capsules, either hard or soft, from ten to twenty minims in each one, to be eminently satisfactory. There is no doubt about the elimination of creosote carbonate by the respiratory tract—the breath gives ample evidence. It is also excreted by the urine, although in what proportion it is at present impossible to state, for the estimations have not been made. Two drachms per day, even on the first day, may cause the urine to become dark green. So far as I know, this is the only symptom to which it gives rise, and it is simply an indication to diminish the dose to one half of its former size. According to my observations it does not produce malaise, nor irritation of stomach or of intestines. It is stated that it does not produce any diarrhœa, and also that if a diarrhœa exist, it is without effect upon it. The first part of this statement I believe to be correct, the latter I have not had an opportunity to verify. We have no doubt as to the fact that it is non poisonous; the important question is, Is it as efficacious as creosote? Chaumier used it in eight cases with equal success so far as the lesions were concerned. My own observations confirm his. Since the creosote carbonate contains ninety per cent. of creosote, the dose may be considered to be practically identical. Fifteen to twenty drops per day is probably sufficient for children; adults will bear one to two drachms, even four drachms per day in divided doses may not be excessive.

706 Madison Avenue, February 1, 1894

THE ROCKY MOUNTAIN REGION, ESPECIALLY NEW MEXICO.

By FRANCIS W. GALLAGHER, M.D.,

EL PASO, TEX.

To the invalid whose hope for health is in change of air and scene, and to the physician whose duty it may be to direct him to that locality where his chances of recovery will be greatest, the subject of climate must ever be of the first importance. While weather charts and weather statistics may serve a useful purpose in the libraries which will go down to future generations to give some imaginable idea of the climatic conditions under which their fathers lived—serving to show that the mean annual temperature at some locality, between a polar cold for some part of the year and a torrid heat for some other part, was a delightful medium which never really did exist at that locality except in the happy blending of the averages of figures; while I say they may be useful for this purpose, they are but rudimentary means of obtaining useful information, not only as to the climatic influences which exist at any given point, but also as to the value of those conditions applied to any particular case of disease. When a patient with tuberculosis is sent from sea-level and the damp clayey soils where his disease had its beginning, to almost anywhere in the Rocky Mountain region, and he continues to have the good care and treatment we will hope he received at home, his chances for recovery under the new surroundings are vastly improved. Still this indefinite advice to seek the mountain country is not sufficient, and the time must come when intelligent direction will be given to the district (I do not use this word in a limited sense, as applying to city or town) where the possibilities for him are the greatest; for it is important to bear in mind that consumption is a dread enemy with whom there can be no compromise, for here truly the wages of imprudence is death, and the most vigilant are oftentimes overcome. Having arrived in the mountain country, to then ascertain the locality best suited to his crippled physical needs, the patient, at great expense and inconvenience of travel, must largely determine for himself after he has found the weather chart and fund of information, derived from articles of special pleading, a delusion and a snare. To the invalid of means this is not so serious a matter; in fact, the constant change of scene and environment may be conducive to a healthy stimulation of the weakened constitution, but to the unfortunate weighed down by disease, unable to work, and with only a limited store to help him through months of weary struggle back to health, the knowledge of the lean and shrinking pocketbook is often the very potent factor producing a state of mind antagonistic to his physical well-being, and the weight in the balance which carries him in an unequal struggle to the grave. I have not undertaken this article with the design of equalling much which has been written on the subject of climate for the consumptive, but with the hope that I may be able to add some little to the general fund of information on the subject, derived from a residence of nearly four years along the Rockys of Colorado and New Mexico, and from the personal effects of this region on pulmonary tuberculosis, and also with the further hope that it may be the means of directing the increased attention of the profession to the Territories of New Mexico and Arizona, as affording to the consumptive a more genial and health-giving climate for portions of the year than the more northern mountain country. My shifting residence during this time has extended from Denver on the north to El Paso on the south, and west into the Territory of Arizona. The conditions best suited to the improvement of the tuberculous patient vary with his idiosyncrasies and the progress the disease has made, and somewhat also on the form the disease has taken on. However, it has become almost axiomatic with those who have had the largest opportunities for observing results, that a dry air, sunshine in abundance, and some elevation above sea-level, are some of the climatic essentials in the treatment of pulmonary consumption in any form. No-

where in the United States are these essentials found as in that expanse of territory embracing Colorado, New Mexico, and Arizona. Patients in the early stages of phthisis, or those with the pretubercular state, will make no mistake in selecting a home almost anywhere within those bounds. There is, however, another class, on whom the disease has already made marked headway, and who have inherited a constitution which poorly withstands the shock of the ice-laden, bitter winds, and low temperature of portions of this region. Such patients, if blessed with abundant means, may be the privileged possessors of just such climate as suits each mood, for within this extent of territory may be found, in the procession of the seasons, every degree of luxurious, and at the same time health-giving, climate the most captious might desire. During June and July he will find somewhere in Colorado every wish as to climate gratified; during August, September, and October, he will, in Northern New Mexico, find the Mecca of his desires; during October and November, through Central New Mexico and Northern Arizona, he may breathe the balsamic laden air from pine-covered hills and bask in the sunshine of an absolutely cloudless sky; during December, January, February, and March he will find in Southern New Mexico and Southern Arizona a climate so genial that no cause for complaint can be found; and finally, during April and May, he will find in all that country in Southern New Mexico and adjacent territory, extending one hundred miles north of the boundary of Old Mexico, a land of perpetual sunshine, free from the now too ardent rays of the Arizona sun and the chill which comes from the snow-capped mountains of Colorado. Physicians resident in this mountain country, oftentimes with no intention to misstate the facts, but inspired, doubtless, by that sentiment which Scott glorifies:

> "Breathes there the man, with soul so dead,
> Who never to himself hath said,
> This is my own, my native land!"

are unconsciously influenced in their public writings by a loyalty and love for home which conceals the whole truth in regard to that special spot of ground of which they write. Colorado, for instance, deserves every kind word which has ever been written of her by doting sons; thousands of people owe restoration to health, to friends and family to her kindly care. She was the pioneer in the blessings which the Rocky Mountain region is dispensing with lavish generosity to the afflicted who seek its valleys and mountain sides for health. For years she alone constituted the "Rocky Mountain Region," and when her newer-born sisters to the south, in their good time, by their alluring claims to the consideration of the invalid, began to catch the overflow from her teeming health-resorts, and from responsive hearts began to go forth the glad acclaim, "A new land of promise found," her doting sons, many of whom found not only health but wealth within her borders, and jealous of divided honors with their queen of States, rallied in her honor, and through medical and secular press cried out and still cry out: "There is no other land whose sun is half so bright, whose skies are half so blue." While we admire the loyalty of this spirit, let us remember too that the mission of the medical profession knows no geographical lines, and that what it seeks is the greatest good of each who looks to it for help, and when conditions favorable or unfavorable are found, it is its duty to so proclaim for good or ill. That there is no part of Colorado which for the entire year is best suited to the majority of delicate and impressionable consumptives, while the disease is still in its active stage, I think all who are acquainted with the facts, and who do not allow their devotion to home to bias their opinions, will admit. During interrupted portions of the winter, at the most noted of the Colorado health-resorts, the weather is beautiful and everything to be desired, but following a week of such weather at either Colorado Springs or Denver, may come another week which will rival a small arctic circle and interdict, for the invalid, any attempt at out door life. During the October and November of 1892, for instance, I walked at Colorado Springs in damp and chilly air, through slush and melting snow, and in Denver for days preceding Christmas the weather was bitterly cold, with an ice-laden wind and a thermometer ranging often, in the mornings, many degrees below zero. Rubber boots and gossamers were at a premium when they were not replaced by arctic shoes and fur coats. In both cities I conversed with physicians who, under stress of prevailing circumstances, sarcastically commented on the character of those "health-resorts." Northern New Mexico, at an altitude of six thousand feet and higher, is also cold, and has snow in abundance. I have seen more than a foot of snow on the level, remaining on the ground for a week and more, at an altitude of seven thousand feet, at this same time of year; but in New Mexico one never experiences the bitter driving winds occasionally felt at Denver and vicinity. In fact, after having crossed the Raton range, which one does at an altitude of seventy six hundred feet by the Santa Fé Railroad, and which at this point is the boundary line between Colorado on the north and New Mexico on the south, he seems to have left behind him the essence of the northern winter, that piercing cruel wind, the blizzard, to which only the heartiest constitutions can react. In conclusion, then, I would address the profession in behalf of that large class of invalids who are forced to make some one section their home while awaiting the health-giving touch of kind mother nature, and in their interests I would say that, for a home for the twelve months of the year, no portion of the territory comprised in the country known as "The Rocky Mountain Region" is at all comparable to New Mexico. Over her whole territory is found a zenith almost perpetually cloudless. The atmosphere is dryer than in any other part of the Union, excepting portions of Arizona, and within her boundaries any altitude from three thousand to ten thousand feet may be found. To those who may wish to enjoy some winter weather, Northern New Mexico will afford that natural seasonal change they desire, while for others who are willing to endure a little hotter summer than they would otherwise care for, to secure for themselves a winter which is a continued and delightful spring, the southern portion of the Territory will answer every demand; and between these two geographical extremes, comprising a line from north to south of more than three hundred and fifty miles, and with variations of altitude within the limits named above, one may find a number of modifications of the two examples given. The possibilities of New Mexico for the seekers after health are yet largely unrecognized, and time will win for her a crown as bright as her never-failing sun.

REPORT OF A CASE OF IMPERFORATE HYMEN WITH THE RETENTION OF MENSTRUAL BLOOD—TOGETHER WITH REMARKS UPON THE QUESTION OF THE PHYSICAL EXAMINATION OF YOUNG GIRLS.

By CHARLES P. NOBLE, M.D.,

PHILADELPHIA, PA.

SURGEON-IN-CHIEF OF THE KENSINGTON HOSPITAL FOR WOMEN, PHILADELPHIA.

THE case which I will report herewith is of interest not only because of its comparative rarity, but also because of the lesson which it teaches with reference to the necessity of using good judgment in deciding whether to make a local examination in the case of young unmarried women who are complaining of symptoms referable to the sexual organs.

Mary S——, aged fifteen, of Bucks County, Pa., was brought to me by her physician, Dr. J. H. Bishop. I found her fairly well developed for her age, and well nourished. She gave the following history: She had always been well until within three months. Three months ago she suffered for about a week with cramp-like pains in the pelvis; at the end of four weeks she

again had the same symptoms, but in a somewhat exaggerated degree; again, at the end of four weeks she was taken with similar pains, which lasted, however, for three weeks. At the same time she observed that her abdomen was increasing in size. The physician who was in attendance looked upon the case as one of approaching puberty, and assured the family that in a little while menstruation would appear and all would be well. But as she was quite sick the family became dissatisfied and called in Dr. Bishop. He examined her abdomen, found a large mass to be present, suspected an ovarian tumor, and brought her to see me. On palpating the abdomen, three well-marked masses could be made out. The largest one was central and about the size of a four-months' pregnancy. The lateral masses were similar, but distinctly palpable. Upon examining the vulvar region it was found that the hymen was imperforate—a somewhat thick membrane blocking up absolutely the vaginal orifice. This membrane was quite congested, and what appeared to be dark fluid could be seen through it. The examination per rectum showed the presence of a cystic mass at the proper site of the vagina. A diagnosis of imperforate hymen with hemato colpos metra and salpinx was made. The patient was admitted to the Kensington Hospital for Women, and on November 27, 1893, the hymen was excised and the contents of the vagina permitted to flow out. The uterus was so fixed that it was difficult to find the cervix, and owing to the distention of the tubes it was not considered wise to use much force in searching for the os. After a time, however, this was found, and steadied by catching the cervix with the bullet forceps, while a two-way catheter was introduced and the uterus was irrigated. It is scarcely necessary to say that the operation was performed under rigid asepsis. An antiseptic occlusion pad was placed over the vulva, and the girl put to bed, with the expectation that the blood which was contained in the tubes would drain away through the uterus and vagina. A suppository of iodoform was kept in the vagina, which was douched twice daily with a weak bichloride solution. The patient did quite well until the sixth day, when she developed septic symptoms. The temperature ran up to 103.2° F. and the pulse to 120. At the same time she developed a cutaneous eruption so closely resembling that of measles, that this disease was suspected by some of the house-staff, more especially as the conjunctivæ were injected and a mild coryza was present. This rash disappeared within twenty-four hours. It probably was a manifestation of sepsis, but as the patient was taking quinine, and also as iodoform was being used per vaginam, it is barely possible that it was a drug eruption. Although the temperature and pulse continued elevated, and there was some tympany, the patient expressed herself as feeling pretty well, and after a few days the symptoms entirely subsided and she made an uninterrupted convalescence. She continued to have a bloody discharge for four weeks, which gradually became less until it ceased. She was discharged on December 23d, with instruction to report within two months.

A careful examination per vaginam on the day before her discharge disclosed the following conditions: The hymen absent, the vagina much thickened, and its muscular wall evidently much hypertrophied; the uterus enlarged and drawn to the left, and its mobility much below the normal. The Fallopian tubes, as such, could not be outlined; the large lateral masses which were present before the operation had disappeared.

The prognosis in this case, of course, is somewhat doubtful. The tubes may be so much damaged that they will never become normal; but, on the other hand, such adhesions as are present may be absorbed, leaving the tubes in such a condition as to make pregnancy possible.

The question of when to examine young unmarried women who are suffering from symptoms referable to the sexual organs, and when to treat such women by general measures, is one of those questions constantly being brought to the attention of the busy practitioner. In my judgment, there is no question which requires more careful study on the part of the practitioner, if, on the one hand, he would avoid an unnecessary shock to the maidenly modesty of his patient, and, on the other hand, if he would avoid the even greater evil of permitting serious organic disease to pursue its course to the great detriment of his patient, and possibly with the result of costing her her life. All judicious practitioners of experience will agree that it is unwise to make a pelvic examination in young unmarried women unless organic disease is present. It is very easy to lay down this broad rule for guidance, but when it is recalled that the only way to determine absolutely whether or not organic disease is present, is by means of a local examination, it is at once apparent that the whole question depends upon the good judgment and diagnostic instinct of the practitioner. My own rule is that, if the symptoms complained of are apparently of a trivial character, to study carefully the condition of the patient's general health, and to address my efforts toward the cure of whatever conditions may be present; those most frequently met with being anæmia, indigestion, constipation, neurasthenia, and emotional excitability. In this class of cases, if the patient does not improve and become well under judicious management, it then becomes necessary to make a local pelvic examination.

On the other hand, when the symptoms complained of are such as to point to marked local organic disease, the question as to whether the patient be married or single is of minor importance, as an unmarried woman has the same right to receive benefit from the resources of our art as has her married sister.

The question of how to make a physical examination in the unmarried, is also one demanding attention. In certain cases, I believe it to be wise to make the examination after the patient has been anæsthetized. This applies more especially to those women who express a great repugnance to the idea of submitting to a local examination, and especially to those who are of a highly neurotic temperament, including those who are hysterical. In such women it is very difficult to arrive at a satisfactory diagnosis as to the physical conditions present in the pelvis, without the use of anæsthesia. Many of them refuse to be passive, and either violently resist the examination, or, at least, are so nervous and agitated that they keep the abdominal muscles tense, so that the result of an examination, in many such cases, is simply that the patient is confirmed in her repugnance to the idea of submitting to local measures, and the physician is as much in ignorance as he was before he attempted the examination. Girls who are more phlegmatic and likewise more philosophical, will more generally submit patiently to what is necessary, so that a satisfactory examination is possible.

Anæsthesia as an aid to diagnosis in the diseases of women has here one of its most useful applications, and it goes without saying, that if what I have said be true of those who are specially skilled in genecology, it applies with greater force to the general practitioner, whose opportunities for acquiring special knowledge in diagnosis of the diseases of women is necessarily limited. In many cases examination per rectum will yield all necessary information, so that a vaginal exploration can be avoided.

The Therapeutic Value of Carica Papaya in Cancer.—Dr. Hirschfeld, of Brisbane, has been experimenting as to the value of papain, the digestive ferment contained in the juice of the unripe pawpaw apple, or carica papaya. He finds that it has no effect in checking the growth of cancer, but it has marked analgesic and antiseptic properties, and he explains the latter effect by its digestive action on the bacteria and on sloughing tissue, while it cannot affect living tissue in which blood is circulating.

The Kreutzer Sonata.—A young woman in St. Petersburg was driven to suicide by reading Tolstoï's Kreutzer Sonata.

Clinical Department.

A CASE OF ECTOPIC GESTATION—RUPTURE AT ABOUT ONE MONTH—IMMEDIATE LAPAROTOMY—RECOVERY.[1]

By W. M. SEWARD, M.D.,

NEW YORK.

Mrs. A——, from the country in Pennsylvania, married in 1891. On January, 1892, was delivered of a 3½-pound baby, which she had been nursing until the operation. On August 1, 1893, the patient was not feeling well, and on the 7th went to the country. A day or two later she had an attack of nausea and vomiting, lasting about seven or eight days, which she felt sure was due to some indiscretion of diet. On September 13th she menstruated, this being the first since the child was born. On September 28th she began to flow, the quantity equalling normal menstruation and lasting three days. After this there was a sanguineous discharge, which at times was replaced by a purulent one. Occasionally there would be no discharge for a day; after such times she would have slight cramps. The patient began to feel a pain in the right side about October 1st. The pain was almost constantly present, and gradually increased in intensity until Thursday, October 19th. On this day, at 11 P.M., while sewing, she felt severe cramps in her right side which necessitated her going to bed. I was sent for and found the patient suffering great pain; face not expressing any shock or loss of blood. Temperature normal; pulse about 100° F. The abdomen not distended. On vaginal examination I found os uteri soft, and slightly patulous, admitting the tip end of finger. The uterus was somewhat enlarged, and flabby. Palpation on left side revealed nothing abnormal, while on the right side the tenderness was so extreme that nothing more than slight thickening of the tissues could be made out. I ordered one-eighth of a grain of morphia, and an ice-bag to quiet the pain. On the next day the temperature was normal, and patient felt easier, and in evening at 11 was fairly comfortable. On following day, being thirty-six hours after my first visit, the patient felt much better, and wished to get up, but was advised to remain in bed. At 12 P.M. on Saturday night the patient again felt cramps, and more severely, too, than before. After the lapse of a few minutes she felt faint and vomited. I was at once sent for and found on my arrival the following symptoms: Marked pallor; skin bathed with cold perspiration; pulse 120, soft, and very feeble; patient suffering from air-hunger; the abdomen slightly distended, especially on the right side. Percussion revealed no special dulness. Vaginal examination gave same results as were obtained two days previously, except that there was a sensation imparted to the finger as if a semi-solid mass occupied Douglas's cul-de-sac.

An operation was at once advised and acceded to. I called in Drs. George W. Jarman and William J. Pulley, both of whom agreed with me that the only chance of saving the life lay in an operation. After very hasty preparation, and an attempt to render our surroundings as nearly aseptic as possible, which under the circumstances was no easy matter, the operation was performed as follows: Patient being etherized, abdomen was thoroughly scrubbed, and the field of operation surrounded with wet bichloride towels The usual incision, four inches long, extending through all the layers of the abdominal wall down to the peritoneum was made. The peritoneum being exposed, it presented a bluish-black appearance. By raising this up it was at once seen that this unusual color was due to fluid blood beneath the peritoneal layer. The peritoneum was opened, and blood, bright red in color, poured out over the abdominal walls. Underlying this free blood the interstices between the coils of intestines were filled with clots apparently of recent formation. The blood-clots being hastily removed with the hand the tube was sought, and in searching for it the index finger passed through a small opening, which was afterward found to be a ragged-edged opening into the tube itself. The tube was brought into view through the abdominal opening and free hemorrhage was still in progress from the edge of the opening in the tube. A clamp was at once made to grasp the broad ligament and tube between this opening and the uterine body. The hemorrhage being controlled, the tube, with its corresponding ovary, was secured by means of the usual interlocking ligature. The material used for this ligature was strong, softly twisted silk. The ligated mass was now removed. The patient at this time showed such feeble heart action that the pulse was with difficulty obtained at the wrist. Frequent hypodermic injections of brandy were administered. Realizing the importance of rapidly completing the operation, two quarts only of previously boiled water at a temperature of 116° F., were poured into the peritoneal cavity and hastily slushed out. Many clots escaped with this rapid washing. The cavity was not sponged dry, and a number of small clots were not removed, inasmuch as haste seemed to be a large factor in the safety to the patient; in addition to this, we felt confident that nature would be able to take care of and absorb the blood-clots and water which were left in the peritoneal cavity. The abdominal wall was closed with silkworm-gut ligatures passing through all the layers. An occlusive dressing of sterilized gauze and cotton was hastily adjusted, and held in place by an ordinary binder. The patient was put to bed in poor condition. No apparatus being at hand for the purpose of transfusion, an attempt was made to fill the depleted arteries and stimulate the enfeebled heart, by means of a rectal injection, consisting of six ounces of saline solution and one ounce of brandy; a hypodermic was also given, consisting of one eight grain of sulphate of morphia and one-sixth grain of sulphate of strychnia. The foot of the bed was elevated and hot-water bottles placed around the patient. In a short while the pulse became more perceptible at the wrist and less frequent. In the hurry, and owing to the unseasonable hour, about 3 A.M., the quantity of blood was not measured, the sole object being to save the patient's life; judging by the eye, however, it seemed to be about one quart. Drs. Jarman and Pulley concurring in this opinion.

The operation was completed in about twenty-five minutes. At 12 A.M. patient was in good condition; pulse, 130; temperature normal. At 5 P.M., pulse, 122; temperature normal. On the second day, 9 A.M., pulse, 132; temperature, 102½°; 6 P.M., pulse, 140; temperature, 102°. Third day, 9 A.M., temperature 103½°; pulse, 144. Dressing was removed and wound found to be in good condition. A fresh dressing was applied. 8 P.M., pulse, 130; temperature, 101½°. Fourth day, 9 A.M., temperature, 101°; pulse, 120. 9 P.M., temperature, 100° F.; pulse, 118.

The patient up to this time had been slightly delirious; probably from cerebral anæmia. On the fifth day the abnormal mental symptoms disappeared; A.M., temperature, 99°; pulse, 112. P.M., temperature, 98½°; pulse, 100. During the existence of the delirium, patient voided her urine involuntarily; but after consciousness returned it was necessary to resort to catherization for two days. Sixth day, pulse, 96, and temperature normal On this day an ordinary stimulating enema was given, which was followed by a normal movement and an escape of gas. After this time urine was passed normally. Seventh day, everything normal. Eighth day, dressing was removed and union of wound was found to be perfect. A fresh dressing was applied. On the tenth day the stitches were removed. The convalescence from this time was uneventful. At the end of two weeks from the time of operation the patient was allowed to sit up, and at the end of three weeks to walk about the room. She resumed her duties as housekeeper six weeks after the operation, and normal menstruation occurred December 4th to 7th.

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, March 10, 1894.

THE NATIONAL QUARANTINE BILL.

THE bill to establish a Bureau of Public Health prepared by the National Quarantine Committee of the New York Academy of Medicine, has been fully revised and amended, and is now in proper shape for passage before both legislative branches at Washington. The present draft is the result of a wide-spread conference with medical societies and sanitary authorities over the country, and is calculated in the most general and effective way to reconcile previous differences, not only as to matters of detail, but as to other more essential features that appeared to deserve more candid and deliberate consideration.

As at present modified the bill establishes the Bureau of Public Health, not in the Treasury Department, as was at first proposed, but in the Department of the Interior, where it more properly belongs. At the same time the practical administration of maritime quarantine remains in the Treasury Department, in which it can command the experience and resources of the Marine Hospital Service.

Its original purposes and intention are fully set forth in the definition of the duties of the Bureau, and comprise the collection and diffusion of information upon all matters affecting the public health, including statistics of sickness and mortality in different States; the investigation by experimental and other methods of the causes and means of prevention of disease; the collection of information with regard to the prevalence of contagious and epidemic diseases in this and other countries; the publication of information thus obtained in a weekly bulletin; the preparation of rules and regulations for securing the best sanitary condition of vessels from foreign ports, and for the prevention of the introduction of infectious diseases into the United States, and their spread from one State into another, which rules when approved by the President shall have the force of law; the ascertaining by suitable inspection that these rules are properly enforced; the advising and informing the several departments of the government, and executives and health authorities of the several States on such questions as may be submitted by them to it, or whenever in the opinion of the Bureau such advice and information may tend to the preservation and improvement of the public health; and in general, to be the agent of the General Government in taking such action as will most effectually protect and promote the health of the people of the United States.

In order that these comprehensive and radical measures may be properly and efficiently carried out, it is further provided that the executive functions shall comprise an Advisory Council, consisting of one member, a physician, from each State, appointed by its governor, and a Commissioner of Public Health, who shall be an expert sanitarian, appointed by the President, who shall receive a salary of $6,000 per annum, and shall be the responsible head and executive of the Bureau.

It will thus be seen that while the responsibility for the administration of the affairs of the Bureau is placed as before in the hands of a Commissioner of Public Health, the Advisory Council is now composed of one representative from each State. In this way a more full and just representation of the sanitary knowledge and experience of all parts of the nation is secured than by the earlier plan, which gave a representation in the Advisory Council, not of each of the States, but of large and perhaps unwieldy groups of States forming the so-called sanitary districts. The Advisory Council is to meet in Washington at least once a year and its members receive no compensation other than their necessary expenses.

This is a rational and feasible measure, and well calculated to harmonize previous differences of opinion on executive points; at the same time the representation in the Board is thoroughly national and reasonably distributive.

In the matter of establishment of national quarantine here and abroad, no essential changes are proposed, while ample provision is made for helpful assistance to local health boards. In fact, nothing seems left to be desired in the way of making this proposed law the most perfect, from a national point of view, that has yet been offered for the approval of the legislators. It is a model of its kind as it stands, and we bespeak for it the heartiest approval of the medical profession, the unqualified endorsement of the sanitary authorities, and the substantial and intelligent support of the public.

The country sadly needs just such a central educating, stimulating, and harmonizing influence as this bill creates. It has needed it for a long time. And it is difficult to believe that a legislative proposal so universally beneficent in its nature and so wholly free from partisan ideas of any kind will meet with legitimate opposition, if it can once command a hearing amid the hubbub of many matters of far less intrinsic importance to the people of the United States.

The time for definite action has now arrived. The season for threatened epidemics is approaching, and after all the pains taken and labor expended upon the bill by the Committee of the Academy, and after the conclusive arguments that have been presented for the necessity of the measure, it would be a shame and a disgrace to a great country not to be suitably prepared for every possible emergency. We congratulate the Committee on its eminently successful work, and bespeak for it a becomingly high appreciation of its arduous and unselfish labors in the cause of public health, and the consequent interests of public safety.

The Physicians of the United States now number 118,453; New York leads, with 11,171; Pennsylvania has 9,310, and Illinois ranks third with 8,002.

A GRAND JURY AND A HOSPITAL.

THE question of the management of hospitals has received some interesting contributions at the hands of a Grand Jury. This jury paid a visit to the hospitals, and appear to have familiarized themselves with the details of hospital accommodation and construction in about one hundred and eighty minutes.

The Medical Board, after a long investigation, with the amplest opportunities for gaining the facts, reported that the diet was inadequate and poor in quality. In July, 1893, there were 540 cases of diarrhœa in a population of 1,800. Such figures mean bad food as plainly as two and two make four.

As to air space, the Workhouse hospital has 13,000 cubic feet of air and 23 beds, thus allowing 500 cubic feet per person. Now, all sanitary and hospital authorities agree that a hospital ward should allow about 1,300 cubic feet of air per bed, and a supply of 3,600 cubic feet of fresh air per hour.

As to nursing, there were, in a ward of thirty sick men, one trained nurse by day and one untrained nurse by night. In a properly equipped hospital there are at least four nurses for every ward of twenty beds. The Grand Jury had perhaps never seen a properly equipped hospital.

"By their fruits ye shall know them." The mortality-rate for the year 1893, at the Almshouse, was 646 deaths and 872 cases discharged alive, giving a ratio of forty-two per cent.

We cannot but think that the Grand Jury which found so little wrong with the management of the hospitals under investigation is one easily pleased, or easily misled.

POVERTY AND DISEASE AS STUDIES IN SOCIOLOGY.

THE study of sociology from the standpoints of heredity and disease, brings to the thoughtful student many significant facts for consideration. The causes of the survival of the un-fittest are thus plainly presented, and are suggestively fruitful of research. The physician, in his constant and intimate relations with the poor and sick, is naturally entitled to an opinion. Especially is this the case when he views his subject on the basis of broad principles, and on wide areas of comparison. We are consequently pleased to notice in these connections some interesting data and reasonable conclusions therefrom, which are offered by Dr. Henry D. Chapin, of this city, in a recent article in the *Forum*.

Of the two leading factors, heredity and environment, as explaining poverty and disease, Dr. Chapin is led to believe that the latter is the more important. So far as his observations have gone, such appears to be the case. Whether the conclusions can be assumed to be absolute or not, from necessarily limited statistical facts, they are at least somewhat novel to such as give their attention to the solution of questions of sociology.

Six hundred cases of children with various diseases and environment form the basis of the study. Of these a trifle over five hundred were in good condition at the time of birth, while half of that number were deprived of maternal nourishment before the proper time, and one-fifth had never received it at all, as the mothers were compelled to go out to work.

The inquiries into the condition of parents showed that the combined earning capacities of the families were, in 150 cases, between $5 and $10 per week, and in 117 cases, $5 or less per week. In many of the last class of cases a father and mother, with several children, were obliged to subsist on a weekly income of from $3 to $4. Of his 600 hospital children, only 100 died, leaving the other 500 to attempt the struggle for life for which they are in every way insufficiently prepared, cramped from the beginning of life by cold and hunger, and by their weakened physical condition inviting an invasion of those degenerative diseases which always, to a greater or lesser degree, handicap them in the subsequent life struggle.

The common history of poverty appeared to be that the man, unable to get steady work, either through fault of misfortune, after spending much of his time at a saloon, would suddenly leave for parts unknown. In such cases drinking habits were both a cause and an effect or misfortune. There is no doubt in the mind of the author that the saloon is the greatest curse to these people, in absorbing their scanty resources. Every saloon in a poor and densely populated neighborhood, meant so many neglected women, and pinched, ill-clad, suffering children. Among 200 cases in which direct inquiry was made, 14 were drunkards, 140 claimed to drink in moderation, 31 were abstainers, and the habits of fifteen were unknown. In a few cases husbands had been deserted by their wives. In many the poverty was extreme, as might be expected from the disinclination of even the poorest classes to leave an infant or very young child in a hospital.

In conclusion Dr. Chapin significantly remarks: "After much observation in hospital and dispensary, I am convinced that there is no specific for the poverty and ignorance that are so wide-spread. The cause, as well as the cure, must be individual and social. It is along these two lines that amelioration should take place. Whether there will actually be improvements depends largely upon the more intelligent and better favored classes. The first duty is toward the individual. He must be educated and strengthened, physically, mentally, and morally, so as to make the best of the resources at hand and thus have a better fighting chance. But individual improvement requires individual and prolonged work on the part of those who are better equipped. Comparatively few are willing to engage in such work. But the fault is not always or entirely with the individual. Our civilization has become too selfishly individualistic. The law of competition is pushed to its extremest limits. Here we have 117 families, in a small area of a city, with an earning capacity of from $2 to $5 per week, and ten per cent. of the entire inhabitants dying in the city have not accumulated enough in a lifetime to procure burial for themselves."

And yet the charitably disposed persist in working at the wrong end of the problem, by encouraging pauperism in the senseless wide-spread and indiscriminate distribution of so-called charity. Let us by all means, then, study the causes of poverty and disease that we may be able the better to apply the remedy.

Small-pox is so prevalent in Chicago that measures are advocated for a quarantine of fifteen days for suspected cases.

TO GIVE RANK TO THE ACTING ASSISTANT SURGEON.

On former occasions we have felt it our duty, in speaking for the rights of the late acting assistant surgeons of the army, to urge the removal of the disabilities under which they have so long labored. At last a bill has been introduced into Congress having such an end in view, and in which the following provisions are set forth:

"That private physicians who were employed as medical officers in the armies of the United States for a period of not less than three months, in accordance with paragraph 1268 of the Revised Regulations, United States Army, 1861, and paragraphs 1304 and 71, Appendix B, Revised Regulations, 1863, and who were known officially as acting assistant surgeons of the United States Army, and whose services were honorably terminated, shall be commissioned by the President of the United States as acting assistant surgeons of the United States Army; and the date of employment as acting assistant surgeons to be the date of commission and muster into service, and the date of the honorable termination of service as acting assistant surgeons to be the date of discharge or muster out of service: *Provided*, That no pay or allowance shall be made to any such acting assistant surgeon by virtue of this act; and this act shall not affect the rank, pay, or emoluments of commissioned medical officers of the United States Army."

The objects are legitimate and reasonable, and we trust that in justice to the good work done by this corps during the late war, the bill will receive a proper recognition.

COMPULSORY NOTIFICATION OF TUBERCULOSIS.

The Michigan State Board of Health has officially declared tuberculosis to be one of the "diseases dangerous to public health," and requires notification and registration of cases. The Board does not propose isolation, but apparently intends simply to send circulars of warning and information to every family or person found tuberculous.

The Pennsylvania State Board of Health is considering the plan of issuing a similar order, and considerable opposition seems to have been awakened among the Philadelphia physicians. The objection is that notification and registration of infected persons would create a panic, and do little good so long as quarantine and disinfection cannot be carried out. It is thought that every physician now-a-days who can recognize tuberculosis, can also prescribe efficient means for preventing its dissemination.

Dr. Da Costa says: "Why fix the brand of leper on a poor unfortunate because he has consumption, when the medical officer can do all that is necessary? He can instruct how to ventilate and keep the house pure, and how to disinfect the sputa. What more could a Board of Health do? What can it do, except in instances of death in which proper disinfection may not be carried out? When death has occurred, and when disinfection is not likely to be practised, it would be proper for the Board of Health to interfere. Under other circumstances, why should we place a stigma on the consumptive, why have him pursued from house to house, why have him a marked man, why have the house a marked one? Why give it a bad name and injure the landlord because there has been a death from consumption in it?"

Dr. J. S. Billings says, "If it were possible, by a systematic notification, for the Board of Health to locate a considerable number of these infected houses, what steps would it take to purify them? How would it deal with those of the poorer classes who are affected with this disease, and with their furniture, bedding, and rooms? Until these questions are answered, I do not find it possible to form a definite opinion as to whether it is worth while to put in force a compulsory system of notification.

Dr. Solis-Cohen is still more positively against the proposed regulation. Undoubtedly, compulsory notification would entail much distress of mind, yet it would be a most powerful means of stimulating the poor to cleanliness, and of educating them in the methods of preventing disease.

News of the Week.

Dr. F. Montizambert, of Toronto, Canada, has been appointed by the Dominion Government, General Superintendent of the Canadian Quarantine Service. No better choice could have been made for this responsible office.

Death of Dr. H. C. Cooper.—Henry Cooper Cooper, M.D., clerk of the faculty at the Medical College of the University of the City of New York, 410 East Twenty-sixth Street, died suddenly of heart disease, March 4th, aged sixty years. Dr. Cooper had held the post of clerk nearly eighteen years. He obtained his degree at the college, graduating in the class of '81.

Improper Treatment of Insane Patients.—Complaint has been made by the superintendent of the Kankakee Asylum, that insane patients are badly treated at the Chicago Detention Hospital. The report says: Female patients were compelled to submit to being disrobed by men. In other cases the straps used in restraining the patients were so carelessly put on, and such disregard of cleanliness was displayed, that in two cases the evidence indicates that death resulted from blood-poisoning.

Dovetailing Deficiencies.—At a recent meeting of the Hospital Graduates Club one of the members exhibited a man who had suffered total excision of the tongue and floor of the mouth for cancers, while another member showed a man whose larynx had been wholly removed for the same disease. Both of the patients could speak very intelligibly. While waiting in an adjoining room, before being shown, they scraped acquaintance, and when summoned were found engaged in animated conversation!

Death of Dr. F. G. Payn.—Dr. Frederick G. Payn died March 5th at his home in Bergen Point, from the effects of an operation for appendicitis performed for his relief several days before. Dr. Payn, who was in his seventieth year, was a native of England. About forty years ago he began to practise medicine in Bayonne. He was the first president of the Bayonne board of health. Upon the formation of the Bayonne hospital association, several years ago, he was made president of the board of physicians and surgeons. He was also for years a member of the medical staff of St. Francis Hospital, in Jersey City.

Quintuplets.—The wife of Mr. Rosenberger, of Kittanning, Pa., gave birth to five children on Wednesday of last week. The birthplace of the children, although curiously spelled, has a significant association with the event.

Death of Dr. Messemer.—Dr. M. J. B. Messemer, formerly coroner of this city, died of diabetes in Mentone, France, February 21st.

Hiccoughed his Teeth Loose.—We are nowadays hearing dreadful tales concerning the ravages of a new epidemic of hiccough. This time a Western paper reports the case of a Portland man who never took a drink of liquor in his life, but who hiccoughed for eighty hours, never lost a stroke, and loosened all his teeth; thus proving the energy of the terrible reflexes of his lower jaw, and the sustaining power of his restless diaphragm.

Twenty-eight Years Its Secretary.—General Emmons Clark celebrated, March 5th, the twenty-eighth anniversary of his appointment as Secretary of the Board of Health of this city, which office he has held continuously since the formation of the department. General Clark is the only one connected with the Board who was one of its original officers. We wish him many happy returns.

The Final Results of the Hyderabad Commission on Chloroform Anæsthesia.—The Secretary of his Highness the Nizam of Hyderabad has addressed a letter to W. H. Gaskell, M.D., F.R.S., and L. E. Shore, M.D., Cambridge University, and H. A. Hare, M.D., Professor of Therapeutics, and E. Q. Thornton, M.D., Demonstrator of Therapeutics, Jefferson Medical College, Philadelphia. The letter is dated Hyderabad, January, 1894. The letter goes over the history of the Hyderabad Commission's work on chloroform, and says: 5. The researches of the Hyderabad Commission confirmed Syme's principles. The Commission proved that: *a*. Chloroform and shock are incompatibles. It was found to be impossible to stop the action of the heart by any form of shock under chloroform. *b*. In death by chloroform the respiration always stops before the heart, which beats effectively for a considerable time after the breathing has ceased. *c*. The lowering of the blood-pressure which is produced by the narcotic action of chloroform is harmless, and cannot be due to weakening of the heart. *d*. Chloroform anæsthesia is free from risk. As long as the breathing is natural and regular, and the inhalation is not continued after anæsthesia is complete, over-dosing with chloroform is impossible. *e*. The pulse is never appreciably affected by chloroform, except through interference with the breathing or by over-dosing. 6. The experiments of the Hyderabad Commission did not satisfy the profession. The Commission's evidence of the absence of direct heart failure under chloroform was said to be wholly negative, and further experiments were rightly demanded in order to show the cause or causes of the fall of the blood pressure. 7. These experiments were undertaken on behalf of his Highness the Nizam's Government by two of the greatest living authorities on physiology and physiological therapeutics, Dr. Gaskell in England and Dr. H. A. Hare in America. Dr. Gaskell was assisted by Dr. Shore, and Dr. Hare by Dr. E. Q. Thornton. 8. The experiments of Drs. Hare and Thornton substantiated those of the Hyderabad Commission. They found that it is not possible "in lower animals (the dog) to cause cardiac death by the freest use of chloroform by inhalation, without first causing respiratory arrest. And their report concluded in the following terms: "We agree so heartily with Lawrie's conclusions" (which are those of the Hyderabad Commission) "that we print them below." 9. The value of Dr. Hare's report will be more thoroughly appreciated when it is remembered that it is directly opposed to the conclusions published, only four years ago, by himself and Professor H. C. Wood, of Philadelphia; and that it is also altogether opposed to the statement made by Professor Wood, at the Berlin International Medical Congress in August, 1890: "We definitely proved that in the dog chloroform has a distinct direct paralyzing influence on both respiration and circulation, and that in some cases the heart is arrested before respiration." 10. The fallacies of Professor Wood's experimental and clinical data were exposed in the *Lancet* and in the Hyderabad Commission's Report on Chloroform (page 274), and it is satisfactory to note that the report of Drs. Hare and Thornton indicates that they have convinced themselves that the opinions of Professor Wood were founded on error.

Cross-circulation experiments established the following facts in addition to those already made good by the Hyderabad Commission: *a*. Chloroform has no direct action on the heart or circulation. The heart can only be affected under chloroform by interference with the breathing or by overdosing, which is practically the same thing. Accordingly, it must be futile and dangerous to take the pulse as a guide to its effect. *b*. The lowering of the blood-pressure, which is caused by an effective dose of chloroform, is due entirely to its direct narcotic action on the brain, and is a safeguard to the heart, by dilating the smaller arteries and facilitating the flow of blood from the arterial to the venous system, thus diminishing its work and relieving it of strain. Syme's principles of chloroform administration are, therefore, physiologically correct, and there is no longer the shadow of an excuse for the impotent and dangerous "finger on the pulse while chloroform is given." The Nizam has directed that a piece of silver plate be sent to each of the gentlemen to whom the letter was addressed.

The College of Physicians and Surgeons, of Philadelphia, has apparently concluded to enter upon a new stage of development, by authorizing the organization of Sections among Fellows of the College, for the special consideration of different branches of medical practice. Last year the Ophthalmic Section was instituted and held regular meetings each month, at which much interest was shown and many good papers were read. The Orthopedic Section was formed next, and recently a Laryngological Section was organized which held its first meeting in January. On February 1st a Section on General Surgery was formed, and others are expected to follow shortly. The College is the owner of a fine building and a valuable library and museum, and is well equipped for entering upon an era of greater activity than it has ever hitherto witnessed in its long and honorable career. —*Journal of the American Medical Association.*

Consumption Contagious.—At the suggestion of Health Commissioner Emery, of Brooklyn, the Kings County Medical Society recently considered the proposi-

tion to place consumption on the list of contagious diseases, and subject to the usual restrictions. The report of the Society makes these recommendations: 1. That the secular press, circulars, etc., be utilized to educate the public, that pulmonary tuberculosis is an infectious disease, and that it is acquired by the direct transmission of tubercle bacilli from the phthisical to those who are in health, by means of the dried and pulverized sputum floating as dust in the air, and through infected meat and milk, and that it can be largely prevented by simple and easily applied measures of cleanliness and disinfection, and by sanitary control of the meat and milk supply. 2. That all public institutions, such as asylums, homes, hospitals, dispensaries, etc., be required to transmit to the Board of Health the names and addresses of all persons suffering from pulmonary tuberculosis within seven days after the time that a positive diagnosis can be made. 3. That the Health Department establish a hospital, to be known as the consumptive hospital, to be used for the exclusive care and special treatment of this disease, and that, so far as practicable, all inmates of other institutions suffering from pulmonary tuberculosis be transferred to this hospital. 4. That the Health Department undertake the bacteriological examination of the sputum for diagnosis in every case of pulmonary disease, of whatever character, in the hospitals or private dwellings or tenement-houses, when the physician in attendance desires that this be done; this procedure to be carried out with a view of obtaining definite knowledge upon which the proper sanitary surveillance of those suffering from tuberculosis can be based. 5. That whenever the Health Department has become aware of the existence of a house or premises where tuberculosis exists or recently existed (as in case of death or removal), it shall take such specific measures as are required in each case. 6. That the Health Department secure the passage of an ordinance by the Common Council of this city requiring corporations controlling public conveyance to frequently disinfect such parts of their property as are contaminated with expectorations. 7. That a special bureau be established, to be known as the bureau of pathology, bacteriology, and disinfection, for the proper performance of the work as detailed above, and to which shall be referred the investigation of all cases of infectious and contagious diseases that may require the attention of the Health Department. 8. That the Health Department cause a frequent examination of the milch-cows from which is derived the city's milk-supply, and the examination of the animals killed for food at the slaughter-houses of the city, and for that purpose only qualified veterinarians be employed. 9. That the Commissioners determine and limit the minimum of space to be allowed to cows furnishing milk to be sold in this city.

The Prospective Success of the International Medical Congress.—Already the number of "congressisti" announced as expected by the Secretary General is fully six thousand. It is contemplated to hold evening sittings, and for this purpose forty lamps furnished with electric light are in preparation. In the *locali* of the upper floor of the Palazzo the "Esposizione Internazionale d' Igiene e Prodotti Medicali" will be accommodated, space having been found for the specimens contributed by the five hundred exhibitors. Nothing can exceed the almost febrile activity with which these preparatory works are being prosecuted, while the new *locale* has certainly this advantage over the Policlinico that it is much more central—much nearer the principal hotels—and within easy hail of cab, tram-car, and omnibus. The proximity of the "International Exhibition of Hygiene and Medical Products" to the seat of the Congress is another convenience secured by the arrangement finally come to for the economy of time and the cost of conveyance.

Ambrose Paré.—It is not generally known that the origin of the great reputation of the father of French surgery, Ambrose Paré, was due to an incident that occurred at the siege of Boulogne sur-Mer. The Duc de Guise had been carried to his tent with a fearful wound, produced by the point of a lance. The lance had entered the cheek of the prince under the right eye, and passed out in the neck under the ear. The weapon broke in the wound. His surgeon, Ambrose Paré, arrived, and said to his assistants: "Gentlemen, the prince is not dead, but he will be soon in the other world unless, regardless of any respect for his person, I pull out at once this shaft from his head." Planting his foot on the face of the prince (!) he seized the piece of iron with his fingers, and after a considerable see-saw movement he succeeded in drawing it out. The prince recovered, and bore ever afterward the nickname of *Balafré*.

Medical Fortunes.—In Dr. Chesterfield's "Letters to His Son on Medicine as a Career," recently published by Sir William Dalby, it is stated "that at the same time in London there are not more than four or five general physicians, and perhaps half-a-dozen surgeons who make more than five or six thousand a year. The *British Medical Journal*, commenting on this, collects a number of items regarding the fortunes acquired by English physicians and surgeons. Dr. Mead left a library and other property valued at £50,000, but £20,000 in money. The personality of Sir Benjamin Brodie was sworn under £18,000, that of Sir William Lawrence under £40,000, and that of Dr. Murchison under £50,000, chiefly inherited. The will of Sir William Gull, which was sworn under £344,000, is generally quoted as the largest amount left by a member of the medical profession. This, however, was exceeded by Dr. Blundell, who died in 1877, and left a fortune of £350,000. Among other wills of six figures may be mentioned Sir Erasmus Wilson, £264,000; Sir Andrew Clark, £204,000; Sir Oscar Clayton, £146,000; Sir George Burrows, £104,628; Sir William Bowman, £103,948, and Sir C. Locock, £100,000. Sir Astley Cooper must have made a large sum by his practice; his income is said to have been £15,000 for many years, and in one year to have reached £21,000; his will was sworn under £80,000. Of the fortunes made by members of the medical profession, very little has been left to institutions connected with that body. A notable exception to this stands out in the munificent bequest of Sir Erasmus Wilson to the Royal College of Surgeons, by which that corporation received £200,000; in addition to this bequest, Sir Erasmus left £5,000 each to several institutions and charities connected with the medical profession.

A Bill has been introduced into the Ohio Legislature forbidding circumcision.

Reviews and Notices of Books.

THE DISEASES OF THE MALE ORGANS OF GENERATION. By W. H. A. JACOBSON, M.Ch. Oxon., F.R.C.S., Assistant Surgeon to Guy's Hospital. 8vo, pp. 758. Philadelphia: P. Blakiston, Son & Co. 1893.

THIS work refers to the surgery and pathology of the male genital organs, exclusively of syphilis and gonorrhœa. The author confines himself to the diseases of the testicle, scrotum, vesiculæ seminales, spermatic cord, and penis. In the treatment of each of the subjects he discusses their structure, anomalies, and pathological conditions, and the different recognized treatments therefor. The two latter divisions are particularly well considered, their discussion being strikingly elaborated by voluminous references to other authorities. While giving due credit to other observers the author is frank with his own methods, and gives the reader the results of his personal experience. Aside from the purely practical part of the work there is an almost exhaustive reference to rare pathological conditions of the different organs treated, and which is not to be found in any work of its kind. The illustrations, many of which are from the works of Curling and Osborn, are beautifully demonstrative, and serve to match the clear and terse style of the author.

No reference is made to disease of the prostate, for which omission the author apologizes on account of space. Still we hardly think this consideration should have been taken into account, in view of the uniform excellence of the work as it is, and the implied necessity of including every part pertaining to the general subject.

THERAPEUTICS OF CHOLERA. By P. C. MAJUMDÁR, M.D. Philadelphia: Boericke & Tafel. 1893.

THIS little work represents the "fruit of continual labors for fourteen years in the so-called home of cholera." The subject matter is confined to seventy-six pages abounding in orthodox homœopathic advice. The array of drugs to be employed for the multitudinous symptoms of cholera is truly bewildering to ordinary physicians; and yet the homœopath treats cholera with as much "success" as the regular doctor.

ESSENTIALS OF BACTERIOLOGY: Being a Concise and Systematic Introduction to the Study of Micro-organisms, for the Use of Students and Practitioners. By M. V. BALL, M.D., physician to the Eastern State Penitentiary at Philadelphia. Second edition, with eighty-one illustrations, some in colors, and five plates. Saunders's Question Compends. Philadelphia: W. B. Saunders. 1893.

THIS little work is precisely what it pretends to be, namely, an introduction to the study of modern bacteriology. The author has carefully compiled from recognized authorities those views which are generally received as having reached the maturity of facts. Mere opinions and theories are left out, and the student is not misled by being confronted with a mass of mere assumption. The work adequately fulfils the purposes for which it was written.

THE PRINCIPLES AND PRACTICE OF SURGERY. By JOHN ASHHURST, Jr., M.D., Barton Professor of Surgery and Clinical Surgery, University of Pennsylvania. Sixth edition. 8vo, pp. 1166. Philadelphia: Lea Brothers & Co. 1893.

THE present edition, which is the sixth, is enlarged by fifty pages and much new material has been introduced. The conciseness of the author has enabled him to crowd an immense amount of information into a comparatively small compass. While this necessarily interferes with detailed descriptions, more especially necessary for the beginner in surgery, increased opportunities are given for the reference to general principles which have been established in the author's mind after a long experience as a teacher and hospital surgeon. The work is profusely illustrated, contains one colored plate of streptococci, and some of the hackneyed historical cuts are replaced by new ones, mostly from the author's collection. The chapters on the eye, ear, and gynecology are excellent in their way, but are much too brief and unavoidably dogmatic to be of service to the student with one book on surgery. The part on surgical bacteriology, which is a new addition, is clearly and sufficiently presented, and is of proportionate value. In reference to some of the newer operations the author does not put himself in the advance with other writers; for instance, he does not approve of appendectomy, but only advocates operation for appendicitis when abscess has formed.

It is unnecessary to refer to the forcible style of the writer, which has been acquired by long experience as a contributor to surgical literature and a long service in practical teaching.

SYPHILIS: ITS TREATMENT BY INTRA-MUSCULAR INJECTIONS OF SOLUBLE MERCURIAL SALTS. By EDWARD COTTERELL, F.R.C.S., Eng., etc. Surgeon (Out-Patients) London Loch Hospital; Surgeon to the West End Hospital for Epilepsy and Diseases of the Nervous System; Surgeon to the Cancer Hospital, etc. London: John Bile & Sons. 1893.

THE author of this little brochure is a strong advocate of intra-muscular injections of sozoiodol of mercury in the treatment of syphilis, and he gives here his arguments in its favor and also his method of employing the salt. His plea is well and temperately expressed, and is likely to make converts.

SCIATIC NEURITIS: ITS PATHOLOGY AND TREATMENT. By ROBERT SIMPSON, L.R.C.P., L.R.C.S. Bristol: John Wright & Co. 1893.

THIS monograph is a plea for the more general adoption of massage as a therapeutic measure in cases of sciatica. The author has himself obtained such satisfactory results from this method that he naturally desires to see its employment become more frequent. He argues well and convincingly.

A Curious Phase of Professional Jealousy.—In this city it is not uncommon for two physicians to occupy the same house. In Western cities, a number of physicians sometimes occupy neighboring rooms in the same building. Contiguity is considered helpful rather than otherwise. But they do things differently in France. The Paris correspondent of *The Lancet* writes: "The tradition which sanctions the refusal of a French landlord to let rooms in his house to two persons pursuing identical or analogous callings, does not apparently extend to the medical profession. Those who, like myself, have acquired experience of apartment-hunting in Paris will know that, as a matter of fact, the presence of a *confrère* in any house constitutes almost invariably a bar to his own entrance therein; but that a landlord is within his right in 'taking in' two practitioners and even letting to them rooms on the same floor, is proved by a judgment recently delivered by the Fifth Chamber of the Civic Tribune of the Seine. Dr. S—— objected to the proximity of a new arrival, Dr. R——, and the intervention of the Syndicate of Doctors of the Department of the Seine, made at the request of Dr. S——, having failed to induce Dr. R—— to abandon his intention of taking the rooms, Dr. S—— sued his landlord for 10,000 francs damages, basing his action on the latter's verbal promise not to admit another practitioner into the same house. Seeing that the lease held by Dr. S—— contained no clause to that effect, the court non suited the complainant. *Apropos* of practitioners' residences, it may not be generally known that there exist in Paris no such 'doctors' streets' as, for example, Wimpole Street and Harley Street. Paris practitioners are not a gregarious class, and professional jealousy is, unfortunately, a not unknown quality."

Society Reports.

MEDICAL SOCIETY OF LONDON.

Suppurating Ovarian Cyst Communicating with the Rectum.—Mr. H. Cripps read a paper on four cases of suppurating ovarian cysts which had discharged into the rectum. In the first case the symptoms were acute pain in the left iliac region, which was soon followed by a swelling, and later by a copious discharge of pus per rectum. On examination the cervix was pushed to the left and a nodulated swelling could be felt. A small opening with ragged edges was found in the rectal wall. Drainage of the cyst through the vagina allowed the rectal fistula to heal. After a laparotomy and the the removal of two cysts the patient made a good recovery. The second patient had, two months previously, given birth to a child. Six weeks after this she felt something give way, and this was soon followed by a discharge of pus per rectum. Laparotomy showed a cyst apparently originating in the broad ligument and adherent to the bladder and rectum. Its removal was followed by a perfect recovery. The third case was one of tubal gestation communicating with the rectum in a woman of thirty. She had had three attacks of cramp-like pains, then the abdomen was opened and the sac and tube removed. The patient recovered. The fourth case of what was suspected to be old intra-peritoneal pelvic abscess died on the seventh day after the removal of a suppurating cyst in the broad ligament. These four cases were all that the writer had met in over one hundred cases of ovariotomy.

PATHOLOGICAL SOCIETY (LONDON).

Rupture of Sigmoid Flexure. — Mr. James Berry showed a sigmoid flexure which had become enormously distended, ulcerated, and perforated as the result of simple chronic constipation. There was no stricture or mechanical cause for the obstruction. The immediate attack of constipation which was followed by the rupture had been of ten days' duration. He regarded the dilatation of the intestine leading up to the rupture as purely passive.

Hermaphroditism.— Mr. E. Willett presented a specimen illustrating a well-marked example of hermaphroditism. The patient, a man forty-four years of age, married, and his wife had borne two children. In the pelvis between the two layers of the broad ligaments was an imperfect uterus and vagina. The scrotum contained two well-formed tunica vaginalis but no testes, as these were situated in the position normally occupied by the ovaries in the posterior layer of the broad ligament. From each testis a set of vasa efferentia led to form the globus major of the epididymis, and from the globus minor a convolute tube led to the side of the vagina. There was a solid Fallopian tube on each side going from the cornu of the uterus to the epididymis.

MEDICAL SOCIETY OF THE HOSPITALS (PARIS).

Variola and Vaccinia.—Dr. Juhel-Renoy said that variola and vaccinia had been considered clinical transformations of the same disease. In other words vaccinia had been considered to be a modified form of small pox. The Commission of Lyons presided over by Chanveau in 1835 had concluded the duality of these two affections. Meanwhile some experiments made in Germany since 1881, have tended to demonstrate the unity of the two affections. The writer, with the aid of his interne, Dr. Dupuy, made a series of experiments with a view of throwing some light on this question, and as the results of their experiments they are forced to the conviction of the duality of the two diseases.

Thyroid Feeding in Myxœdema.—Drs. Marie and Guerlain reported a case of myxœdema treated successfully by the administration of the sheep's thyroid and pointed out the accidents attending such treatment. The patient, a woman, had suffered with most pronounced symptoms of myxœdema for eight years. She was given what was supposed to be thyroids, for some time, without beneficial results, until a microscopical examination of the glands that were being used showed them to be the submaxillary. The real thyroid was then given, two glands at one dose. The next morning the temperature was 38° C. It continued to be elevated for two days, and later there was considerable perspiration, pricking sensations in the legs, and insomnia. A continuation of the thyroids aggravated these symptoms and the dose had to be lessened to one-half thyroid per diem. The amelioration of the myxœdematous condition was very prompt, and two months after the advent of the treatment the patient was entirely cured. The weight dropped from 102 kilos to 85 kilos. The mental symptoms kept pace in improvement with the physical. The readers of the paper emphasized the importance of this treatment and the necessity for care and prudence in its application.

BIOLOGICAL SOCIETY (PARIS).

Microbes in the Alimentary Tract.—Drs. Gilbert and Dominici read a paper on the number of microbes found normally in the digestive tract. They computed the number of microbes per milligramme in the fecal matter of two adult men. In one they found 67,000 microbes per milligramme, in the other 80,000. By a simple calculation it is seen that if the normal amount of fecal matter is 167 grammes that it will contain twelve thousand millions microbes. As to the relative number in different parts of the canal they attempted to compute by experimenting on dogs. One dog was killed two and a half hours, the other three and a half hours, after a full meal. In the stomach there were 49,000 for each cubic millimetre and in the duodenum 29,000. From the pylorus to the cæcum the number augumented progressively, so that in the jejunum there were 100,000 for each cubic millimetre. From the cæcum to the rectum there were 30,000. Contrary to the opinion generally held, their experiments prove that the acid of the gastric juice is not mortal to the microbes. Another interesting fact is the rapid decrease in the number of microbes the moment the great intestine is reached.

Diphtheritic Syphilides.—Drs. Hudelo and Bourges reported on the nature of the bacteria that are the cause of the formation of false membrane that forms on syphilides, their object being to demonstrate, if possible, an association with any single bacillus. They studied four new cases with the following results: In two cases the bacterium coli commune was found, in one the staphylococcus aureus, and in the other the streptococcus pyogenes associated with the staphylococcus aureus and albus. As they were able to isolate the bacterium coli commune in two cases, they believe it plays an important rôle in the formation of the false membrane.

Red Light on Small-pox.—It is announced that one of the small-pox pavilions at the Riverside Hospital on North Brother Island is to be fitted up with red glass windows, and with red-glass globes for the lights used at night, in accordance with the alleged discovery that the skin of small-pox patients is extremely sensitive to the violet-colored rays of light, and that it is these which give rise to the pitting. The experiments which it is claimed demonstrated this fact were made by Drs. Lindholm and Finsen, in the City Hospital, at Bergen, Norway. New York will therefore be the first city in this country to try the efficacy of the red light, which is the same as that used by photographers in developing sensitive plates.

The Central University of Kentucky.—On January 9th a new building for the Hospital College of Medicine and the Louisville College of Dentistry, which are departments of the university, was dedicated in Louisville.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, February 18, 1894.

SAMUEL B. W. MCLEOD, M.D., PRESIDENT, IN THE CHAIR.

President's Annual Address.—DR. MCLEOD, in his annual address, reviewed some of the work done by the association during the first ten years of its existence. It started its scientific work with a membership of about one hundred and nine. Meetings had been held monthly since, except during the summer. The attendance had been increasing, the average now being one hundred and forty members, or about one-sixth of the whole; the average attendance of medical bodies was about one fourth to one-sixth of the whole membership. Considering the manifold duties and engagements of medical men, the wonder was that the attendance had been so great, not that it had been no greater. There had also been an increase in the percentage of those who engaged in the scientific proceedings, either by presenting papers or participating in the discussions. An average of about nine had spoken each evening, but by no means always the same physicians. It was in the main a general practitioners' association, as it was desired to be.

So much had been said regarding higher medical education that the author thought it proper to refer to two subjects related thereto, and urged their practical application—the history and the science of correct reasoning. Historical examples of correct reasoning in medicine were found in the writings of Alonzo Clark, Watson, Bumstead, and others. The increasing influence of the profession in the community was shown by the fact that in Virginia there were ten physicians members of the legislature, by the work of health boards, etc. This influence would be still further enhanced if a cabinet officer should be appointed, as was recommended by the American Medical Association. The address also mentioned the work of the Aossciation of Railroad Surgeons and its value to science and to humanity. Its transactions contained especially valuable articles on injuries to the spine, so many cases of which came under the observation of railroad surgeons. Mention was also made of the organization of the medical staff of the national guard; also of the increase of insanity in proportion to the population. Referring to the prevention of that fatal malady, tuberculosis, he exclaimed, Let us be up and doing!

The formation of so many national and local associations was the outgrowth of the energy of our people, but there should be a combination of knowledge and unity of purpose. There were twenty national societies in America, not to mention local and State societies. It was almost impossible for one to attend all the societies in his own locality. There should be one association of which every practitioner in America should be a member—the American Medical Association.

A practical question was, What could we do the coming year to make our own association more useful? Many suggestions had been made and plans proposed, and some were under consideration; but it should be remembered that there were difficulties in the way of carrying out plans and ideas. There was always a conservative tendency, however strong might be the aggressive, and it should be remembered that the inhibitory nerves were just as important in their place as were those of acceleration in theirs.

Hydrogen Dioxide and Papoid in Pseudo-Membranous Inflammations.—DR. J. LEWIS SMITH read a paper on this subject. When B. W. Richardson began to experiment with peroxide of hydrogen in 1857 it was regarded as a chemical curiosity, and was soon forgotten after he published his first paper upon it in 1860. About thirty years elapsed when Dr. Squibb brought it prominently before the profession as the most powerful antiseptic and disinfectant. But it was found to have very disagreeable irritating properties, and believing these to be due to the acid which it contained, Dr. Smith had corresponded with Dr. Squibb, who gave the formula for making it, and as this covered six pages, it became evident that the process was not a very simple one and that some manufacturers would not take the pains to turn out a faultless article. Dr. Smith had also written Dr. Squibb whether the irritating properties due to sulphuric or phosphoric acid might not be neutralized by an alkali, and gave the formula which had been used in the New York Foundling Asylum. Dr. Squibb replied that the hydrogen dioxide had to be slightly acid if it was to be kept more than a few hours. If it were rendered neutral it would burst any ordinary bottle. But he added that Dr. Smith's proposition to add bicarbonate of soda was all right if it were done very near the time of using it. By keeping the bottle in a cool dark place, enough of the mixture could be made to last six or eight hours. For nearly a year, Dr. Smith said, they had used in the Foundling Asylum, in cases of diphtheria or pseudo-diphtheria, peroxide of hydrogen, prepared as follows: two ounces of peroxide of hydrogen in one bottle; fifteen grains of bicarbonate of sodium and two ounces of lime-water in another bottle. Take a teaspoonful from each bottle and mix together each time the nostrils and fauces were to be sprayed, or about every hour to every half hour. This did not smart nor irritate, for the alkali was sufficient not only to neutralize but to render the solution slightly alkaline. There was no agent which had such cleansing power as this in the removal of muco-pus from the fauces and nostrils, and it had given very satisfactory results at the Foundling Asylum, where, owing to the fact that the infants were farmed out, they had a great deal of diphtheria. He was unable to say how far it had solvent powers, which had been claimed for it by some, but by cleansing the surface it prepared it for the action of the papoid, of which he then proceeded to speak.

Papoid.—The digestive power of this agent had been fully investigated by Professor Chittenden, whose experiments demonstrated that it would digest coagulated egg-albumen in neutral or acid solutions; but its solvent powers were most marked in two to four per cent. of bicarbonate of sodium. Two to five minutes after the spraying with peroxide of hydrogen, papoid was applied to the diseased surface in diphtheria, being not only harmless, but believed to have solvent powers, for the results at the Foundling Asylum had been such that the sisters and physicians were unwilling to give it up. Out of 63 cases of true diphtheria, the Klebs-Loeffler bacillus having been found in all by Dr. Park, 50 recovered, which was regarded as a very favorable showing. The 13 deaths were from complications like broncho-pneumonia and acute nephritis, and not due to the primary disease. Treatment with these two agents appeared not only to destroy the bacilli, but also the toxin which produced paralysis, so that systemic infection or blood poisoning seemed not to take place if the treatment were begun early.

The author also referred to treatment of diphtheria by tincture of chloride of iron and pineapple juice, and stated that some European authorities had fallen back on vegetable acids, Professor Hennoch using acetic acid mostly.

DR. F. W. LESTER gave his experience at the Willard Parker Hospital. The great difficulty with peroxide of hydrogen had been that it was very irritating, even after free dilution. Not having been acquainted with Dr. Smith's formula, they had discarded the peroxide. They had also tried pineapple juice, giving it in teaspoonful doses, also as a spray, but they thought bichloride of mercury was better. This was used in a solution of 1 to 4,000 or 1 to 5,000 by irrigation, not by spray. The mortality from diphtheria at the Willard Parker Hospital during the four years he was there had been twenty four to twenty-five per cent., many of the cases having died soon after admission. Mild cases required little treatment.

DR. LEONARD LANDES read a paper, presumably in discussion of Dr. Smith's, but mostly on the general subject of diphtheria and its prevention.

Dr. J. Mount Bleyer said he had published a paper on peroxide of hydrogen in the Medical Record in 1886, having found it the strongest non-poisonous antiseptic then known. He, perhaps, was the first to advocate the irrigation method instead of the spray in all forms of clogged nares. He first cleansed the nostrils with lime-water, then used peroxide of hydrogen. He had not noticed irritating effects where iron, mercury, or other metallic substance had not been first used. Irrigation was made about once in fifteen minutes.

Dr. Hunter said he had been a student under Professor Chittenden, and according to his own observations and experiments, papoid had no digestive value. He expressed surprise that doctors lent the weight of their names to advertising useless remedies.

After some further discussion the next paper, "A Mechanical Demonstration of the Perfect Obstetrical Forceps," was read by Dr. James J. E. Maher, illustrated on the board and demonstrated on the manikin. A full description of the forceps and principle of their action can be found in the Medical Record, June 10, 1893.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

ALLEGED EXTRAVAGANCE OF THE ASYLUMS' BOARD—MORTALITY OF CASES IN FEVER HOSPITALS—STATISTICS IN LONDON AND LIVERPOOL—PROPOSED EXTENSION OF ST. BARTHOLOMEW'S HOSPITAL — DR. DICKENSON'S FAREWELL TO ST. GEORGE'S—TESTIMONIALS—CLINICAL SOCIETY—ADJOURNED DEBATE ON NEPHRECTOMY IN INFANCY — MULTIPLE EPITHELIOMATOUS FORMATIONS — ACUTE SUPPURATIVE PERITONITIS DUE TO APPENDICITIS.

London, February 17, 1894.

No little discontent has lately been expressed at the lavish expenditure of the Asylums' Board. Its fever hospitals have been crowded and the cry for more beds has been loud. Still the inhabitants of every district where it is proposed to plant another hospital are certain to object. The Board now proposes to spend £220,000 on another hospital at Shooter's Hill, and this sum does not include the site or the pumping machinery. No wonder the cry of extravagance has been raised, and considering this estimated cost is at the rate of £440 per bed, I cannot feel surprised if the outcry becomes louder.

There is, however, another side to the question, viz., the relative mortality of hospital and home cases. The statistics of our London fever hospitals have in this report excited much apprehension. The newspapers have disseminated alarming statements. It must, however, be remembered that several causes tend to increase the hospital mortality, one being the grave nature of many cases admitted, not a few dying within a short period. It has, nevertheless, to be acknowledged that the mortality has in many cases been seen to rise with the crowding of the wards. Attacks of diphtheria following scarlet fever increase in number whenever there is overcrowding, and are at once reduced when more space can be had. There is consequently much to be said in favor of giving plenty of space in any new hospital, and extension in this way means expenditure.

In reference to the mortality at the hospitals for infectious diseases, Liverpool seems to have obtained an enviable position. The Medical Officer of Health has just issued statistics showing that hospital treatment there has a less mortality than home treatment. Thus in the last three years the Liverpool hospital's mortality of scarlet fever was under six per cent., as against nine per cent. of those treated at home; and typhoid shows only twelve per cent. of hospital cases against nearly nineteen per cent. of home-treated patients.

Some land will probably be brought into the market for building purposes after the removal of Christ's Hospital, and it is suggested that a portion of this would be suitable for a much-needed extension of St. Bartholomew's Hospital. The out-patient department especially needs more accommodation. The college might be improved, and the resident staff and nurses have claims which demand consideration. The governors may well think it their duty to seize an opportunity of acquiring further space for their great hospital.

Dr. W. H. Dickenson's term of office as physician to St. George's Hospital having expired, he went round the wards for the last time on Monday last. Occasion was taken to furnish a demonstration of respect by a number of pupils—past and present—and friends accompanying him. Dr. Dickenson made some clinical remarks on some of the most interesting cases, one a very difficult one, mediastinal tumor, as to which he quoted Sir William Jenner's statement, that without external pulsation it is impossible to certainly diagnose thoracic aneurism. After the round the company followed Dr. Dickenson to the Board room, where he gave a brief address of farewell. Though he retires from the position of senior physician, the name will still be on the staff, for his son, Dr. Lee Dickenson, has been elected to the assistant physiciancy thus rendered vacant.

A committee has been formed to present a testimonial to Dr. Dickenson on his retirement, and will no doubt be successful. I do not much like the system of these testimonials, which has grown so much of late years. If one deserves such compliments, so does another, and it sometimes happens that retirements take place in rapid succession, and then colleagues and pupils begin to feel that a kind of tax is being levied, and some of these gentlemen can hardly afford to express their feelings through their pockets. I speak feelingly on the subject, having from circumstances been obliged to entertain a host of proposals to testimonialize my friends and acquaintances; and yet it requires real grit in men to enable them to refuse to succumb to the blandishments of promoters and secretaries of such committees.

At the Clinical Society, the adjourned discussion on the case of nephrectomy in an infant aged twenty-three months, was resumed on the 9th inst. by Mr. Bland Sutton, who held that these tumors were best let alone. He said a careful analysis of reported operations showed that more than one-half succumbed to the operation, and the lives of the survivors were rarely prolonged beyond a year, the longest being eighteen months, and of this there were only three instances. If the tumor removed by the author stood by itself it would probably be called a sarcoma, but a broad survey of sarcomata in children showed that they were characterized by peculiar kinds of tissue. Of these the most remarkable were large spindle cells transversely striated, resembling on section voluntary muscular fibres. Another form was cubical epithelium arranged as tubules or as solid columns. The presence of tubules was an almost constant feature of sarcomata arising in glands, and was due to enlargement of the tubular elements. In the renal sarcoma of infants these epithelial structures might be very abundant or almost absent. In the latter condition the tumor was very prone to contain striated spindle-cells in great abundance. It had occurred to him that tumors with abundant tubulæ might be less malignant than those in which striated spindles abounded, but further investigation did not support this view. There was nothing, in fact, in the histological characteristics of these tumors permitting anyone to distinguish between malignancy and non-malignancy. A case was recorded of a child whose tumor consisted almost entirely of the pseudo-muscle fibres, and a second case in which the histological characters were almost identical with those observed in the author's case. Both the children recovered from the operation and lived eighteen and fourteen months, respectively, so that it was obviously impossible to venture on a prognosis. The idea, therefore, that the non-recurrence of the tumor in the author's case had any connection with its histological structure, fell to the ground.

In both these cases the tumors were removed by simple enucleation out of the capsule, so that the removal of the capsule as an explanation of the immunity in the author's case must also be discarded. Considering the risks inseparable from the removal of these tumors along with the capsule, in infants, he said that they were increased two or three times when the capsule was removed as well. He doubted, therefore, whether it was desirable to attempt to get away the capsule. He thought, moreover, that there was no more reason to bring the ureter outside than there was to bring the tied end of a Fallopian tube outside, and he suggested that the tied ureter might very well be left to take care of itself. He further pointed out that surgeons removed tumors, 1, when there was pain; 2, when their presence gave rise to inconvenience; and, 3, when their existence threatened life. These renal sarcomata in children were painless, and could hardly be said to give rise to inconvenience. They certainly threatened life, but then chances of prolonging life by operation were very remote and the immediate risks of the operation great.

Mr. Alban Doran quoted Dr. Spencer's investigations, which showed that, out of one hundred and twenty stillborn infants, thirty-eight had hemorrhage in or around the kidney; in twenty-two the hemorrhage was in the capsule of the kidney, and in a few partly within and partly without the substance of the kidney. There was good reason to believe that these hemorrhages were often intrauterine, and he urged that they might prove the origin of sarcomatous growths and malignant tumors.

Mr. Malcolm, in reply, said that he saw no reason why these tumors should not be dealt with on ordinary surgical principles, and the removal of the investing membrane would be thought indispensable in operating on sarcoma elsewhere. He did not believe, moreover, that it added much risk to remove the capsule at the same time. He pointed out that the end of the Fallopian tube was surrounded by peritoneum, which was not the case with the end of the ureter; the former, moreover, was a tissue that most readily underwent repair.

Mr. Arbuthnot Lane then read an account of a case of "Multiple Epitheliomatous Formations Occurring at Different Periods in a Patient Suffering from Psoriasis in Infancy," and who had for thirty years been treated with Fowler's solution. Mr. Lane also read the notes of a case of "General Acute Suppurative Peritonitis Due to Appendicitis." On exploring the abdomen all the viscera were seen to be intensely injected, to move freely upon one another, and to be covered by a thin layer of pus, which was most obvious where the viscera came into apposition. The inflammation seemed to be equally intense everywhere, and there seemed no adhesions. On examining the right iliac fossa a very large appendix was found lying immediately internal to the anterior superior spine. It was exposed by an incision made over it, when it was found to be about as large as a thumb, intensely hard and congested, and to form part of a wall of a localized abscess cavity with adjacent viscera. It was evident that the general peritonitis resulted from the rupture of this abscess cavity. The appendix was removed and was found to be intact. It had no smell whatever, neither had the pus in its immediate vicinity. Of many cases like it this was the first he had saved. Some other members mentioned cases they had operated on and which had recovered.

A Catarrh Snuff.—The following is recommended by a writer in a French journal as a useful remedy for acute coryza:

℞. Salol	gr. xv.
Salicylic acid	gr. iij.
Boric acid	ʒ j.
Tannin	ʒ ijss.

Sig.: To be used as a snuff in the early stage of an acute rhinitis.

Anticylic Acid is the name of one of the most recent antipyretics and antiseptics.

OUR ROMAN LETTER.

(From Our Special Correspondent.)

STEAMSHIP LINES TO THE MEDITERRANEAN—RAILWAY JOURNEY FROM GENOA AND NAPLES TO ROME—HOTEL AND BOARDING-HOUSE ACCOMMODATIONS—FURNISHED APARTMENTS—CABS AND OMNIBUSES—CLIMATE OF ROME—PREPARATORY WORK OF THE CONGRESS.

Rome, February 22, 1894.

It is probable that most American physicians coming to Rome will take a steamer direct to Genoa or Naples, thereby avoiding the long and rather tedious railway journey across the Continent. There are three boats of the German Mediterranean Line which may be taken by those who wish to attend the Congress; these are the Fulda, sailing from New York on March 3d, and due in Genoa on the 14th; the Columbia, sailing the 10th, arriving in Naples the 21st and in Genoa the day following, and the Kaiser Wilhelm II., which leaves New York March 17th and arrives in Genoa the 28th, the day before the opening of the Congress. There are also three other lines to the Mediterranean, the Anchor, the Florio-Rubattino, and the Fabre, the sailing dates of whose vessels may be learned upon application to the officers of the companies in New York or to any of the agencies of Thomas Cook & Son. These boats are slower and the fares are not so high.

The journey from Genoa to Rome is made in eleven hours, the fair being $12.25 first class and $8.55 second class. There is a dining-car attached to the day train at Pisa, in which a very fair dinner may be had for 5 francs without wine. On the night-train there is a sleeping-car (not very comfortable) for which an extra charge of 16 frances ($3.20) per berth above the first-class fare is made; passengers holding second-class tickets are not admitted to the sleeping-cars. With a travelling rug and a pillow (the latter can be hired for one franc at the station in Genoa) one can be nearly as comfortable in an ordinary railway carriage as in a sleeper, provided a party of two can secure a compartment to themselves.

From Naples to Rome is a journey of four and a half to five hours, the fare being $5.60 first class and $3.90 second class. There is a sleeping-car on the night train, extra fare for berth nine francs above the first-class railway fare. The figures above given are for the regular fare, but for those who are accredited members of the Congress a very notable reduction will be made by the Italian railway companies.

There is abundant hotel and boarding house accommodation for visitors in Rome at ordinary times, but if the attendance at the Congress is as large as is now anticipated, those who come late may have considerable difficulty in finding comfortable quarters. Those who are wise will engage rooms in advance, either by writing themselves to the hotel they prefer, or by making application to the nearest agency of Thomas Cook & Son. The managers of the Congress have placed the matter of providing hotel accommodations for the members in the hands of this firm. The local agent of the company in Rome has engaged rooms and board in the various hotels and pensions for from one thousand five hundred to two thousand visitors at prices ranging from 12 fr. 50c. ($2.50) upward, according to location. Many applications have already been received, and those who wish to be sure of comfortable lodgings in a convenient quarter of the city would do well to write at once to the nearest agency of the company, stating the number of persons in the party and their relationship, whether single men or women, married couples, etc., and the price they are willing to pay. This company has also arranged for a number of excursions to Southern Italy and Sicily, before and after the Congress, and also for carriage drives and lectures upon the ruins of Rome. The rates for these excursions for independent travellers, or personally conducted parties, may be obtained upon application to any of the offices of the company in America. Those who intend to spend more than the Congress week in Rome, might find it to

their advantage to take furnished lodgings in some convenient neighborhood and get their meals at the restaurants, of which there are many in the city. A good furnished apartment of two rooms can be had for about one hundred and fifty lire ($30) per month, or fifty or sixty lire ($10 to $12) a week, if taken for a shorter period than one month. The morning coffee costs about one lire, breakfast (the noon meal) from two to four lire, and dinner from three to five lire. Coffee and wine at the two principal meals are extra, about 20 centimes for black coffee, and one to three lire for a small bottle of native wine.

Those who do not care to go out for their meals may have breakfast and dinner sent to their rooms from a neighboring *trattoria* (caterer's). Two persons may live in this way for from seven to ten lire per meal, exclusive of wine, bread, fruit, and cheese.

Furnished rooms as well as hotel accommodations may be secured through Thomas Cook & Son, but this mode of living is not to be recommended to those who do not propose to spend two or three weeks at least in Rome, or to those whose acquaintance with Italian is not equal to the expression of the ordinary wants of life.

The cabs in Rome, as in most European cities, are cheap as compared with those in New York. For a drive to any part of the city inside of the walls, the fare is eighty centimes for a one-horse open carriage, one lire for a coupé, and two lire for a two-horse carriage. When taken by the hour the rates for the three classes of conveyances are 2, 2.25, and 3 lire respectively. After sun-down the fares are about twenty per cent. higher. The regulations for drivers outside any of the gates of the city are somewhat complicated, and it is always well to make a bargain before starting. Omnibus and street-car lines run from all the principal squares in various directions, the fares being 10 or 15 centimes, according to the distance.

The climate of Rome during March is not very pleasant, because of its changeableness and the high winds. The Scirocco and the Tramontana (the southerly and the northerly winds) are contending for the mastery, and though the former conquers in the end it experiences many reverses during the struggle, and man suffers from the alternation of warm and cold, wet and dry days, almost all of them windy. The mean temperature for the month is about 50° F. April, on the other hand, is, after October, the pleasantest month in the year. There is much bright sunshine, the weather is mild and not very changeable, and the vegetation of the surrounding Campagna is glorious. One needs warm clothing, however, even then, for the air in the interior of churches and galleries is cold and, on entering them from the warm sunlight one feels a peculiar chill and is glad of the protection of a light overcoat.

The work of preparing for the Congress is going rapidly forward and everything promises to be in readiness before the visitors begin to come in. Receptions and entertainments are provided for every evening, one of them being a public reception on the Capitoline, with an illumination of the surrounding buildings and ruins, and no effort will be spared to make this congress a memorable one in the history of similar gatherings.

FISH AND PTOMAÏNE.

To the Editor of the Medical Record.

Sir: Having read in your edition of January 6, 1894, an account of what was supposed to be a "peculiar case of atropine poisoning," I am led to report a similar case which occurred in my practice only a short time ago, which was caused by eating so-called fresh fish, and which substantiates the facts quoted by Dr. A. W. Herzog in your issue of February 3, 1894.

The patient, a lady, married, of good physique, and naturally very healthy, was suddenly seized with violent pain in the epigastrium soon after partaking of her evening meal, and as the pain grew constantly worse, I was summoned in great haste to her house and found her in great agony. Her pulse was very rapid, face flushed, pupils widely dilated, so much so that the first thing she said to me was, "Oh, doctor, I can't see." She had also vomited several times, and upon inquiring as to what she had eaten for supper, she told me they had fresh fish, of which she had eaten quite heartily, and in less than a half-hour was seized with this pain, which gradually grew worse. I at once made the diagnosis of ptomaïne poisoning caused by eating fish which was not very fresh, and treated her accordingly. She made a good recovery in about three days, and has been well ever since.

Her husband also ate a little of the same fish and had some of the same symptoms, but not so marked.

Now, the point which this case illustrates very clearly is, that ptomaïnes do cause nearly the same symptoms as atropine when taken into the stomach in sufficient quantity to enter the circulation, and that our friend, Dr. H. H. Seelye, of Amherst, Mass., must have been mistaken in his diagnosis.

L. C. Osmun, M.D.

Hackettstown, N. J.

THE THERAPEUTIC VALUE OF SARSAPARILLA.

To the Editor of the Medical Record.

Sir: In an editorial of your issue of February 17th, you deny the existence of any ingredients in the official sarsaparilla root to which medicinal activity may be referred. In thus denouncing an old remedy without proper investigation, you do sarsaparilla injustice.

On page 53 of Maisch's "Organic Materia Medica," you will find a reliable analysis of the drug, and further, that it contains one-fifth of one per cent. of a glucoside called parillin, and that it is irritant. This irritant action might be made use of therapeutically, in large doses, as an emetic and purgative, which action is an effort of the vital forces to throw out an offending substance. In smaller doses vomiting and purging is not induced, the parillin is absorbed, and the vital forces find it necessary to excrete the irritant substance through the various emunctories of the body, viz., the kidneys, skin, lungs, etc. During this excretory process it is not unreasonable to suppose that the activity of these special organs is greatly increased, and that other offending substances are at the same time thrown out of the body, and thus the old empirical use of the remedy in rheumatism, syphilis, skin diseases, etc., is justified and its beneficial action explained.

This is true not alone of sarsaparilla, but of a number of other official drugs also, as for instance, xanthoxylum, stillengia, taraxacum, senega, apocynum, and a host of others. The presence of these excretory stimulants in the Pharmacopœia is therefore not without good reason.

Pittsburgh, Pa. Adolph Koenig, M.D.

ARE DISPENSARIES TO BE OR NOT TO BE?

To the Editor of the Medical Record.

Sir: In order to come to a mutual understanding about the much-ventilated dispensary question, we must only ask ourselves, "Is the public benefited by their existence?" The question whether one or the other physician is pecuniarily injured by them should not and must not be considered.

No doubt, in most cases patients derive much benefit by going to dispensaries, hence they are good, and what is good has a right to exist and will exist in spite of all aggression. The public in general calling at dispensaries belongs to the middle and lower classes; but let me say right here that I am well aware of the fact that some dispensaries are also frequented by people who can very well afford to pay a doctor or a specialist; but these are few and the exception, for they fear to be seen by somebody who knows them. Every dispensary physician will admit that by far the greatest portion of patients consists of incurables or chronics, some of whom had their doctors until they found themselves *vis-à-vis de rien*.

The specialist in the dispensaries also knows that very few of his clients would be able to pay his price at his office, and for certain reasons he would not care to have them all call at his office for free treatment.

Again, there is a certain class of people going to dispensaries who suffer from imaginary diseases, others to have the diagnosis of their family physician verified, and others are sent to the specialist in the dispensaries by their family physician, and their number is legion.

We, as physicians, cannot blame people who go to a dispensary, because it is not more than right for any woman to take a sick child to a place where it is treated free, if by the operation one and a half to two dollars can be saved, which is possibly all the husband gets for ten hours' hard work.

On the other hand, most all people understand well enough: 1. That in going to a dispensary they cannot be treated as carefully as when they call their family physician at home, and he explains things thoroughly. 2. That sitting for hours among a lot of sick people, a contagion of some kind may be acquired. 3. That if patient should get worse, in most all cases the dispensary doctors cannot be procured, as they mostly live out of their way.

The criticism, then, exercised toward the dispensary doctor, and dispensaries in general, by the doctor who is called in, is in most cases an unmerciful one. Even if the patient should die one or two weeks afterward, the dispensary is blamed for it.

The public in general, in this country, is as a rule very impatient. If there is a patient in a family this fact is discussed at once on the street, in the stores, and everybody recommends their own doctor. In some cases all are called in turn, each one abusing his predecessor. If the patient, in spite of this medical tourney, gets well, the last attending physician gets the credit; if the patient should die he is called his murderer, and this is his recompense for his ungentleman-like behavior toward his brother-practitioners.

Now, fellow practitioners, let us be satisfied that: 1. There is yet a certain class of people who ought to go to dispensaries, but who have too much pride about the matter. 2. That we are still called in in certain diseases, as eruptive fevers (small-pox, typhus, etc.), inflammatory diseases, confinements. 3. And that all doctors with now gilt-edged practices had to commence small, that after they have gone the way of all flesh, that there is hope for us, the younger generation.

The great howl of many doctors (who do not belong to dispensaries), that these institutions are the ruination of their practice, is nothing but egotism and jealousy toward men who, by having worked for years in dispensaries, have acquired a good standing among the profession, and who have derived possibly therefrom some material benefit.

What do we learn from the aforesaid? 1. That the number of physicians now existing is more than enough to cope with all the ailments affecting humanity for the next ten years. 2. That, if a young man studies medicine in order to acquire wealth, he makes a great mistake. Only after years of thorough studying and hard work will he be able to make a living for himself and family. 3. That in order to become known to the public he will have to join one or more dispensaries, or must have good social qualities, or must start a dispensary for himself. 4. That a Thomas or Emmet, a Virchow or Billroth, a Lister or Harvey, and a Charcot or Pasteur, are not born every day.

Respectfully,

H. F. Eichacker, M.D.

66 Cannon Street.

Coca.—The quantities of coca exported during 1892 were as follows: London, 2,672 pounds; Hamburgh, 932 pounds; New York, 221 pounds. The total amount was 3,825 pounds, valued at 400,000 francs. Coca leaves are exported principally from the province of Huanuco in Peru.

THE RELATIONS OF VEGETABLE DIET TO GROWTH.

To the Editor of the Medical Record

Sir: In reply to the criticism of George R. Elliott, M.D., which appeared in your issue of February 10th, kindly permit the following:

In writing my essay it was not my intention to be the propounder of a new theory but to give the results of: first, observation, then research; I have observed from nature, searched for proof in chemistry and brought facts from ethnography.

Have I really made such statements in my essay as Dr. Elliott pretends to have found? "Neither climate nor heredity directly influence . . ." I said; the word "directly" he seemingly overlooked.

At the end of his criticism he says: "No amount of vegetables would make the Esquimau large." I spoke of vegetables only as they contained earthy salts, which produced height; it is not the vegetable but the earthy salts it contains.

In how far can Dr. Elliott see a *direct* connection between climate and stature; upon what physiological process would he like to base his opinion? Is it probably due to a reflex action or a sympathy between that frigid Boreas and those unfortunate Greenlanders? That climate has its share in influencing man's stature is unquestionable, but it acts indirectly. A cold climate restricts or prevents the entire plant life from developing or growing and the poor inhabitants have to take refuge in other eatables.

Regarding the Patagonian, L. Figuier ("The Human Race") says: "If the poor little one is judged worthy to live (elsewise the new-born is exposed by its parents) its mother nurses it until it is three years old; and according to Ratzel (Völkerkunde), they subsist on the products of the chase, wild fruits, roots, and berries. We see, then, that the fundamental three-years' milk course is supplemented later by fruits, roots, and berries. They have consequently received in infancy the necessary foundation, and later they live on a mixed diet and not exclusively on meat.

Concerning the North American Indian, Ratzel says: "of roots they eat the Levisia rediviva, Apios tuberosa, Lupinus littoralis and several species of Oenothera. Of the edible mushrooms they like the so-called 'Indian potato,' Lycoperdon solidum, which occasionally weighs as much as thirty pounds. As salads and vegetables they eat the leaves of various kinds of Leontodon, Chenopodium quinoa, Phytolacca decandria, and Caltha palustris . . . a favorite food of the Wintun is clover."

From the report of the Smithsonian Institution for 1885–86, page 41, I beg to quote: "The accounts of some of the early explorers in the Southern United States mention cornfields of great extent; the Iroquois and some of the Ohio valley tribes also raised corn in great quantities." In the report for 1888, "On the Indians of the Northwest Coast," it says, page 276, "Fish and berries form the staff of life among the Indians of this region. Any kind of meat of wild animals is eaten when procurable. Roots, herbs, berries, and snails are among the luxuries of the summer season. Raspberries, salmon berries, salal, and thimble berries abound late in the summer. Some of these are collected and dried for winter's use, forming, with the dried fish, the principal winter's supply. . . . The inner bark of the spruce and hemlock forms an important part of the food supply of the Haida, Tlingit and Tsimshian; the southern Indian eats pine bark."

It seems, then, that neither the Patagonians nor the North American Indians are indifferent to Flora's rich donations. Why they should prefer hunger rather than reach after the voluptuous looking fruits and other products of the earth abundantly surrounding them, would be very strange, but fortunately it is not the case.

Dr. Elliott finds a connection between barbarism and inferiority of size. He also speaks of the Khirgiz, Kamstschadales and the Bushman as, "small irrespective of

diet," and of the Ostiaks that they are short-legged notwithstanding their being by no means flesh-eating tribes; but his statements are opposed by R. G. Latham, L. Figuier, and F. Ratzel, who describe those tribes as distinctly carnivorous.

But besides, it is not the mere fact that because one is a vegetarian he must be tall, or *vice versa*. All depends upon at what age one has been carnivorous or herbivorous; once the epiphyses have been united by bone to the apophyses the stature remains. In reference to the large heads of the herbivora, I admit not having expressed myself clearly. I meant to differentiate the cranium proper from what represents in them the face; it is this latter part that is so much more developed in the herbivora.

Concerning the rhinoceros as an example of herbivorous brevity, they seem to conform with our old *nulla regula sine exceptione*, but nature knows no exceptions, there must exist some cause of which I am yet ignorant. All is well that ends well. After Dr. Elliott eloquently refuted my statements, after he cut me down on the climate, Patagonian, North American, Indian, Khirgiz, and all their sisters and their cousins and their aunts, he finally says: "Through the modern process of selection and training the dray-horse is made to lose his gigantic digestive apparatus, etc. . . ." *Si tacuisset!* So he finally contradicts himself, saying that the artificial training of the dray-horse makes him change his stature in spite of the climate, altitude, and heredity.

Once more allow me to dwell, in brief, on climate. While climate is quite a factor in affecting man's stature empirically, yet it is never the direct and immediate cause; while the Esquimau is forced by reason of his climate to live on animals, his land not giving him any vegetables, save various species of moss, he is not necessarily excluded from obtaining a vegetable diet; while his climate forces him to live packed together in a highly vitiated atmosphere impregnated with disease, yet this condition is not unavoidable. No man can be, unavoidably or irremediably, forced by nature; nature must always yield to science.

MARK I. KNAPP.

NEW YORK, March 1, 1894.

PERMANGANATE OF MORPHIA AS AN ANTIDOTE FOR MORPHINE-POISONING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the MEDICAL RECORD of February 17th I see an article from Dr. William Moor, of New York, claiming that potassium permanganate is an antidote for morphine poisoning. Several weeks since an account of the doctor's daring deed of swallowing three grains of morphine and then four grains of the potassium permanganate appeared in a New York paper; subsequently an account of several experiments made by him, and a number of other physicians, upon rabbits with these drugs appeared in the same journal. It was claimed that these experiments satisfactorily proved the efficacy of permanganate of potassium as an antidote in cases of morphine poisoning.

Of course a newspaper is an unreliable source from which to gain information regarding scientific experiments. However, the doctor refers in his article to encouraging experiments upon rabbits confirming his beliefs, hence, naturally, some credence is given to the newspaper article. According to this report one grain of morphine was given to a rabbit by the mouth through a flexible tube; a gastric fistula was then established, and within about three hours the animal was dead.

Rabbit No. 2 was given a similar quantity hypodermically, and in fifteen minutes three-fourths of a grain of permanganate of potassium, and in fifteen minutes more one-third of a grain more of the antidote was similarly administered, and within two hours the rabbit had practically recovered from the effects of the morphine. The same result was obtained, so the account goes, in two other rabbits to which had been administered by the stomach two grains and five grains of morphine respectively, the latter being termed the *pièce de resistance* "of the day," the morphine poisoning yielding readily to the influence of the permanganate of potassium. Another article brings a corroboration of Dr. Moor's investigations from several St. Louis physicians, who used dogs as their subjects, giving as a maximum dose by the mouth six grains of morphine.

Noting these interesting accounts I was led to make some personal investigations along this line, and as yet must acknowledge that my results have not been as satisfactory as those reached by others, though my eyes have been opened to the comparative harmlessness of exceedingly large doses of sulphate of morphia in certain of the lower animals. So far I have been unable to discover a fatal dose of morphine for either a dog or rabbit, and hence cannot accept anything as a "sure cure" until the drug first is proven poisonous to the animal experimented upon. I do not mean to say that dogs and rabbits cannot be killed by morphine, for, of course, they can; but I do say that the doses which these articles referred to state that the physicians have used will not kill either dog or rabbit, and hence, no one can know whether their recovery has been due to the so-called antidote or to natural causes.

On February 15th, in the presence of Drs. M. L. Wood and J. H. Noftel, of this city, I gave a dog, weighing ten pounds, three grains of sulphate of morphine by the mouth; in forty-six minutes she had a violent convulsion attended by a complete paralysis of the hind legs. Two grains of permanganate of potassium were administered, and in fifteen minutes a third grain was given hypodermically. After about twenty or thirty minutes the dog showed but little evidence of the morphia poisoning, except the continued paralysis of the hind legs, which lasted until the following day.

February 16th, two grains of morphine were given to a medium-sized dog, subcutaneously, and in three quarters of an hour decided symptoms of coma were apparent. One grain of the antidote, hypodermically administered, and followed by a second grain in fifteen minutes, was given. In about half an hour the dog was much improved and in about three hours was well, except the partial paralysis of the hind legs.

On February 17th, dog No. 1 was given three grains of morphine hypodermically and suffered much as the previous dog. No antidote was given and the dog recovered completely, though perhaps not so rapidly as before.

At the same time dog No. 2 was given six grains of morphine hypodermically. He experienced less sopor, though the general nervous effect seemed more profound than when two grains were administered. After about six hours the dog seemed perfectly well. On February 17th, in the presence of the Montgomery County Medical and Surgical Society, I injected hypodermically into a dog weighing fifteen pounds eight grains of sulphate of morphine. Immediately he showed signs of somnolency followed by excessive nervous excitement and paralysis of hind legs, but in a few hours passed from under the influence of the drug, eating heartily the next day. On the 19th the same dog was treated to a hypodermic injection of the enormous dose of twenty four grains of morphine; he suffered much as before, and to-day, the 20th, he is apparently as well as ever except some continued nervous excitability. Experiments upon rabbits point to similar results.

On February 17th I administered hypodermically one grain of morphine to a small rabbit, and in three hours, noting but little effect other than drowsiness and slowed respirations, the dose was repeated. The animal, without any alarming symptoms, made a perfect recovery in a few hours without antidotes. The same day I gave another rabbit three grains of morphine subcutaneously without lethal effect, and on February 19th I gave a third rabbit five grains hypodermically, and after a few hours of semi-drowsiness and slowed respiratory action he made a com-

plete recovery, and is now with the other rabbits and dogs in my barn-yard awaiting another treat of morphine.

According to the cases referred to by Dr. Moor the only death occurring was a rabbit given one grain of morphine through the mouth, and subsequently a gastric fistula was established. In my opinion if the doctor had discovered an antidote for the fistula instead of for morphia, his rabbit would not have died. My experiments have convinced me that one grain of morphine, either introduced through the mouth or hypodermically, will not kill a rabbit, furthermore, five grains subcutaneously will not do so. In dogs, as in rabbits, small doses seem to produce somnolency. However, they bear very large doses of the drug, six, eight, and then twenty-four grains, hypodermically administered, in dogs weighing not over fifteen pounds, have failed in my hands to produce any very alarming symptoms.

The largest dose reported followed by recovery in dogs, so far as I have been able to find, is six grains given by the stomach. This is surprising to me, since dogs are in such common use for experimental purposes.

During the past week, in company with several other physicians, I have made a number of experiments bearing on this subject, which I purpose tabulating and forwarding to your valuable journal within the next week. I write this not to criticise adversely Dr. Moor's apparent discovery, for, from personal observation I am led to believe that there is something in what he claims, but I wish to suggest to those who may see fit to prosecute these investigations further, to first ascertain the poisonous dose of morphine for the animal experimented upon before publishing an antidote therefor; and, secondly, I wish to note the unusually large doses of morphine which rabbits and dogs will bear with but little inconvenience.

GLENN ANDREWS, M.D.

MONTGOMERY, ALA., February 21, 1894.

Therapeutic Hints.

Bromidrosis. — Internally give ℥viij. tinct. belladon. in ʒ ss. fluid extract ergot, three times a day; externally, use on the body the following powder several times daily:

℞.	Salicylic acid	drachms	3
	Boric "	oz.	ʒ
	Zinc oxide	"	½
	Powdered starch	"	5
	Ottar of roses	minims	20

Pleuritic Exudation.—To prevent extension of exudation: Absolute rest in the recumbent position, until temperature has been normal for eight days, the heart and respiration being the guides as to increase of fluid. No movement to be permitted for the purpose of examining the chest or for any other object. Striking results reported.

Purulent Ophthalmia.—Carefully wash the eyes first; then:

℞.	Corrosive sublimate	gram.	0.02 (gr. ⅓)
	Syndenham's laudanum	"	0.05 (℥ viij.)
	Distilled water	"	150.00 (ʒ v.)

A few drops to be instilled every two hours, then every hour. No cauterization to be employed. Catarrhal symptoms soon begin to disappear. If slight conjunctivitis remain:

℞.	Sulphate of zinc	gram.	0.05 (gr. ¾)
	Boric acid	"	0 04 (ʒ j.)
	Distilled water	"	100 00 (ʒ iijss.)

To be used every two hours, in the same manner as the previous solution, and alternating with it.

Cardiac Weakness in Arterio-Sclerosis.—The distressing palpitation to which this gives rise may be greatly relieved by the following:

℞.	Chloral hydrate,		
	Sodium bromide	āā gram.	4 00
	Codeine	centig.	0.10
	Water,		
	Syrup of orange peel	āā gram.	45

M. Sig.: Take a dessertspoonful every two hours till the heart is quieted.

Sciatica.—

℞.	Opii pulv.,		
	Ipecac pulv	āā	gr. xij.
	Sodii salicylat		ʒ j.
	Ext. cascaræ fl		q. s.

M. Div. in pil. No. xij.
S. One or two pills for a dose.

—DR. BENJAMIN WARD RICHARDSON.

Fermentative Dyspepsia.—

℞.	Olei creosoti		℥ xij.
	Spts. tennoris		ʒ ss.
	Ammon. benzoat		ʒ ij.
	Glycerin		ʒ vi.
	Infus. caryophyl. q. s	ad.	ʒ vi.

M. S.: Tablespoonful in a glass of water.

—DR. B. W. RICHARDSON.

Atrophic Rhinitis.—

℞.	Thymol		0.08 ctgm.
	Alcohol,		
	Glycerine	āā	6 gram.
	Distilled water		3 gram.

M. Apply with atomizer.

Night Sweats of Phthisis.—

℞.	Sulphate of atropine		0.0005 gram.
	Sulphate of zinc		0.12 gram.
	Gallic acid		0.12 gram.
	Creosote		10 gtts.

M. Div. in pil. No. v.
S. One pill thrice daily.

Hæmoptysis.—

℞.	Gallic acid,		
	Ergotine	āā	1 gram.
	Distilled water,		
	Syrup	āā	25 gram.

M. S.: Teaspoonful every two hours, or, if the bleeding is severe, every hour. Better results follow the use of the ergotine in this mixture than when it is given alone hypodermatically.

Chapped Hands and Face.—A most excellent remedy for chapped hands and face, and one that, if properly used, will cure the most painful cases in from twelve to twenty-four hours, is compounded as follows:

℞.	Tr. benzoin co		℥ x.
	Alcohol		ʒ ij.
	Aqua rosæ		℥ xxx.
	Glycerine	q.s. ad.	ʒ j.

M. Sig.: Apply to chapped surfaces at night, after they have been washed with soap and warm water, and thoroughly dried.

A second application is rarely required. This remedy is equally efficacious in the treatment of fissured, bleeding, and sore lips.—W. P. SPRATLING, M.D.

Escharotic Paste for cancer, lupus, etc.—

℞.	Wheat-flour		7 ounces.
	Starch		2 ounces.
	Corrosive sublimate		15 grains.
	Pure iodol,		
	Croton chloral,		
	Bromide of camphor,		
	Crystal carbol. acid	āā	2½ drachms.
	Oxide of zinc		7 ounces.

Water, enough to make a homogeneous mass of the consistence of putty.

—FELIX.

Scrofula.—Iodoform may be given to young children for a long time. It is to be preferred to iodine and iodides.

℞.	Iodoform		gr. jss.
	Mellis		ʒ iv.

—BESNIER.

Bronchitis with difficulty in coughing up secretions.—

℞.	Ol. terebinthin		ʒ ij. to ʒ iij.
	Mucil. acaciæ		q. s.
	Aq. cinnamomi		ʒ j.
	Aquæ	q. s. ad	ʒ vj.

M. Sig.: A tablespoonful in a little water every four hours.

Filaria Sanguinis in chyluria may be driven out of the system by thymol gr. j. every four hours, with subsequent doubling of the dose.—*Bul. gén. de Thér.*

New Instruments.

A COMBINATION TEST-CARD.

By EDWARD B. HECKEL, A.M., M.D.,

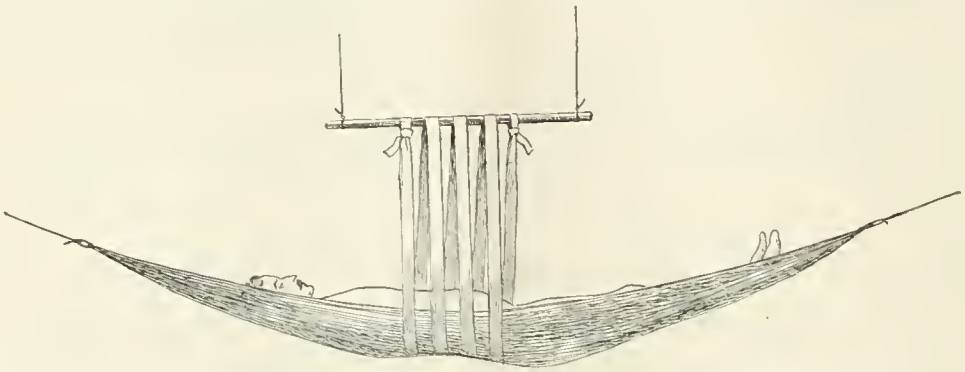
PITTSBURGH, PA.

LECTURER ON DISEASES OF THE EYE AND EAR AT THE WESTERN PENNSYLVANIA MEDICAL COLLEGE (MEDICAL DEPARTMENT OF THE WESTERN UNIVERSITY OF PENNSYLVANIA), ETC.

In the issue of November 12, 1892, of the New York Medical Record appeared a wood-cut and a description of a combination test-card designed by Dr. Hunter, of New York. The *raison d'être* of such an apparatus for accurate work is too self-evident to require comment or endorsement. The writer simply desires to briefly describe an apparatus such as he has used in his office for about one year, with perfect satisfaction, and which has entirely eliminated the heretofore often heard expression, "I don't think I could make out that line if I didn't know the letters." It consists of a tripod upon which revolves a triangular box, presenting three flat surfaces, provided with grooves for the reception of strips of cardboard. There are nine of these spaces for the corresponding nine rows of letters from cc to x, inclusive, on each side, thus giving three distinct surfaces which can be presented to view by simply turning the triangular box. The one in use (see Fig.) is provided with ten distinct sets, including pot-hooks and German letters. This gives ninety rows of letters, which when used, nine at a time, enables us to make almost an infinite number of combinations; enough, at least, to outwit the memory of our brightest patients. In appearance it is neat, in structure simple, and can be moved about with ease. It is constructed of pine wood, and finished with dull black. The writer is indebted to Messrs. Feick Bros., for their co operation.

502 Penn Avenue.

THE HORIZONTAL POSITION FOR APPLYING PLASTER CAST.



By T. W. SLOAN, M.D.,

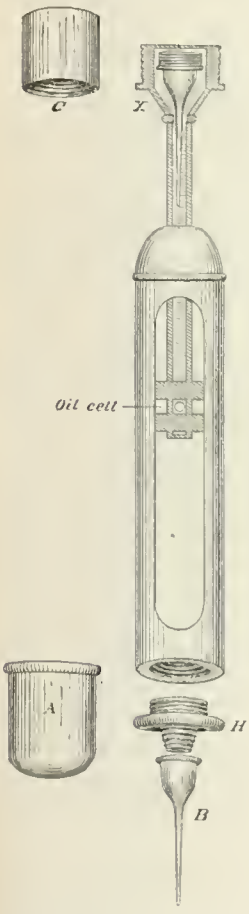
SEATTLE, WASH.

Since the time when Dr. Sayre first presented to the medical profession his apparatus for suspending the patient for application of the plaster cast, I am not aware that any other method has been practised to any great extent, for notwithstanding the number of objections to suspension in the upright position no one has succeeded in devising a means by which a cast can be properly applied while the patient is resting in the horizontal position. With this object in view Dr. Dory offered, as a substitute for the suspension apparatus, the hammock; his method being to place the patient in the hammock, face downward, and after applying the dressing around the hammock, and allowing it to harden, the hammock was cut off at the upper and lower border of the cast. The objections to this method are obvious, for in addition to its being almost as uncomfortable to the patient as the upright position, the sagging of the hammock would tend to produce, rather than correct, posterior curvature, so the suspension apparatus of Dr. Sayre still held possession of this particular domain without a rival. The objections to the hammock are, that although it be stretched very tight, it sags under the weight of the body, which assumes an abnormal position, and the cast holds it permanently in that position, and when the patient is upon the back, the tension upon the hammock holds the plaster bandages away from the lumbar and lower dorsal regions, and the natural concavity of the back is not preserved in the cast.

For the purpose of overcoming the first objection to the hammock, Dr. Milliken (Medical Record, December 30, 1893, describes an apparatus by which a greater amount of tension can be produced than is possible with the ordinary hammock, which he calls the hammock splint. The ingenious device will undoubtedly correct to a great extent the sagging that is caused by the weight of the body when placed upon a hammock; but unfortunately for this apparatus, neither back, front, nor either side of the human anatomy is constructed so as to fit a plane surface. He will undoubtedly be successful in fitting a cast to his splint, but I doubt very much if it will fit the patient.

A few months since I had occasion to apply a plaster cast in a case of lateral curvature in a child, and I found that the deformity, though easily overcome by placing the patient across my knees, was not so corrected by suspension, though prolonged to the extent of causing decided discomfort to my patient. I then procured a child's hammock, and placed the patient on her back in the hammock, the latter being made moderately tense. By making traction upon the foot of the side to which the curvature was inclined, the shoulders being held by an assistant, the vertebral column was brought into line easily. The sides of the hammock were then trimmed off so that it would only encircle about half of the patient's body. A horizontal bar was suspended at convenient height above the patient, to which was attached the end of a gauze bandage. Three or four turns of the bandage were taken around the patient's body and up over the bar, leaving between each turn around the body a space of two inches. This procedure not only supported the weight of the body and held it in its natural position, but it caused the hammock, with the dressing to be applied over it, to fit the concavity of the back snugly. The plaster bandages were then applied, and the patient left in that position for two hours, at the expiration of which time the cast was found to be quite firm. The patient was then placed upon her feet, and the hammock cut off even with the upper and lower border of the dressing, and the suspension bandage was clipped off where each piece emerged from the cast. The turns of the suspension bandage are not in the way of

applying the plaster bandages, and when the dressing is completed they are compressed into mere cords where they emerge from the cast.



Since this time I have made use of the hammock, with the suspension apparatus above described, and each time the result has been so eminently satisfactory that I am confident anyone who gives this method a fair trial will be convinced of its merits. The suspension apparatus, consisting of a horizontal bar and a gauze bandage, effectually overcomes the principal objections to the hammock, for it at once prevents the hammock from sagging and makes the cast fit the concavity of the back in the lumbar and lower portion of the dorsal region. In posterior curvature the suspension should only be sufficient to hold the hammock in place, thereby allowing the weight of the body to correct the deformity, whereas, in anterior curvature the turns of the bandage must be drawn more or less tightly according to the amount of support required in each individual case.

A NEW HYPODERMIC SYRINGE.

By WILLIAM L. STOWELL, M.D.,

NEW YORK.

Although the market is full of hypodermic syringes, I have spent much time in arranging a new one which I venture to present.

It is of small compass, and without bottle, box or case. It is antiseptic and always in working order.

Referring to the illustration, *A*, is a chamber for morphine tablets. Its cap screws on part *H*, which allows the use of a needle with inside threads. A needle with outside threads will fit immediately in the syringe, where the tablet may also be dissolved. The essential part of the instrument is the hollow piston-rod of Messrs. Lincoln & Luchesi. The packing of this rod is in two portions; the intervening chamber is always full of oil from a small hole in the hollow rod. The rod ends above in a cup, X, to hold the needle when not in use. The cap *C*, is then screwed on, making the closed instrument three and a half inches long.

Castor is the best oil to use because it is the most viscid. Having nearly filled the cup of the piston, add a few drops of carbolic acid and you have an antiseptic oil in which the needle remains free from rust. The piston will never dry if a few drops of oil are put in the cup twice a year.

28 West Thirty-sixth Street, December 15, 1893.

Liability of the Husband for Medical Attendance upon the Wife.—President Judge Hanna, in delivering the opinion of the Orphans' Court of Philadelphia, in the case of Waesch's Estate, says: The liability of the husband for medical attendance upon his wife, even although she has a separate estate, is too well settled to admit of argument. He is primarily liable, and her estate is liable only in case he be insolvent. If any balance then remains for distribution, the expenses he should have paid will be deducted from his distributive share.

A NEW VAGINAL SPECULUM WITH CONSTANT IRRIGATION.

By A. A. HERZFELD, M.D.,

NEW YORK.

ASSISTANT TO THE CHAIR OF CLINICAL PATHOLOGY AT THE NEW YORK POLYCLINIC, FORMERLY VOLUNTEER ASSISTANT AT THE FRAUENCLINICS OF DRESDEN AND MUNICH.

The subject of vaginal irrigation through specula originated with Dr. Henry Greenway, of Plymouth,[1] who constructed an irrigating tube, with the view of irrigating a large surface of the vaginal mucous membrane. The instrument consisted of four rods about six inches long, united at their vaginal end; at the introitus vaginæ they were riveted into a cylindrical ring, thus forming a foot of fenestrated speculum. In the central axis of this instrument the irrigating tube passed up to the cervix. At the lower end of the tube the rubber hose was attached, which connected the instrument with the irrigator. Four rows of openings gave vent to the irrigating fluid, which, irrigating the cervix and a large surface of the vaginal mucous membrane, escaped through several holes at the sides of the instrument.

Dr. Holzer, of Franzenbad,[2] made use of the Mayer hard-rubber speculum in the construction of his "permanentes Douchebad des Uterus." Through the middle of the speculum passes the irrigating tube to the external os of the uterus. The instrument is closed by a plate in front, so as to cause a collection of the irrigating fluid in its interior. The fluid escapes through small holes at the sides of the instrument. This instrument is also fenestrated so as to allow a free irrigation of the vaginal mucous membrane. For constant irrigation the instrument is very valuable. For this purpose it is fastened by strings around the patient's body. Although a speculum is used to obtain this result, the instrument is no speculum in the true sense of the word, as its inlet is closed by a plate and we cannot see what we are doing. The credit for obtaining this result, combining the vaginal speculum with satisfactory irrigation, belongs to Fritsch, of Breslau, (now Bonn). In the construction of his instrument, he made use of the anterior plate of a Simon's platten speculum. By a very simple and ingenious device a constant irrigation is obtained through this speculum for diagnostic purposes as well as during operations on the perineum, cervix, posterior vaginal wall, etc. In the construction of my apparatus, I have made use for the time of a bivalve speculum, which can be converted into a single blade speculum, and in both of these positions irrigation can be obtained through it. The instrument is constructed on the plan of the Graves speculum. The upper blade is the one through which the irrigating fluid passes, this blade being double.

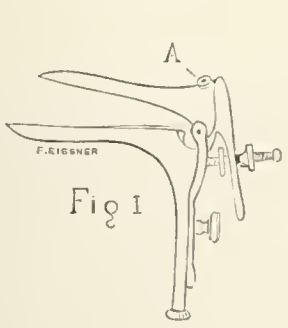


Fig I

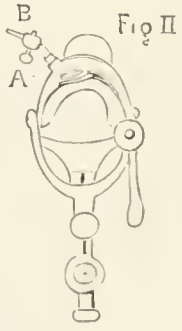

Fig II

At its point there is a narrow slit-like opening for the discharge of the irrigating fluid. The fluid enters the upper blade through a stop-cock (Fig. II, B), which is attached to it by means of a bayonet lock (Fig II., A). The amount of fluid entering is regulated by the stop-cock. In the position as bivalve the stopcock is placed on the left upper corner of the blade, so as to be entirely out of the working field. The lower blade corresponding

[1] Lancet, May, 1879.

[2] Illustrierte Vierteljahresschrift der aerztlichen Polytechnik, April, 1880.

to the posterior vaginal wall is 0.5 c.m. longer than the upper blade. On it the irrigating fluid collects and is carried away through a tube which represents the handle of the instrument. To avoid overflow of the liquid on entering this tube, a plate is attached behind the inlet of tube (Fig. II) in front of which the liquid collects. The screw at the middle of the handle of the instrument allows it to be taken apart, so that it can be used as a single-blade speculum, or the posterior blade can be used by itself, or the instrument can be arranged into a speculum assimilating Sims's. In this latter arrangement the posterior blade is used as a handle, the anterior blade supporting the anterior vaginal wall (patient in dorsal position) and permitting the irrigation of cervix, posterior, vaginal, and perineum. In this position I have made use of the instrument during the repair of a lacerated perineum. The stopcock is placed now to the right of the operator. The screw which holds the two plates together in bivalve position, permits their separation so as to adopt the speculum to the lumen of any vagina (Graves). The handle of the upper blade runs on a screw arrangement, permitting the separation of the upper from the lower blade after the introduction of the instrument into the vagina, and is steadied by two screws; one anterior, one posterior to the handle (see Fig. I.), so as to allow the adoption of this blade to any position of the anterior vaginal wall. This arrangement is particularly useful when the patient is in the dorsal position, and the instrument is used as "Sims's," the anterior blade holding up the vaginal wall.

I would like to express my gratitude to Dr. Vineberg for his kind interest, and to Dr. Charles G. Kerley and Mr. Eissner for their valuable aid in the construction of the instrument.

211 West Twenty-fourth Street.

Acting Assistant Surgeons of the United States Army.—Dr. T. Nagle has recently written a reply to the ruling of the War Department in the matter of the standing of the acting assistant surgeons of the army who served in the late civil war. According to the present status such officers are deprived from participating in the benefits of the act of 1863, which confers medals of honor on "officers, non-commissioned officers, and privates as have most distinguished themselves in action." Dr. Nagle has appealed from this ruling, and has been supported in his appeal by an opinion from the attorney-general, but the assistant secretary of war will not accept such an opinion, and claims that it is optional with his department so to do. Dr. Nagle's claim is that the acting assistant surgeons are just as much entitled to medals for distinguished bravery as are any other of the medical officers of the army during the civil war. The contention of the War Department is that "acting assistant surgeons were then, as they still are, necessarily assimilated, as to their duties, pay, and status to assistant surgeons of the army. So, when serving with the forces in the field they were subject to military discipline and to the jurisdiction of courts-martial, under the provisions of the 60th (now 63d) article of war. But they were neither commissioned, nor were they authorized or recognized by any legislation of Congress as a part of the military establishment. They were creations solely of army regulations and general orders, which are executive mandates and wholly powerless to constitute persons officers of the army. Those regulations and orders could and did authorize commanders to contract to 'employ' civil or 'private' physicians, to render professional service in connection with the medical department of the army, but could not and did not commission them or make them officers of regulars or volunteers."

Recognized After Many Years.—Colonel B. J. D. Irwin, Medical Director of the Department of the Missouri, U. S. A., has been awarded the bronze medal of honor which Congress, by an Act passed in 1864, authorized the War Department to confer upon officers or enlisted men for any specially meritorious conduct in action. Dr. Irwin has waited long for this recognition, for the act for which the medal is granted was performed almost thirty-three years ago. Colonel Irwin was then a young surgeon with the rank of second-lieutenant, and was serving in New Mexico, where the Apaches were on the war-path. The medal is awarded for bravery in fighting the redskins.

THE TREATMENT OF URÆMIA.[1]

BY BEVERLEY ROBINSON, M.D.,

CLINICAL PROFESSOR OF MEDICINE AT THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

IT is admitted by many scientists, as well as practitioners of medicine, that there is a certain amount of doubt in regard to the essential cause, or causes, of uræmia. Nevertheless, there is a degree of acquired knowledge in this regard which enables us to interpret uræmia, when it becomes manifest in an acute or chronic form, with a clearer knowledge of the elements involved than formerly. We no longer believe that urea or ammonia causes it. We are convinced that the poisons retained in the blood are numerous. We know that cold and errors of diet are important factors in developing it, when with care in respect to exposure and food the renal lesion might not produce disquieting symptoms during long periods. This being admitted, the preventive treatment of uræmia is very important. If a patient who has Bright's disease is exposed to cold and subsequently develops symptoms of uræmia, we must primarily carry out the most rational indications. The first of these is to give warmth, by means of a warm room; or better still, a warm bed, when the symptoms are at all acute. In addition, it is wise, particularly if the skin is dry and inactive, to help restore the cutaneous function by a hot-air bath, or a hot-water bath, and subsequently wrapping the body in blankets until there is free sweating. If there is evidence of increased renal congestion, as shown by augmented albumin and blood in the urine, dry or wet cups over the renal region will be found most useful in relieving this condition. After these means have been employed, more or less successfully, dry frictions of the skin will be serviceable in increasing renal elimination through the reflex action thus brought about.

In those cases in which errors of diet have been committed, either in connection with, or independently of the effects of cold, we should urge upon our patients the importance of the adoption of a milk diet, for a while at least, and of an effort to use means for the proper oxygenation of this or other aliments. This may be accomplished by breathing pure air and by gentle exercise. Of course it should be understood and emphasized that undue fatigue, emotional excitement, and even slight intercurrent disorders, will be very prejudicial to the well-being of a patient affected with Bright's disease.

Underlying this treatment, as well as all those which have been considered valuable in treating uræmia, there are cardinal principles involved. These are, first, to subtract the poison—get rid of it, carry it out of the system; second, to neutralize it so far as possible. In order to carry out the first indication, we recur to the use of diuretics, or those drugs which increase the bulk of urine, and with it the amount of solid constituents eliminated. Among selected medicaments, potash salts are frequently employed, and no doubt at times with obvious benefit. Nevertheless, in view of acquired knowledge in regard to the poisonous effects of potash salts when taken into the body in the form of food in those who suffer from uræmia, we should be very careful in limiting the amount of these salts when taken as medicine. One of the favorite diuretic infusions is that of digitalis, yet to its employment there are distinct and important objections. Frequently, in these cases, the kidneys are almost, if not quite, impermeable. This impermeability may be due to one cause or a combination of causes. There may be a clogging up of the renal tubules; but there may also be a spasmodic vascular condition, or a passive congestion of the renal vessels. Digitalis, from its action on peripheral vessels, tends to increase this contraction or hyperæmia rather than to diminish it. Inasmuch, therefore, as very little of the drug can be eliminated through the kidneys, it is not infrequent to note the effects of its accumulation in the system, as shown by nausea and vomiting, repeated at times in a distressing and threatening manner. If these phenomena are correctly interpreted, and the dose of digitalis is diminished or temporarily given up, the patient will at times be relieved of the unpleasant symptoms referred to. If, on the contrary, the symptoms be regarded as uræmic, and digitalis be continued in the same or augmented doses, the morbid symptoms, instead of being favorably modified, or disappearing altogether, will continue and become worse. Of course the symptoms may be of a mixed origin. We may have the union of what pertains to uræmia, on the one hand, and digitalis intolerance, on the other. Under these circumstances, it is also rational to stop the use of the drug.

In those cases in which a weak heart is an important, not to say, a primary factor in causing uræmia, it is not amiss to give digitalis. In some of these patients, indeed, I have known it surely to effect very good results.

In regard to the vicarious ways of relieving the kidneys through the increased action of the skin and the intestinal tract, a few words may here be properly added.

Diaphoresis, as well as active purgation, remove a considerable amount of water from the body. They also abstract from the economy what is poisonous. In affirming this fact, however, I must modify it by saying that they remove relatively small amounts of poisonous excreta. These amounts, when compared with the effect of blood-letting, are about nine-tenths less. Besides, it must be remembered that if water be removed from the blood by these methods of treatment, a smaller quantity by so much will be able to pass through the kidneys, and these emunctories of poisonous excreta, of such primary importance, will not recover their normal fuctions so rapidly, or indeed so perfectly.

In addition to the foregoing means of treatment, and as one of undoubted great importance, and against which, I believe, no forcible objections can be urged, I would uphold the use of water by high enemata; as a rule, they should be given moderately cold. These enemata have been used quite a number of years by well-known practitioners with a view to causing the contraction of renal vessels through the reflex stimulation of the abdominal nervous centres. Besides, they act by increasing vascular tension through absorption of the water and filling the vessels. Thus diuresis is promoted. I am also convinced that they are directly of benefit in diluting the poisonous matters contained in the blood and thus diminishing the morbid symptoms due to these substances when present in a concentrated form. Certainly there can be no question about the absorption of the fluid employed in very considerable amount. Whatever portion is rejected by the bowels, no doubt brings away much of the fermentative products of the ingesta, which are un-

[1] Read at the meeting of the Practitioners' Society, February 2, 1894.

questionably more or less continued and added sources of toxæmia, in many instances. I have made use of such injections from these standpoints with the happiest effects in one instance (Case I.). In this example the patient was in such a depressed condition of lowered vitality that I thought it wiser to employ the water warm, rather than cold—the precise temperature being slightly above blood-heat. To the water was added about one per cent. salt, and high injections were given several times daily with a douche bag and a medium-size, long, soft catheter of red rubber attached to the nozzle of the douche bag. The patient lay in the dorsal decubitus during the time the injection was given. There was little or no question in regard to the benefit received from these injections: the pulse improved, the heart action was strengthened, increased flow of urine took place, vitality was evidently increased and the entire aspect and behavior of the patient was rendered more encouraging. The case was one in which, following upon typhoid fever,[1] the gastro-intestinal mucous membrane became affected, apparently with a low type of catarrhal inflammation, and symptoms of nausea and vomiting and non-assimilation of food were very threatening. These symptoms were connected with, and probably in part caused by, inadequacy of renal excretion under the dependence of slight or moderate renal changes.

Whenever the uræmic phenomena are at all menacing and other indicated therapeutic means have failed to relieve, in very many instances it is judicious practice to recur to venesection (Cases II. and III.), or blood-letting by means of cups (Case III.) or leeches. Sometimes coma or convulsions will disappear while the abstraction of blood takes place. In strong, robust patients there can be little doubt that blood letting in considerable quantity, up to twelve or twenty ounces, may be safely and advantageously employed. In other cases of delicate women or young persons blood-letting must not be too abundant on account of its possible weakening influence. Formerly, blood letting, as we all know, was used a great deal more in these cases than it is to day, and it is certain that it was frequently abused. Yet, it is clear that clinical evidence and scientific research justify and support its use, and go to prove that many lives are directly saved by this means, which would otherwise be inevitably sacrificed.

I have seen several patients suffering from uræmic phenomena of threatening nature, in whom all other rational means had been employed without avail, evidently greatly benefited by abstraction of a notable quantity of blood. In one instance, after the venesection I made use of saline transfusion, with at least temporary good effect (Case IV.). In another case, in which my house physician performed the operation of saline infusion, a temporary good result was also obtained (Case V.). In both these cases a fatal result followed, mainly because the renal changes were very far advanced and practically incurable. I am convinced, however, from close observation of these two cases of saline transfusion following abundant loss of blood by venesection, and from one other observed by me in which previously to transfusion there was no considerable loss of blood by venesection (Case VI.),[2] that the operation of transfusion in the treatment of uræmia may be at times very useful in tiding over an imminent period, and perhaps, in enabling the patient to recover, when without the operation he would surely die.

Numerous facts have been observed during the past few years and are reported in current literature, which establish on a firm basis the good effects which may occasionally be expected from this procedure. In certain cases, in which for one reason or another neither the high saline enemata, nor blood-letting, nor saline venous transfusion by itself or following venesection, are employed, we may have recourse to hypodermic injections of warm sterilized salt water, at about the same temperature and containing the same amount of salt that we should employ if we make intravenous transfusion.

In one instance that came under my observation, the hypodermic use of the saline solution apparently caused a considerable degree of pain (Case VII.). It is stated, however, by those who have made frequent use of them, that they are, as a rule, free from this objection. There is no doubt in my mind that even when a patient is in *extremis*, and the heart beats very weak, and the pulse a mere flicker, that these warm salt solutions may be taken up by the vessels of the subcutaneous layer in a remarkable manner. I was witness of this effect on one occasion when I resorted to the injection, more, indeed, to see what degree of palliation could be accomplished in this way than with the idea that any permanent curative effect could be produced. Death followed very soon after the injection, and yet at the post mortem examination, which was made within a few hours after the decease, the subcutaneous tissue when cut into at the site of the injection did not reveal the presence of any fluid. The amount of water injected was about half a pint (Case I.). It is probable that in conditions which are obviously uræmic and which come at the end of acute and exhausting diseases, that the hypodermic injections to which I have referred have a real value which should not be ignored. I would merely instance in this connection the remarkable and encouraging experiences which Professor Cantani, of Naples, has had with these injections, and with his method of high tannin injections in the bowels (enteroclysis) during the late epidemic of cholera in Europe, to show in what other important direction these procedures are available and useful. At times, and even in the presence of symptoms of acute uræmia, the methods described, for different reasons, may not appear the best, or the only ones to employ. The anæsthetic effect of chloroform may be confidently resorted to, and we are all aware that chloroform will at times shorten very manifestly a convulsive seizure. Chloroform is often, in my judgment, a very suitable and proper remedy to thoroughly test, previous to blood-letting, for the reason that we obtain in this way temporary relief, at least from tonic and clonic contractions, which will enable us to bleed our patient more accurately and successfully. West states, in this connection, that we can determine after anæsthesia from chloroform, and when the patient is comatose, how much blood we should take, always being guided by the strength and character of the pulse.

In certain instances, it would seem as if the hypnotic and quieting effects of chloral by the mouth or by rectal injections were especially called for; some cases of convulsions, followed or preceded by delirium, may be thus advantageously treated. In my judgment, in almost all cases in which we properly dread the injurious effects of the opiates, and especially of morphine, and yet feel as if they might be useful, chloral may often be very properly substituted for them. In moderate doses it is one of the few active drugs possessing marked hypnotic calmative properties, which are tolerated well, as a rule, by uræmic patients.

Opiates, as I believe, are of evident value only in rare cases. The reasons for this statement have been given by me elsewhere.[1]

Much has been said for and against the use of pilocarpine as an agent which is at once speedy and effective in arresting uræmic convulsions. On account of the readiness with which it can be employed hypodermically, and in view of its diaphoretic action on the skin, its favorable acceptance can be easily appreciated. In one instance, which I can now recall with great vividness, I am confident that this active principle was the direct cause of profuse salivation, which, taken with an œdema of the lungs, also occasioned by it, hastened, rather than retarded the fatal termination, primarily due to renal changes. It is

[1] At the autopsy it was shown that the case was one of ulcerative enteritis.

[2] Operation by Dr. Hollis, at that time house physician in St. Luke's Hospital.

[1] Vide Transactions of Society of American Physicians, 1893.

also true that at times even a small or moderate dose of pilocarpine will occasion symptoms of heart failure which require immediate stimulation by means of brandy and ammonia to overcome. No doubt the danger from profuse salivation and œdema of lungs should be dreaded in cases in which the skin and subcutaneous tissue are infiltrated with serum, and in which our power to re-establish the function of the kidneys is very imperfect. On the other hand, it would seem as if pilocarpine were a drug that could occasionally be usefully employed. This affirmation is true in cases in which pilocarpine in ordinary doses produces profuse diaphoresis without causing cardiac depression, and without causing excessive action of the salivary glands, or of the glands of the mucous membranes of the bronchi.

While chloroform, chloral, the bromides, and pilocarpine may at times control, in a measure, and visibly shorten the severity and duration of different nervous phenomena connected with, or dependent upon, a uræmic state, none of them meets satisfactorily the underlying pathological causative conditions. For this reason, we must keep in view the fact that it is essential that a diet composed mainly of milk should be adhered to, at least during the acute manifestations of uræmia. It must be insisted upon for many different reasons, among which we shall enumerate a few of the most prominent: Milk by its action lessens the flow of bile, is readily assimilated, does not produce fermentative changes, as a rule, in the digestive tract, forms a small amount of residue from which injurious poisons may be taken into the circulation, contains no injurious potash salts. Doubtless the action of the milk may be aided at times by the moderate use of the neutral salts which carry out of the intestinal canal any injurious substances which are prone to remain there. Further, according to Bouchard, the bile pigment itself, which is according to him the special poisonous element of the bile, may be decolorized and thereby rendered innocuous to the system by the rational use of charcoal given by the mouth. Care in alimentation, above other things, should be emphasized, and although at times, boiled meat, eggs, and cheese may be usefully added to the dietary, as well as other aliments according to the nature of the case and the idiosyncrasy of the individual, yet such variations of diet must be limited and rigidly scrutinized.

Finally, intestinal antisepsis is one of the most important indications to be carried out actively. Naphthaline, benzo- or beta naphthol, salicylate of bismuth, sub-gallate of bismuth, are all useful remedies in lessening the amount of intestinal fermentation, which is a powerful factor in the continuance of many cases in which uræmic manifestations are not infrequent in a mild or chronic form

I have thus given the outline of a general treatment of uræmia, which seems to me rational. Of course certain special symptoms may and do require means of relief. If, for example, there be very marked dyspnœa and this dyspnœa be connected with notable congestion of the lungs, counter-irritation by means of frequent applications of dry cups or warm mustard poultices will give very evident relief on many occasions. In connection with this marked infiltration of the pulmonary structure, if the quantity of urine be notably diminished, or almost suppressed, it is plainly indicated to make use of active purgation, despite the objections already urged by me against its inconsiderate or too frequent employment. If the toxic phenomena shown be rapidity and oppression of breathing, but with no evident local phenomena clearly present, we frequently have reason to be grateful for the magical relief afforded by the nitrites, nitro-glycerine, or nitrite of amyl by inhalation (Case VIII.). In similar instances, there can be little doubt that oxygen—if pure and diluted with a proper proportion of nitrogen—may be inhaled frequently, or almost continuously, with very great relief to a patient's suffering and menacing condition. Not all such cases are thus relieved, any more than all cases of toxic dyspnœa are relieved by nitro-glycerine even in frequent and considerable doses. But this is merely an admission of the fact, alas! too often true, that the organic changes of the kidneys are such that life may be more or less prolonged, but the fatal termination must inevitably occur, and that too, very soon.

Delirium is best managed with chloral and the bromides. Gastric phenomena of nausea and recurrent vomiting with lime water, vichy, brandy, kirsch, creosote, iodine, etc.

At times, a collapsed and almost moribund patient may require hypodermic stimulation with extract of coca,[1] strychnine, or ether.

The following letters, which were sent to me by Dr. Charles Thorndike Parker, one of the attending surgeons to the Chambers Street Hospital, appear to me of considerable interest. It affords me great pleasure to state, in this connection, that I am personally indebted to Dr. Parker for demonstrating to me, several years ago, the efficacy of intravenous saline infusion. At that time Dr. Parker was house surgeon to St. Luke's Hospital.

"46 East Thirty-fourth Street, February 2, 1894.

"Dear Dr. Robinson: Enclosed is a report from the House Surgeon of Chambers Street Hospital. As we do not keep any records of these cases it is hard to get at the facts. All I can say is that we use this method on all subjects in uræmic coma and have found it answers better than any other. In cases where they are very plethoric we draw off blood from the other arm while infusing, but when anæmic we simply infuse.

"All our results are not as good as the three mentioned in Dr. Brinsmaid's letter, although they have all shown marked improvement very quickly.

"Very truly yours,

"Charles T. Parker."

"Chambers Street Hospital, 160 Chambers Street, February 1, 1894.

"Dear Dr. Parker: In answer to your request for the history of the cases of uræmia treated by saline infusion, I am sorry to say that they have all been Reception Ward cases, and that, therefore, no complete histories were kept.

"To my knowledge, three cases have been treated by this method, all showing very nearly the same effect. The last of these cases was brought in in a state of complete coma, sensations entirely absent, even in the conjunctiva. Hot-air baths were given and produced no effect, not even starting up any perspiration; his median basilar vein was opened and about one quart of blood allowed to escape, during this time double that amount of saline infusion was injected into the same vein on opposite side; in about five minutes he showed signs of returning consciousness, and at the end of fifteen minutes was in a profuse perspiration, and was able to sit up and give his name and address, sensation having completely returned. He had no other attack while under observation, and was discharged at end of twenty-four hours, and walked out seeming perfectly well. The other cases have shown almost similar results, although recovering more slowly; they were all under forty years of age. One was not plethoric and, therefore, was simply infused and no blood taken from him. I am sorry to give you such an incomplete history, but, as you know, these cases do not go to the wards, and, therefore, no elaborate data are kept.

"I am, very respectfully yours,

"W. B. Brinsmaid."

Case I. *Ulcerative Enteritis and Nephritis—Uræmic Convulsions Treated and Cured with Saline Solution: Enemata—Rapid Absorption of Subcutaneous Injection of Salt Solution Immediately Before Death—Gavage Successful when other Methods of Feeding Failed.*[2]—Michael

[1] The solution I recommend is made according to the following formula: To four ounces fluid extract coca, add one ounce glycerine, heat upon water-bath until all alcohol has been driven off, then add sufficient water to make product measure two fluid ounces.

[2] I am indebted to the courtesy of Dr. Martin, my house physician, for the history of this case.

S——, aged seventeen, single, native of Germany, was admitted to St. Luke's Hospital, September 14, 1892. Family history was negative. The patient states that he has never been ill before the present sickness, which began two weeks ago, with headache, feverishness, and loss of appetite. These symptoms continued, and three days ago the patient felt prostration enough to confine him to bed, and also began to suffer from a slight diarrhœa.

On admission patient complained chiefly of prostration and malaise. His pulse was 106; respiration was 30 to the minute, and temperature by rectum 102⅘° F. The urine was acid, specific gravity 1.020, there was a trace of albumin, sugar was absent, Ehrlich reaction was obtained as far as color is concerned, microscopic examination revealed hyaline casts.

The physical examination by the house physician was negative, excepting slight tenderness and gurgling in right iliac region. Spleen was not felt. The patient was fairly well nourished. There were a few spots, resembling the eruption of typhoid, on the abdomen. Tongue was furred in the centre. The case was supposed to be one of typhoid fever, and the patient was treated on the Brand plan. A tub-bath, the temperature of the water being 65° F., was given whenever the temperature was above 103° F. The patient bore the bathing well, and the tubs were followed by marked fall of temperature, once dropping from 103⅘° to 98° F. The temperature continued most of the time above 103° for seven days, after that it began gradually to subside and in four days had reached normal temperature.

The patient began at this time to complain of extreme abdominal tenderness, and his urine at the same time was acid, specific gravity 1.012, albumin was present to the extent of fifteen per cent. by volume, microscopic examination showed red blood-cells and casts.

The patient a few days later began to vomit, this vomiting continued day after day for several weeks, several times the vomitus contained blood. The vomiting at no time was very severe, but since it was uncontrolled by various expedients, nutrient enemata were resorted to. The patient had by this time become extremely emaciated, and an hemorrhagic eruption had made its appearance about ankles, wrists, elbows, and anterior-superior spines of ilium. The urine at this time, October 11th, contained forty per cent. by volume of albumin, casts, and some red blood-cells. Patient was passing from thirty-two to forty ounces of urine on that day and several previous days.

October 12th.—The patient had five convulsions in the course of several hours. The convulsions were general, there was some tension of radial pulse during the seizures. The patient was given a hot bath, glonoin, and chloral, during and immediately after the convulsions.

The next day, two high enemata of, water, two pints; salt, two drachms, at 100° F., were given. These injections were given with the idea of diluting the poison which, circulating in the blood, caused the convulsions; about thirteen ounces were usually retained. The amount introduced into the bowel was afterward reduced to one pint: of this about ten ounces were retained.

The patient had no convulsions after the rectal injections were begun; whether this was due to the water thus absorbed or to chloral, glonoin, etc., which were given with the idea of diminishing arterial tension, is uncertain.

October 16th.—The patient began to complain of rectal pain after enemata: also passed blood from bowel, and vomited greenish fluid several times. Nutrient enemata were now stopped. Gavage was now resorted to with beneficial results. The patient was given by stomach-tube, four times daily, one egg well-beaten; peptonized milk, four ounces; whiskey, one-half ounce. This nourishment was retained, the hemorrhagic spots became less, the tongue became more moist.

October 20th.—Patient objected to passage of stomach-tube, and the attempt to forcibly pass it exhausted him so much that feeding by this method was stopped. Warm saline injections were also stopped. The patient from this time on began to fail. He daily became more emaciated and feeble, the hemorrhagic spots increased in number. The eruption in places was vesicular, the vesicles containing blood. From time to time greenish fluid and blood were vomited; there were frequent small passages of blood from the bowel. The temperature was subnormal most of the time, once being 96° F. The pulse was rapid, and at times very feeble. The patient was stimulated with champagne and whiskey, and oxygen inhalations were frequently given, but no benefit was derived therefrom.

October 29th.—It was evident the patient was sinking rapidly. At 8 A.M., temperature was 101° F., respirations 40, and pulse 136. At 11 A.M. pulse was almost imperceptible, the breathing rapid and shallow. At 11.36 A.M. 100 c.c. of salt solution were slowly injected beneath the skin. The patient died quietly, twenty minutes later.[1]

Autopsy showed very abundant, irregular ulcerations in lower five or six feet of ileum, leaving in parts only scattered islands of mucous membrane. Peyer's patches less affected than the rest. Other organs normal, excepting slight opacity of cortex of right kidney. There was no evidence of salt solution in cellular tissue in which it was injected, thus showing that it was absorbed.

Diagnosis. Ulcerative enteritis and nephritis.

The interesting points in the case were: That there were no more convulsions after saline solution enemata; that when other methods of feeding failed, gavage was successful, and that 100 c.c. of salt solution were rapidly taken up immediately before death.

CASE II. *Profuse Epistaxis in Case of Chronic Endocarditis and Tubercular Arthritis of Knee—Beneficial Effect of Injection into Rectum of Two Pints of Warm Transfusion Fluid—Transfusion Fluid all apparently Absorbed.*[2]—Caroline L——, aged eighteen, admitted November 27, 1893, suffering from tubercular arthritis of knee, and chronic endocarditis. Examination of heart: marked thrill over apex, presystolic and systolic murmur; heart enlarged.

On January 28th patient had a severe epistaxis. Hemorrhage lasted about twelve hours, posterior nares were then plugged, thus stopping hemorrhage. Patient was weak; pulse, poor force; complained of "air hunger." These symptoms continued, and on January 29th two pints of warm transfusion fluid (sodium carbonate, fifteen grains, sodium chloride, one and one-half drachms, aqua, two pints) were slowly injected into rectum. The injection was given in two parts, one-half hour intervening. Transfusion fluid all retained, and apparently absorbed. Patient's condition was much improved, pulse better force, and this was shown in sphygmographic tracings.

CASE III. *Uræmia—Phlebotomy on Two Occasions—Chronic Diffuse Nephritis—Uræmia cured; Nephritis Improved.*—Peter B——, aged forty-three, married; Ireland; brass finisher. Family history negative. Last winter patient began to have swelling and stiffness of lower extremities. The swelling has been more marked during the last seven weeks. During this time the water has been diminished in amount: has had severe dyspnœa and palpitation. The dyspnœa was so severe that patient had to sit up in bed and was unable to sleep. Has lost considerable flesh and strength, abdomen began to swell three weeks ago, and since last Monday the hands have been swollen. During the last week, patient has been vomiting. Has used moderate amount of liquor, and has taken it before breakfast. On admission, appetite poor, bowels constipated. Urine acid, 1 017; no albumin, no sugar; microscope: hyaline casts, epithelium.

January 15th.—Heart apex, sixth space in mammal line. Thrill conveyed to finger at tip of ensiform carti-

[1] From October 14th until death patient passed from twenty-eight ounces of urine down to ten ounces at end of life.

[2] This case is reported merely to show the beneficial effect of saline solution enemata after abundant hemorrhage.

lage. Over apex there is a systolic murmur, transmitted into axilla; over pulmonary area there is a double murmur, systolic and diastolic, heard over second and third spaces at left of sternum; at tip of ensiform cartilage there is a pre-systolic murmur; there is epigastric pulsation; no murmur heard in back. There is venous pulsation on both sides of the neck, increased on pressure over the liver. Systolic murmur heard in vessels of neck, can be heard in brachial artery near bend of elbow. Lungs: Over lower hand-breadth of both chests, behind, there is flatness and diminished voice sounds; superficial crepitation heard over left base. Liver extends two finger breadths below free border of ribs in right mammal line. Spleen negative; abdomen negative; no ascites. Inguinal glands easily felt. Very slight œdema of lower extremities. Enlargement of scrotum on right side; considerable œdema of skin.

Fluid extract of digitalis, one minim every four hours. Milk diet. Tincture of chloride of iron, ten minims; glycerine, one drachm; spirits chloroform, ten minims t.i.d.

Double murmur scarcely heard over aortic space, both heard slightly along left border of sternum, especially that accompanying the first sound. There is considerable enlargement of the heart, dilatation of both cavities, considerable dilatation of veins. There is an aortic direct and regurgitant murmur, the direct being more prominent, and a mitral regurgitant murmur. No marked irregularity of pulse.

January 17th.—Urine alkaline, 1.023. No albumin. No triple and amorphous phosphate ammonium-urates.

January 22d.—At about 10.30 A.M. yesterday, patient tried to get out of bed, did not recognize his wife, and was very restless. At 1.30 P.M. patient had a convulsion, uræmic in character. At 2 P.M. another, and another at 2.45, when he was put in a hot-air bath. In the interval between the convulsions was very restless, and had to be tied down. While in the bath was given pilocarpin, one-fifth grain, hypodermically. At 4 P.M. had another convulsion. Venesection was performed on right arm, and seven ounces of blood withdrawn. Was quiet during the night. During the convulsions the pupils were widely dilated. This A.M. are moderately contracted. There is hyper resonance of voice at right apex posteriorly beneath right clavicle; prolonged expiration and increased voice. Omit medicines to-day.

R. Glonoin, $\frac{1}{100}$ grain, every hour, fifteen doses daily. Only passed two ounces of urine up to 5 P.M.

January 25th.—Urine acid. Albumin, trace; no uric acid. Spermatozoa leucocytes.

January 26th.—At 7.15 P.M yesterday patient had a uræmic convulsion, pupils were dilated, but was not followed by coma. Seven ounces of blood were withdrawn from median basilic vein by house physician, the left side. At 7.45 had another convulsion, followed by coma, and patient was conscious at about 8 15. At 1.15 A.M. patient had another slight convulsion. Urine, acid; 1.011: albumin, trace; microscope: hyaline and granular casts.

January 28th.—Tincture of chloride of iron, 10 minims; glycerine, one drachm, t.i.d. after meals.

January 31st.—Urine alkaline, 1.016; albumin, one per cent.; microscope negative.

February 9th.—Mitral regurgitant murmur heard over apex. Heart action quiet.

February 19th.—Allow farinaceous diet.

February 26th.—Urine acid, 1.013; no albumin; microscope: spermatozoa; leucocytes.

March 16th.—Heart apex fifth space just outside mammary line, no murmurs.

Discharged. Uræmia cured. Nephritis improved.

URINE RECORD.

CASE IV. *Chronic Nephritis and Chronic Endocarditis—Acute Pulmonary Œdema—Notably Relieved by Venesection to the Amount of Thirty Ounces.*—Edward Dunne, aged thirty, Ireland, single, stableman. Family history, negative.

Personal history: Scarlatina when young. Gonorrhœa once, five years ago. No rheumatic or malarial history. Marked alcoholic habit since seventeen years of age; for past seven weeks has left off whiskey and taken to malt liquors, but not heavily. Otherwise history negative, and patient has always been in good health up to time of present trouble.

Present trouble commenced seven weeks ago with slight cough and some dyspnœa, both of which were much and suddenly increased after a trip of thirty miles on horseback leading another horse, which gave considerable trouble, requiring unusual strain. At one time since raised some blood on coughing, but not much. Cough has become better during past three weeks, and also dyspnœa for past week is much better. Feet and legs swelled shortly after his trip on horseback; swelling disappears somewhat on lying down.

On admission complains chiefly of cough and dyspnœa. Appetite good, bowels regular. Pulse, 102; respiration, 28; temperature, 103⅕° F.; urine, 1.017, four per cent. albumin; no sugar; leucocytes, red blood cells, granular and blood casts. Diet, milk.

Cardiac impulse very diffused, dulness from one inch to right of sternum to base, nipple line from second space to seventh costal cartilage, moderate epigastric impulse, slight apical thrill, maximum intensity of first sound, sixth space, one and one half inch outside parasternal line; action regular, rapid, and forcible. Over apex is a loud, rasping murmur, which runs sharply up to sound of mitral closure (presystolic?). There is a faint double murmur over aortic area. From left nipple to middle of sternum, and second space to sixth rib, is a superficial respiratory friction crepitus. Lungs: Impaired resonance beneath right clavicle; many sonorous and sibilant râles over whole chest; dulness at both bases $\frac{1}{6}$ with numerous fine, moist râles posteriorly. Liver: Dulness sixth rib to second below costal arch; edge cannot be distinctly felt. Splenic dulness to free border of ribs, edge thought to be felt. Dulness in both flanks. Abdomen not distended, thought to contain a little fluid. Lower extremities, well marked œdema, several old cicatrices, and large area of pigmentation on legs. Pulse, 136, regular, quite forcible; increased tension. Nutrition good; no cyanosis.

Ice-bag to precordium 5.30 P.M. Fluid extract digitalis, two minims every four hours. Glonoin, $\frac{1}{100}$ grain every two hours. Codeine, $\frac{1}{2}$ grain, every four hours.

At 8.30 P.M. dyspnœa became suddenly marked; rapidly increasing œdema of lungs; pulse full and rapid;

considerable cyanosis. Oxygen ordered; anterior and posterior chests dry cupped. Eighteen ounces of blood taken from right forearm, and twelve ounces from left, giving great relief, between 9 and 10 P.M. Strophanthus, five minims hypodermically at 10 P.M. Mustard poultices, 1 to 5, followed cupping of chest. The oxygen seemed to cause patient more difficulty in breathing than relief. At 12 P.M. there was some return of œdema of lungs, confined to upper chest. Strychnine, $\frac{1}{60}$ grain, and atropine, $\frac{1}{100}$ grain, hypodermically, at once and to be repeated in two hours. Strychnine then to continue by mouth, alternating with glonoin, $\frac{1}{100}$ grain, every two hours, all other medicine being stopped until morning rounds. At 2 A.M. patient was sleeping quietly.

November 10th.—On morning rounds strychnine was continued, held at $\frac{1}{100}$ grain. Digitalis stopped, and hypodermic of $\frac{1}{100}$ grain atropine given and chest ordered to be cupped and followed by mustard poultices, 1 to 5. Patient has been quiet and comfortable all day, sleeping a good deal. He stated that the attack of last night was similar to his original attack after having ridden the thirty miles, only considerably worse, not treated at time, better next morning.

Heart action regular; good force, 124; apical murmur distinctly presystolic; still a few subcrepitant râles here and there over both chests, 10.40 A.M. Urine neutral, 1.017; albumin, four per cent.; red cells and casts.

November 11th.—Make glonoin $\frac{1}{60}$ grain. Very comfortable night. Urine, albumin, one per cent; 1.017; red cells and casts.

November 12th.—Stop mustard poultices. Very comfortable all day.

November 13th.—Stop codeine. Carbonate of iron, 1 drachm, t.i.d. Maximum intensity of first sound in fifth space just within nipple line. Auriculo-systolic murmur rather soft in quality. Marked accentuation of pulmonic sound. Lungs negative.

November 14th.—Small amount of light diet; much improved.

November 15th.—Make strychnine sulphate $\frac{1}{60}$ grain every four hours. Urine alkaline, 1.011; small amount of albumin; no casts; no blood.

November 16th.—Maltine and peptone, one-half ounce, t.i.d.

November 17th.—Patient improving daily; appetite good. Cascara, 10 minims, t.i.d.

November 18th.—Allow up. Make glonoin every four hours.

November 19th.—Urine alkaline, 1.016; albumin, small amount, no sugar, no casts.

November 21st.—Murmur still softer. Heart action quite regular and conservative.

November 22d.—Weight, 122 pounds.

November 25th.—Make glonoin $\frac{1}{100}$ grain. Make strychnine, t.i.d.

November 26th.—Allow clothes.

November 29th.—Urine negative. Weight, 127 pounds.

December 5th.—Stop cascara. Bowels regular. Omit glonoin and strychnine for twenty-four hours. Has been complaining of dizziness. Some cough. Compound licorice mixture, one drachm every four hours.

December 6th.—Weight, 131 pounds. Some pain in right chest on taking long breath. Iodine applied.

December 9th.—Blister to right chest.

December 10th.—Relieved by blister.

December 12th.—No more chest pain. Maximum intensity nearly $\frac{1}{6}$ in nipple line; action regular; murmur distinct; somewhat softer than formerly; few pleuritic friction sounds over base of right lung. Pulse, 104; regular, good force.

December 13th.—Make glonoin $\frac{1}{60}$ grain.

December 14th.—Sitting up daily and doing well.

December 16th.—Urine acid, 1.022; faint trace of albumin; no sugar; no casts.

December 17th.—Right chest painted with iodine.

December 21st.—Still complains of pain over right chest. Iodine no good. Cauterized.

December 27th.—Weight, 134 pounds.

December 29th.—Patient up and about ward; doing well. No more pain in chest for some days back.

January 3d.—Weight, 135 pounds. Condition good. A little weak. Heart doing well now, but murmurs still present.

I. Nephritis improved; II. Œdema cured.

Case V.—*Œdema of Lungs Causing Intense Dyspnœa, and Doubtless Due to Uræmia, Greatly Relieved by Wet Cups, Caffein, and Jalap Powder when other Treatment Failed to Relieve.*[1]—Eliza T——, aged fifty, born in Ireland, single, seamstress by occupation, admitted to hospital November 20, 1893.

Family history negative. Patient enjoyed good health until sixteen days before admission. At that time she began to be short of breath and to notice swelling of feet and abdomen. These symptoms continued increasing in severity up to the time of admission to hospital.

Physical examination of patient at that time showed heart a little enlarged, and the second sound accentuated. There was a slight effusion into each pleural cavity, over both lungs a few subcrepitant râles could be heard. Pulse was 104, tense; patient looked anæmic.

Examination of urine showed specific gravity of 1.018, a trace of albumin, hyaline and granular casts.

Patient was kept in bed, on milk diet. Glonoin, $\frac{1}{100}$ grain, was administered every two hours. The next day patient became decidedly worse; pulse more tense, breathing labored, and signs of slight œdema of lungs became marked. Only seven ounces of urine were passed in the twenty four hours. Glonoin was given, $\frac{1}{100}$ grain every hour; chest cupped; patient a little relieved by treatment.

For the next few days patient continued about the same, severe dyspnœa almost constant, except when temporarily relieved by inhalation of espic cigarettes, or by cupping. Urine varied from sixteen to twenty-four ounces in the twenty-four hours. Hot-air baths were given daily.

On November 25th dyspnœa became more severe, signs of œdema of lungs rapidly appeared. Both chests were cupped, a drachm of compound jalap powder was given as a purge. Wet cups were applied over kidneys. Caffeine citrate in one grain doses was administered every hour.

The patient under this treatment improved, breathing became easier, quantity of urine in next twenty-four hours increased to thirty-four ounces. Pulse became less tense. Examination of urine at this time showed specific gravity 1.020; twenty-five per cent. by volume of albumin, numerous hyaline and granular casts.

From this time on patient improved, dyspnœa disappeared, swelling of feet became less. Albumin in urine gradually diminished, quantity of urine increased.

January 13, 1894.—Patient discharged from hospital greatly improved. The case then was evidently one of chronic nephritis, during an exacerbation. The prominent feature was the dyspnœa, evidently dependent on the contraction of the arteries, and the feeble heart action, and relief therefore by the caffein—a heart stimulant, and glonoin—an arterial dilator. The wet cups over the kidneys seemed to markedly lessen the congestion of those organs, as the quantity of urine was increased and the patient's condition accordingly improved.

Case VI. *Chronic Nephritis—Repeated Uræmic Convulsions—Temporary Benefit from Blood letting and Saline Infusion—Death.*—M. B——, aged seventy-eight, single, entered St. Luke's Hospital October 18, 1889. Perfectly well until two months ago when patient was taken with a heavy cold; then noticed swelling of the feet. During last three weeks this has increased, involving legs, hands, and face. Frequent micturition, especially at night. Moderate prostration for one week.

On October 16th had six convulsions, which were pre-

[1] Notes of cases taken by Dr. Martin, of the House Staff.

ceded by ocular disturbances. Convulsions said by family physician to be uræmic in character.

Urine alkaline, ninety per cent. albumin (by precipitation); no glucose; microscope showed red, white, and epithelial cells; few granular casts. Patient well nourished and very anæmic. Heart apex in fourth space about four and one-fourth inches from median line. Impulse forcible; no murmurs; accentuated pulmonic sound. Pulse, 104; small, some increase of tension.

Treatment.—Sulphate of magnesia two drachms every two hours; cups to kidneys, hot-air baths, milk diet.

October 19th.—Glonoin, $\frac{1}{100}$ grain, every two hours.

October 21st.—Acetate of ammonia and iron mixture, one-half ounce, t i.d.

Between this date and December 17th frequent urinary examinations were made. Specific gravity remained between 1.012 and 1.018. Urine always acid when examined. Grammes of albumin to litre varied from five to sixteen. Urine was usually loaded with casts, mostly fatty, also hyaline and granular; bowels kept freely open. Frequent hot-air baths.

December 21st.—Urine decreasing; œdema increasing; considerable tension of radial pulse. Infusion of digitalis (cold), one half ounce every four hours.

December 30th.—General convulsion at 7.30 A.M., repeated several times during day. Croton oil, one minim, on tongue; hot-air baths; chloroform for convulsions; entirely unconscious. 5 P.M.—Convulsions continue; wet cups over kidneys; venesection to eight ounces, followed by saline infusion to a similar amount.

December 31st.—No more convulsions since venesection, etc. Temperature, 105° to 106° F. Coma complete; some rigidity of right upper extremity; one or two loose alvine dejections. Radial pulse almost imperceptible at wrist; 170 to 180. P.M.—Face flushed; surface body moist; breathing, cog-wheel in character; hypostatic congestion; left pupil more dilated.

January 1, 1890.—Patient died about 9.45 A.M. No autopsy.

Case VII. *Chronic Diffuse Nephritis—Uræmia—Infusion with Salt Solution—Temporary Improvement—Death.*—William C——, aged twenty-nine; male; Bohemia; cigarmaker. Family history negative.

Patient never has had rheumatism, scarlet or intermittent fevers; uses alcohol moderately; no distinct history of specific infection; had diphtheria three months ago; since July has had occasional chill followed by heat and sweating, last chill occurred last Sunday, these chills occured irregularly; has had shortness of breath and some obstruction in nose for the past week; since July urine has been high colored; swelling of feet; puffiness under the eyes in the morning; dimness of vision; vomiting, and a great deal of headache; has had diarrhœa for the past two days.

On admission patient is well nourished; appetite poor; tongue coated; pulse, 100; respiration, 38; temperature, 96° F. at 8 A.M. Urine, 1.010, acid; albumin, twenty-three per cent., no glucose; microscope: epithelial casts, granular matter, kidney epithelial. Heart: apex fifth space just outside nipple line; impulse heaving; cardiac sounds exaggerated; no murmurs. Lungs: anteriorly, numerous fine and coarse moist râles on cough; posteriorly, râles much less numerous than anteriorly. Liver negative. Spleen negative. Abdomen, some sensitiveness on pressure in epigastric region; inguinal glands easily felt on both sides. Extremities: slight œdema of lower extremities; right tibia is much enlarged, bows forward, and over its anterior surface are two large cicatrices surrounded by bluish-black areas evidently of long standing. Chloride of ammonia mixture one drachm every four hours. Milk diet.

October 30th.—Allow farinaceous diet.

November 1st.—Allow acid drink, Hosford's, one drachm to one pint.

November 2d.—Stopped chloride of ammonia mixture. Tincture of gentian, three minims, t.i.d. Glonoin, $\frac{1}{100}$ grain, every two hours.

November 3d.—Partial obliteration of right labio-nasal fold. No deviation of tongue.

November 4th.—Patient has passed no urine since yesterday P.M. Cups ordered over kidneys, followed by a digitalis poultice. Hot air bath to be given this P.M. Compound jalap powder, one drachm, immediately. Salol, ten grains, every six hours. P.M.: Stop salol. Naphthaline, fifteen grains every four hours. Stop peptonoids. Peptonized milk; infusion digitalis, two drachms, t.i.d.

November 5th.—Urine, 1.012, acid; albumin, thirty per cent.: no glucose: urea, four grains to one ounce; microscope: granular, epithelial casts, blood casts, red blood cells, some uric acid crystals.

November 6th.—Patient yesterday, at about 3 P.M., had a convulsion; was freely stimulated. Infusion with salt solution.[1] Patient rallied, but only temporarily, and died at 6.40 P.M. No autopsy.

Case VIII. *Chronic Diffuse Nephritis—Transfusion of 650 c.c. of Salt Solution, followed by Temporary Amelioration of Symptoms.*—Julia H——, aged twenty-two; domestic, married. Admitted to hospital, October 15, 1891. Family history negative.

Personal history: Five years ago had an attack of dropsy, recovered in three months, had a miscarriage some months ago. Has not been unwell for last three months, but does not know the exact date of last menstrual period.

Present illness began suddenly two weeks ago at night, with nausea and vomiting, which recurred all night: the next morning at five she began to have fits, her friends told her they lasted for two days; that she had spasms and bit her tongue; till three days afterward she was unconscious. When she came to herself she had a dreadful headache, which has persisted more or less intensely ever since. Till three days ago says she often saw lightning.

Has had complete anorexia, no more nausea or vomiting. She has passed a small amount of water since her illness began and has noticed general swelling of body. Her bowels have been constipated. Temperature, 99° F.; pulse, 100; respiration, 24.

Examination by house physician negative, excepting slight flattening of left side of face, and slight weakness of left arm and leg. Urine was acid; specific gravity, 1.007; a trace of albumin was found; no sugar present. Microscopic examination showed pus and epithelium; amount passed in twenty-four hours was forty-eight ounces.

Patient was put on milk diet. Medication consisted of potassium citrate, ten grains t.i.d. Reynolds's mixture, 2 drachms, afterward.

October 18th.—There was marked arterial tension and glonoin, $\frac{1}{100}$ grain, was given every hour. Urinary examination was negative. Amount passed in twenty-four hours was twenty-two ounces. For the next ten days patient continued to have high arterial tension; she also vomited from time to time, and was troubled with persistent and severe headache. Urinary examination showed that forty per cent. of albumin was present in urine, and considerable blood. Specific gravity, 1.012, and few granular casts. Amount of urine passed, thirty-four ounces. A few days later patient began to suffer from dyspnœa.

October 31st.—In the afternoon pulse became much slower and very irregular; dyspnœa was much more severe. Anterior chest was cupped, and two ounces of whiskey were given every four hours. Patient was very restless, thrashing about in bed from 4 P.M. to 8 P.M.

[1] In this case, although no mention is made of the fact, a considerable amount of blood was probably taken from the patient previous to transfusion.

Temperature rose to 101° F.; respiration, 40; pulse, 112.

At 8.30 P.M., 650 c.c. of salt solution at 100° F. was infused into right median cephalic vein, operation well stood, followed by period of quietness, slower respiration and more regular pulse. (This improvement probably due to infusion.)

For the next three or four days patient continued about the same; vomiting, however, was more persistent, and nutrient enemata were resorted to.

November 4th.—Enemata were stopped. Oxygen was given twice daily, and caffeine, two grains, every two hours. She was restless and noisy all day; respirations slow and shallow; pulse under 80, fairly regular. No urine passed. Toward night she grew worse; breathing became very bad.

November 5th.—At 12.25 there was slight twitching of face and hands, head extended, no real convulsions. Respiration gasping in character, but pulse was of good force, tension rather great. At 1.30 A.M. she died quietly but suddenly. No autopsy.

The case was evidently one of chronic diffuse nephritis, the point of interest being the apparent relief given by the infusion of 650 c.c. of salt solution into a vein, but the beneficial effects seemed to be of very short duration.

CASE IX.—I am indebted for the history of the following case to the courtesy of Dr. Charles T. Parker. It is one of albuminuria accompanying uræmic convulsions. The treatment was venesection, followed by saline transfusion. Rapid recovery took place. The history reads as follows: On a call for the Chambers Street Hospital Ambulance, August 27, 1891, it was sent to the City Hall Park, where a man was found lying on a bench unconscious. Patient was removed to the reception ward, his urine examined and found to be loaded with albumin. Before reaching the hospital it is said that he had a uræmic convulsion. Once there, every effort was made to arouse him, but in vain. Ten minutes after admission to the ward patient had a typical uræmic convulsion in which his face became cyanotic. The pupils were equally dilated and their reaction lost; the pulse was of high tension; the respiration intermittent and tonic spasm of the chest muscles occurred. The temperature was slightly raised above normal and the reflexes were lost. The convulsion began with a tonic contraction of the muscles. The mouth was tightly closed, the patient's head extended, the trunk slightly curved backward. The extremities became stiff and rigid and the fingers were clinched. This tonic stage of the convulsion lasted about fifty-five seconds and the clonic stage immediatety followed, in which the facial muscles were drawn so as to exhibit violent contortions. The eyeballs rolled from side to side, and the muscles of the upper and lower extremities underwent clonic spasms. The tendon reflexes were completely lost. Subsequently the patient seemed to be at ease for a time, and during this period he suddenly raised his head voluntarily more than once.

Infusion was advised and performed. Patients' arms were washed with green soap and water and afterward rubbed with ether. Venesection was then made and two pounds of blood were allowed to escape from the vein at the elbow. Immediately after the bleeding two quarts of freshly made salt solution were injected in the vein at the same spot. This injection seemed to work like a charm. No sooner was it terminated than the patient's limbs began to move, his face appeared normal, his breathing was greatly improved, and the reflexes returned. Twenty minutes after the transfusion patient was able to speak clearly about himself and remembered that he went to the Park and fell over on the bench.

Wound healed rapidly and patient was discharged cured in five days.

CASE X. *Typhoid Fever with Uræmic Phenomena, Treated by means of Hypodermic Saline Solution—No Apparent Benefit—Death.*—John M——, aged twenty-two, born in New York, admitted October 25, 1892, with symptoms of typhoid fever. Disease ran a rather severe course. Patient on the fifteenth day of his illness became much worse. Delirium of a low muttering character was present most of the time; mouth dry; pulse irregular. Urine, alkaline, 1.008; albumin, four per cent. Microscope showed blood-cells.

Symptoms of this character continued, and on November 4th, 75 c.c. of warm saline solution were slowly injected subcutaneously in gluteal region; fairly good absorption, but injection accompanied by great pain. Infusion was given with the idea of diluting toxic substances in blood which were causing the severe constitutional symptoms. The patient was not benefited by injection, he became steadily worse and died on November 6th. There was no autopsy.

CASE XI. *Chronic Nephritis showing Notable Temporary Effect of Inhalation of Nitrite of Amyl in diminishing Tension of Pulse.*—In this case $\frac{1}{75}$ grain of nitroglycerine had been given every hour for fifteen consecutive hours without obvious influence on tension of pulse. It was stopped because it caused intense throbbing sensations in the head.[1]

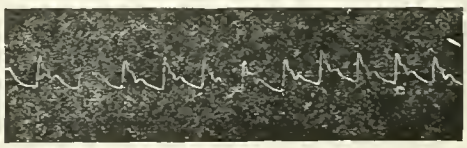

FIG. 1.—Mary H——. Tracing taken from right radial. Pulse rather small and hard. Artery is thickened. Percussion stroke (lines of ascent) line slightly slanting.

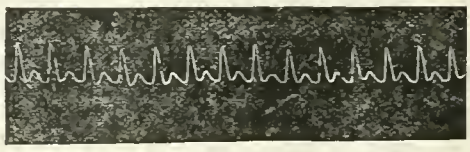

FIG. 2.—During inhalation of ♏ iv. amyl nitrite. Tension is now absent. Arterial coats relaxed and pulse dicrotic. Although the muscular fibres are relaxed the artery is still felt thickened, showing arterio-sclerosis. Line of ascent vertical.

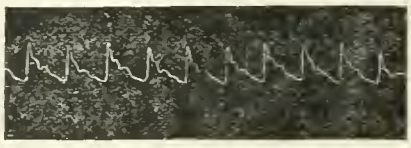

FIG. 3.—Tracing ten minutes after amyl nitrite, showed pulse practically returned to previous condition.

Mary H——, aged twenty nine. Severe headaches, nausea and occasional vomiting, prostration. Urine acid, 1.017; albumin, twenty per cent; no sugar; hyaline casts and red cells. Passes 50 ounces daily. Is getting daily hot-air baths, occasional doses of morphine and is allowed light diet.

NOTE.—During inhalation (just before second tracing) patient's face flushed and became slightly cyanotic; pulse became more rapid than in second tracing, pupils dilated, and extensors of limbs were tonically contracted. For about one minute patient was partially unconscious. This condition lasted two or three minutes and was followed by profuse sweat.

Lactophenin.—Landowsky (*Sem. Méd.*, February 7th) has tried the effect in several cases of lactophenin, a substance very closely allied chemically to phenacetin. This drug has anti-neuralgic properties analogous to antipyrin, and has, besides, a genuine hypnotic effect. The amount given daily was from sixty centigrammes to three grammes, divided into several doses. The only disagreeable by effects caused by the drug seemed to be diaphoresis and slight giddiness in a few of the patients.

[1] Notes and tracings were given me by Dr. Thomas, of the house staff at St. Luke's Hospital.

THE SELECTION AND PHYSICAL EXAMINATION OF THE RECRUIT.

By CHARLES B. EWING, M.D.,

CAPTAIN AND ASSISTANT SURGEON, UNITED STATES ARMY.

All men offering for military service are included in the general term "Recruit." By "recruiting" is meant "the operation by which men who compose an army are raised."

Definite rules and regulations for the selection of the soldier in our service were not formulated till 1840, when Assistant Surgeon Thomas Henderson published his "Hints on the Medical Examination of Recruits for the Army," etc. This continued to be the authoritative work till 1856, when it was republished with additional matter by Assistant Surgeon R. H. Coolidge. In 1858 Surgeon Charles S. Tripler published his first volume, in which he took the "Aide-Mémoire de l'Officier de Santé" for the French army as the basis of his work on "Recruiting and Inspection of Recruits." Though this was republished in 1866, the death of the author prevented the completion of the second part. In 1863 Assistant Surgeon Bartholow compiled a manual founded upon statistics issued by the Provost-Marshal General's Bureau. This work, though printed thirty years ago, contains much valuable information and is well worth perusal by all examining surgeons. The books of Assistant Surgeons Tripler and Bartholow were the official guides till 1884, when Colonel Greenleaf, Deputy Surgeon-General, wrote an epitome of Tripler's Manual, which underwent revision by the same author in 1890 and 1893, much new information, with some modifications of the old, appearing.

Recruiting in our service is conducted by the Adjutant-General, under the direction of the Secretary of War. It is both general and special. General when performed by officers selected and detached for such duty in the various cities where rendezvous are established. Special when confined to the department, regiment, or particular military organization. Field officers are detailed to superintend the service and command the depots, which are three in number, two for infantry and artillery, and one for cavalry. I find, upon perusal of the regulations of 1839, that the general organization of the recruiting service of to day does not differ materially from that of the former period.

After the recruit has submitted two recommendations as to character, which have been verified by the recruiting officer, he is examined. If found fit he is sworn in as soon as practicable, within six days after his examination, uniformed, and sent to the depot of the arm of the service which he is to enter, when, after remaining three months, he joins his regiment.

The physical examination of the recruit is conducted by the medical officer in the presence of the recruiting officer. This duty falls upon the recruiting officer when there is no medical officer present; in which case the medical inspection is made, within two days after the arrival at the depot or post, by the surgeon in charge.

Paragraph 925, A. R., says that "the physical examination of recruits will be conducted in accordance with Greenleaf's 'Epitome of Tripler's Manual for the Examination of Recruits.'" Colonel Greenleaf's Manual, having passed through three revisions, is a most excellent one. His task has been particularly difficult, because it governs the examining surgeon and likewise the recruiting officer, in the absence of a medical officer. The result is, that when recruits are passed as fit at the rendezvous, then found disqualified at the depot by a Board of Inspectors convened in such cases, it becomes very unpleasant for both concerned, and particularly the medical officer, upon whom the onus usually falls. While the Boards of Inspectors at depots closely scrutinize the acts of the recruiting officer, he escapes much criticism, by reason of his not being a medical man, that falls to the lot of the examining surgeon. The surgeon, therefore, has a dual rôle, the first being to obtain the very best men and pass only those who are fit, and the second, to please the recruiting officer, who usually wants a larger number enlisted. As it resolves itself into a question of quantity at the expense of quality, the experienced examiner will decide in favor of the smaller number physically fit.

I shall consider briefly our regulations governing the selection of the soldier (recruiting), and point out, according to my experience, where I think they should be modified, following with some suggestions looking to an improvement in our present methods.

Vision.—Particular attention should be given by the examining surgeon to this part of his duty. A large number of rejections at the present time are due to defective vision, though no particular care is taken to determine its character except in special cases. It is interesting to note the developmental phases of this branch of our work. The only one of these mentioned by Tripler, in his edition of 1858, is myopia, which he says "is an objection to a recruit," and repeats this in the edition of 1866. No mention is made of hypermetropia or astigmatism. Presbyopia is spoken of in both editions, but is not disqualifying, "unless decided."

The above was changed in G. O. 82, A. G. O., Washington, D. C., August 13, 1879, when very important and comprehensive instructions were given in lieu of the paragraphs I have quoted in Tripler. Accompanying these was a pamphlet containing a very clear and complete description of the optical appliances enumerated in the Order. This, taken altogether, was the most important regulation ever issued to the medical department of the army on vision, being both practical and sensible.

None of the anomalies in the refraction of the eye were disqualifying unless accompanied by disease which impaired vision to such a degree as to prevent the counting of the test-spots. These test-spots were "black" and circular, four tenths of an inch in diameter, placed on cards, and were to be counted at twenty feet. This being equal to seeing, at six hundred yards' distance, a black centre or bull's-eye three feet in diameter, on a white ground.

Besides the pack of test cards the following were furnished: A simple optometer with spectacle glasses and test-types, and a set of test-wools for detection of color-blindness.

The regulation just mentioned lasted eight years, when changed by circular dated Surgeon General's Office, Washington, June 7, 1887. This did away with the test-cards, types, and circular spots, substituting the Snellen types of twenty feet, and modified materially the whole question of vision in the recruit.

Myopia and astigmatism are absolutely disqualifying, and hypermetropia, "except when moderate and free from disease." Amblyopia, amaurosis (dim vision), and presbyopia are not thought worth mentioning.

We quote the circular, which is as follows:

"This examination requires the greatest care and patience on the part of the recruiting officer; it is made with cards bearing the 20-feet test-types and test-characters. To use the cards measure off a distance of twenty feet in a straight line; place the applicant with his back to the light at one end of the line, while the examiner stands at the other and holds the card exhibiting the test types or characters in full view of the applicant, and so that a good light falls on the card. Each eye should be examined separately, one being covered with a card (not with the hand) by an assistant, who, standing behind the applicant, directs him to read the types on the card held by the examiner. If he cannot read, the card bearing the characters is presented to him, which he is directed to describe. The types should be read first from left to right and then from right to left; the characters should be described as to the number of arms seen on each and the direction in which they are pointed, whether upward or downward, to the right or left. If the applicant should be unable to read the

test-types or describe the test characters correctly with either eye, he must be rejected."

It is only necessary to establish simply the defect according to this.

The inference drawn that *every* eye is perfectly emmetropic, to say the least, is fallacious. It does not state how the refractive defects—myopia, hypermetropia, and astigmatism—are to be determined by using simply the Snellen 20-feet type and characters. The optometer and prisoptometer are not mentioned.

The army which approaches our own the closest in its method of recruiting is the English, who have only to do with voluntary enlistments. The cost of putting a recruit into the army, due to their residence in all parts of the world, is greater than that of any other country. Here vision is tested with the much-abused "test-dots," or miniature bull's eyes, Snellen types, the ophthalmoscope, and optometer. The quality of eyesight is determined by Snellen's optotypes; if, however, these can only be read short of the normal distance some defect exists, and the ophthalmoscope and optometric apparatus are brought into use; particularly where the recruit is unable to read are the test dots substituted for Snellen's.

The English regulation is to the effect that myopia, hypermetropia, and astigmatism are only disqualifying when accompanied with vision inferior to one-fourth Snellen. This is qualified by Longmore in the paragraph headed "Quality of Vision for a Marksman at Full Rifle Range," where he says "vision in the right or aiming eye should be normal, and this can only exist when the eye is emmetropic, or as nearly so as not to exceed 0.5 D, or one-eightieth inch of ametropia and when the accommodation is normal; at the same time the left, or eye not employed in taking aim, ought not to possess less than three fourths of the normal standard of visual acuteness."

I have carefully scrutinized the regulations governing vision as it relates to recruiting in foreign armies, but as "conscription" is in force in the majority of them defective vision does not exempt from military service, for if found unfit in one branch the recruit is utilized in another, so that only very extreme errors of refraction act as a bar.

From my experience as an examining officer, I am of the opinion that the test-cards and characters supplied are entirely inadequate to the proper determination of vision, and that many applicants are rejected who would otherwise be accepted. To obviate this I think the regulations governing vision should be modified. It is quite apparent that the dots are better objects with which to test vision, especially where the applicant cannot read, than rectangular objects, as the question at issue is, after all, whether or not the recruit can become a marksman. Therefore I suggest:

1. That our nomenclature as it relates to vision be revised.

2. That other diseases which are disqualifying, besides those of refraction, be added to our present list.

3. That the test-dots or miniature bull's-eyes be used, but that they be changed to conform to the elliptical bull's-eye of the target now in use in the army, and that, as the present bull's-eye of the 600-yard target is 18 × 24 inches in its vertical and transverse diameters, the test-dot should conform to this, to be seen at 4 5 m. or 15 feet; both would subtend the same visual angle. The eye is supposed to occupy the apex of a triangle, of which the diameter of a circle seen at any given distance forms the base; then, if the distance of the circle be increased or diminished, its diameter must increase or diminish in the same ratio, if the angle at the apex of the triangle is to remain unchanged. In similar triangles the bases are to each other as the altitudes. Therefore the diameter of a circle which at 4.5 m. or 15 feet distance shall be equivalent to a circle 24 inches (vertical diameter of bull's-eye) in diameter at 600 yards (1,800 feet) is found by the following proportions:

1,800 feet : 15 feet : : 24 inches : 1-5th of an inch.
1,800 feet : 15 feet : : 18 inches : 3-20ths of an inch.

Hence the size of the ellipse seen at 15 feet would be 1-5th x 3-20ths of an inch in diameter.

If we desire 20 feet as the distance at which the elliptical dots should be seen, then the following proportions would obtain:

1,800 feet : 20 feet : : 24 inches : 4-15ths of an inch.
1,800 feet : 20 feet : : 18 inches : 1-5th of an inch.

Thus at 20 feet the size of the ellipse would be 4-15ths × 1-5th of an inch in diameter.

A greater number of these dots should be placed upon one large card instead of upon numerous small ones, as heretofore. Thus the test would be more exact and the applicant would be unable to obtain knowledge of groups of dots as he could upon the small cards formerly in use.

4. That where defect is discovered, its quality be determined, also that the prisoptometer be furnished all recruiting rendezvous, so that recruiting officers, in the absence of the examining surgeon, might be able to find quality of refractive error of vision. This instrument is very simple in construction, and recruiting officers should have little difficulty in using it. Of course this would only apply to determination of simple and not compound refractive errors.

5. That the present degrees of disqualification, especially as they relate to anomalies of refraction, be modified as follows:

a. Myopia.—When the elliptical test-dots cannot be counted at 4.5 m., and where myopia is found to be greater than 1-20th in right eye and less than 3 4ths vision in left.

b. Hypermetropia.—Where the test dots cannot be counted at 4.5 m. by right eye and less than 3 4ths vision in the left. The disabling effects of hypermetropia are more or less felt in both far and near vision, and increase with age at certain ranges.

c. Astigmatism.—Where myopic or hypermetropic ametropia exists with vision inferior to 1-4th.

Amblyopia not being a refractive defect, and not corrected by glasses, should disqualify unless the 1-5th × 3-20th inch test dots be counted at 4.5 m.

Amaurosis, an affection of the retina, for a like reason should disqualify.

Pterygium only when it impinges on the cornea should disqualify.

6. The room in which vision is tested should be well lighted and at least 20 feet square.

Hearing.—This is such an important requirement to the recruit for entrance into our service that a few words will not be out of place.

The "Epitome of Tripler's Manual," edition 1884, under the caption "The Ears," says that "Deafness of either ear constitutes an absolute cause of rejection. The applicant should be placed about twelve feet from, and with his back toward, the recruiting officer, and be required to repeat certain words, addressed to him in a low tone of voice; his failure to respond will speedily show this defect."

This was modified by circular dated Headquarters ot the Army, A. G. O., Washington, June 7, 1887, as follows:

"Strike out paragraphs following 'Deafness of either ear constitutes an absolute cause of rejection,' and substitute:

"As the distance at which the natural tone of voice may be heard in a closed room, when both ears are normal, is about fifty feet, the distance at which the applicant is to stand from the examiner must be as great as the apartments will allow, not to exceed fifty feet. The applicant will stand with his back to the examiner, who is to address him in a natural tone of voice. When the distance is less than forty feet, it should be specified on the examination form, and the tone of voice will be lowered. Failure of the applicant to respond to the address of the examiner will demonstrate a defect.

"The personal attention of the recruiting officer or sergeant must be given to closing the entrance to each ear separately, by pressing with the thumb the small lobe

(tragus) situated in front of the opening to the inner ear.

"Advantage should be taken of the absence of other sounds to make the examination. Recruiting officers should remember that a man may be totally deaf in one ear, and yet may hear all ordinary conversation perfectly if the sound ear is not completely stopped. Deafness of one ear is a bar to enlistment, but in ordinary occupations it might not be observed."

The present governing manual of 1893, a revision of former epitomes, orders, and circulars, contains all the above with this addition:

"All men enlisted for the artillery arm of the service at a military post, or assigned to that arm from a depot, shall, before such enlistment or assignment, besides undergoing the ordinary examination, be examined specially with a view to establishing the fact of the patency of the Eustachian tubes and the integrity of the tympanic membranes, in default of which the men are unfit for that arm. In time of war deafness of one ear is not cause for rejection. It should be borne in mind that defects in hearing are easily feigned; therefore, when they are alleged by conscripts, the examination should be made by a medical officer. Genuine deafness cannot be concealed."

It does not require very careful perusal of what I have just read to conclude that our methods of testing hearing should be more exact. The rooms in which recruits are usually examined at rendezvouses, vary in size, being rarely over twenty and never fifty feet in anyone dimension. Again, it is very difficult to so modify the "natural tone of voice," as to give any specific value to it when heard at less distance than the maximum stated. Further, the test of hearing as determined by the voice is not a fair one; hence I suggest the apparatus of Galton, which is most excellent for the exact determination of hearing.

It consists of an india-rubber tube which communicates through five others with five fixed whistles of small bore, and at depths that will give 50, 40, 30, 20, and 10 thousand air-vibrations in a second, respectively—that is, of the several depths of 0.067, 0.084, 0.113, 0.169, and 0 380 inch. Each tube is nipped by a separate clamp. These are numbered in order, 5, 4, 3, 2, 1, and serve as keys. When anyone of them is depressed, air is blown through the corresponding whistle, and is thrown into vibrations that can be heard by some as a shrill and pure note, while others hear merely a puff or nothing at all. Every person has his limits of power of hearing high notes, quite independently of the general acuteness of his hearing. The test lies in ascertaining which is the shrillest of the five notes that is audible. The precise limit of audible sound may be found by using a whistle that has a movable plug for its base.

Age.—At present, in our service, no particular importance is attached to age and its "physical equivalents" in relation to height, weight, and vital (chest) capacity. Much attention has been paid to the relative values of height, weight, and chest-girth, considered singly and collectively, but not as connected with age. Definite rules are given for the determination of certain weights where the heights are fixed; likewise specific statements are made showing the relation of chest-girth to height; but one looks in vain for a column of ages to correspond with the physical equivalents mentioned.

In the very earliest days of the Republic, as shown by the Statutes at Large, page 119, vol. i., the limits of age in the army under Washington were from eighteen to forty-six. During the war with France, in 1798, the age was any that the President might direct. By an enactment of Congress, March 16, 1802, the maximum age was reduced from forty six to thirty-five, which obtained till January 11, 1812, when the maximum was again raised and fixed at forty-five. The War of 1812 arose, and as hostilities became more active, demand was made upon Congress for more troops, so that the Act of December 10, 1814, called out all "effective men" between the ages of eighteen and fifty. These limitations were not trenched upon till 1825, when the maximum was again reduced to what it had been twenty-three years before, and became thirty-five. The Mexican War did not change these figures so far as the regular army was concerned, though many volunteers were in the field possessing ages above the maximum stated. During the War of the Rebellion the minimum age was raised to eighteen in the regular army, the maximum still remaining at thirty-five. Under the enrolment act, however, the ages were fixed between twenty and forty. The minimum in our service was again modified April 23, 1874, by War Department circular, so it became sixteen. Our present regulations prescribe the minimum and maximum to be sixteen and thirty-five, respectively; though the age below eighteen is limited to musicians, and between eighteen and twenty-one to those who obtain consent of parents or guardian. By circular dated A. G. O., May 26, 1892, the maximum age was reduced from thirty-five to thirty for original enlistments, no maximum existing, so far as I know, relating to re-enlistments. Some stress is laid by our governing manual upon the fact that for "acceptable colored recruits the age of twenty five or twenty-six is practically the maximum, because after that they are liable to be physically stiffened and mentally dulled."

I should say that about nine-tenths of the original enlistments in our army are between twenty-one and thirty years of age. The limits fixed for entrance to West Point are seventeen to twenty-two.

The consensus of opinion is well put by the lamented Dr. Parkes, of the medical department of the English army, in these terms: "That although a recruit may be usefully trained at an early age, no man under twenty years of age can be regarded as an efficient soldier fit for service." Actual experiences of many competent observers confirm this.

The first Napoleon said, after the battle of Leipsic: "I must have grown men; boys serve only to fill the hospitals and encumber the roadsides." The Duke of Wellington thought old soldiers the "soul and strength" of the army. General Roberts, in his great march from Cabul to Candahar in 1886, found it was the young soldiers who succumbed, while the old became stronger each day. Sir James McGrigor found the soldier under twenty years of age unequal to the "harassing duties of service" during the Peninsular War of 1805 to 1814. Lord Raglan, the commander-in chief in the Crimea, found the recruits sent him "so young and unformed that they fell victims to disease and were swept away like flies" The Duke of Cambridge and Viscount Hardinge give like testimony. The annual report of the Surgeon-General of the Army for 1885 showed such a marked increase of sickness, and "the rate was so much above the mean for the whole army, that he questioned whether the services rendered by these young men are equal to the cost of their maintenance."

Minimum Age.—It seems the general opinion that before a recruit has acquired the physical and moral qualities necessary to enable him to execute the duties incident to military life, he must have attained a certain age. This should not be below eighteen when the training of the recruit is to commence, and under twenty as a soldier in the ranks.

The equipment is of such weight that only the strong, healthy, and robust can carry it and at the same time render service.

Dr. Fallot says: "Conscripts at the age of eighteen have not attained their full growth, and medical men are well aware that the complete development of the human body requires an exemption from great fatigue, abundance of healthy nourishment, undisturbed sleep, and a tranquil mind—a concurrence of circumstances which never occurs in the army."

Coche, in his "De l'Opération Médicale du Recrutement et des Inspections Générales," expresses a similar view, "that recruits at eighteen years of age are commonly unfit for the duties of the army, not only in time of war but in a period of peace." Kirckhoff, who had much

experience with troops in active warfare in the Netherlands, says: "We ought to establish it as a general rule not to receive a recruit into the army below twenty years of age or above twenty five. Under twenty years of age a man has not requisite strength to enable him to undergo the fatigue of military duty, and after twenty five his joints do not possess that flexibility or freedom of motion which is necessary for acquiring the discipline of a soldier." He also lays stress upon the fact that only about five per cent. of the infantry exceed forty years of age, and that at that time they nearly all become unfit for active service. Therefore the period of a man's active service, according to this observer, is from the twentieth to the fortieth year.

The above shows conclusively how wrong it is to expect any long-continued exertion from the average recruit of eighteen or twenty years of age. Again, the constrained position produced by the equipment, and the erect attitude which goes to make up the military air and carriage of the soldier, differ materially from the conditions surrounding the recreative exercises of the civilian. This has been well put by Parkes, who describes the state of the soldier on the march as the position of "attention" put in motion.

It is well to consider the question of metabolism, or tissue change in the body, produced by prolonged exercise as in marching, where weight is to be carried. Maclaren, of Oxford, has given in his work on "Training," as the result of a long pedestrian tour (quite equal to a long march), exceeding nine hours daily, with knapsack of twelve pounds, the following: "The chest fell from 41 to 39½ inches; the upper arm from 14½ to 13⅛ inches; the lower arm remained unchanged at 12½ inches; the lower limbs, on the contrary, were vastly increased, the calf of the leg passing from 16 to 17½ inches, and the thigh from 23½ to 25 inches." This, however, is not near so irksome, and not to be compared to the soldier on the march, who carries in our service an equipment weighing over five times as much (including gun and ammunition), clothed in heavy uniform, girded with straps, and whose pace must be a regulated one, only being allowed to halt at command. The destruction and disintegration of tissue under these conditions are certainly very great, and this is usually attended by "partial embarrassment of the system." It is fair to presume that this embarrassment must increase with the weight to be carried, the labor to be performed; hence a glance at our equipment for the infantryman will be of some interest.

The equipment for field service is as follows:

1. The blanket bag, containing two blankets, one pair trousers, one poncho, one shirt, two pairs stockings, one piece shelter-tent, one pair drawers, one overcoat, one towel, one pair shoes, one piece soap, etc., the whole weighing 34 pounds.

2. The haversack, containing the meat ration can, tin cup, knife and fork, spoon, tin plate, and three days' rations of hard bread, pork, or bacon, and coffee and sugar, weighing 9½ pounds.

3. The canteen, which when filled weighs 5 pounds and 10 ounces.

4. Rifle and bayonet, weight 10 pounds and 2½ ounces.

5. Field belt and bayonet scabbard, weighing 1 pound and 12 ounces.

6. Seventy rounds of ammunition, weighing 7 pounds and 9½ ounces, being in all over 64 pounds, and not including such accessories as pocket knife, money, pipe, tobacco, etc. Of course in time of war this could be reduced, just as in the past. The reduction to forty pounds is possible, but this would necessitate the throwing away of everything except the armament, to which is added one hundred rounds of ammunition and rations for the field to last, say eight days. This equipment is four pounds greater than that carried by the Roman soldier, and twenty one to twenty-two pounds more than that of the "old army" of antebellum days.

(To be continued.)

NEPHRO-LITHIASIS.

By A. H. CORDIER, M.D.,

KANSAS CITY, MO.

CLINICAL LECTURER ON GYNECOLOGY, KANSAS CITY MEDICAL COLLEGE; MEMBER AMERICAN MEDICAL ASSOCIATION; CORRESPONDING MEMBER PHILADELPHIA OBSTETRICAL SOCIETY, ETC.

SINCE Morris, in 1880, placed the operation of nephrolithotomy in the category of modern surgical procedures, many operations of a like character have been successfully performed by surgeons in all countries. These successes have led to an extension of the surgery along the ureter, so that now this narrow tube is invaded from either the bladder or kidney extremity, its canal dilated for stricture, and impacted stones removed from any part of its course. The formation of calculi in the pelvis, calyces, and in the parenchyma of the kidney, certainly is not of rare occurrence, and demands the attention of the general practitioner and surgeon, that their presence may be early recognized and the proper procedure for their removal resorted to promptly. It is the prophylactic or anticipatory surgery that brings the best results, the lowest mortality, the most cures and restored functions. This class of surgery is called rash, mutilating, unjustifiable, etc., by a few of our would-be modern surgeons who are still poulticing tibial sequestra and draining pus-tubes and ovarian abscesses through the groin and vaginal vault.

The great destruction wrought to the kidney structure by an impacted calculus can best be understood by examining the kidney of one of these neglected cases.

Calculi may form in the pelvis or calyces at any age, but is more likely to occur in early childhood or after the fortieth year. Uriate of ammonium in infancy, uric acid in adults, and oxalate and phosphate of lime after forty being the composition of these stones at these ages. They may develop in one or both kidneys, in the pelvic calyx, parenchyma, or all combined, the secreting structure of the organ as a rule being injured in proportion to the size of the stone, duration, and location. A small stone may lead to the complete destruction of the kidney by occluding the ureter for a long period, or, if small enough to pass through this narrow canal, may give rise to no other symptom than severe pain during the passage, and cease to give further trouble, unless by its presence in the bladder it acts as an irritant or as a nucleus for the development of a vesical calculus. Again, a large stone may, by a gradual growth in a location that does not produce an obstruction to the flow of the urine, attain an enormous size without producing much suffering by its presence. The kidney may become one large cavity containing pus, blood, urine, or all combined, without the patient having experienced any of the so-called characteristic paroxysms of nephritic colic. A stone weighing several ounces has been removed, post mortem, from a cyst, the kidney structure having been destroyed. The woman had presented no history of such a state of affairs. This case is a rare one, and is mentioned to call attention to the fact that all these cases do not have a typical history. As a rule, a patient with a suppurating kidney due to the presence of a stone will have hectic fever, emaciation, and pus in the urine. A pyo-nephrosis may insidiously develop in the sac of a hydro nephrosis (due to presence of a stone) without the development of the usual concomitant symptoms of the presence of, or development of, pus. A case may begin as a retention cyst if the stone occludes the pelvis, the calyces, pelvis, and even the parenchyma, being dilated, forming a large tumor perceptible on inspection and palpation, attaining in some cases the size of an adult head. Suppuration, in such a cyst, may take place without any acute exacerbation of pain or fever. An imprisoned stone giving rise to much pain may by an ulcerative process be set free in the cellular tissues surrounding the kidney and develop a perinephritic abscess. Like abscesses in the region of the appendix these post nephritic suppurations are always secondary. The cause, in the majority of instances, will be found originating about the pelvis or the ureter. Many of these cases are incorrectly diagnosed as psoas

and iliac abscesses due to a carious vertebra, and a plaster jacket applied to prevent a scoliosis and produce a cure. These cases will continue to suppurate as long as the sequestrated calculus is permitted to remain in the abscess cavity.

It is remarkable how much urine one of these seemingly disorganized kidneys will secrete where the ureter is patulous, or even through a urinary fistula. A normal quantity, or even more, is often passed from a kidney the microscopical appearance of which would indicate the complete destruction of its secreting structure. Where true albuminuria is present it is due to the tissues of the secreting substance being involved, and not to lesions of the calyces and pelvis. Albumin due to the presence of pus is misleading until its exact source is discovered—not always an easy matter.

In the last three months I have operated for the removal of nephritic calculi on three patients, two being females, one male, the left kidney being affected in one of the women, the right in the other two cases. The male was twenty two years of age; the women thirty-three and forty-four. The largest stone removed weighed two and a half ounces, and was composed of phosphate of lime.

I append the history of two of the cases to illustrate the two types of the disease, the acute obstructive nephro-lithiasis, with perforation and perinephritic abscess, and the chronic partial obstructive, with retention and development of the stone in the calyces and pelvis, with chronic pyo nephrosis.

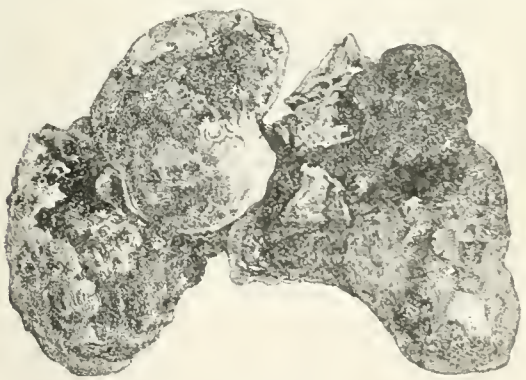
The third case was of the acute variety, with post-nephritic suppuration of nine weeks' duration at the time of the operation.

Case of Nephro-lithiasis—Operation—Recovery.—C. W——, aged twenty two years; single. This young man, while in perfect health, was taken with a pain of the most intense character in the region of the right kidney. This pain persisted with unabated severity for a number of hours. Large and oft-repeated hypodermics of morphine finally subdued the greater intensity of his suffering, but while not under the influence of the opium he suffered much. Three or four days after the beginning of his attack he developed a fever of a septic type, his pains at the same time greatly subsiding. It was at this period of his illness that the pain-producing, impact-calculus found an exit through the walls of the ureter or pelvis, at the same time relieving his pain by its escape, and producing evidences of sepsis and local suppuration.

In the beginning of his attack he passed blood-stained urine, the quantity being much diminished. After the imprisoned calculus was set free in the tissues surrounding the kidney, an enormous quantity of urine (polyuria) was passed, the specific gravity of which was only 1.002. This (polyuria) increased flow of pale urine with a low specific gravity has been a diagnostic symptom in several of my cases of acute nephro-lithiasis.

The young man continued having his irregular chills, sweats, and fever for four weeks, losing much (eighty pounds) weight, and all his strength. During this period he was passing large quantities of pale, light urine, and was having more or less pain in the region of the right kidney. At this time I saw him for the first time.

After analyzing his symptoms and history I decided that I had to deal with a perinephritic abscess of a nephritic calculous origin. An operation revealed the correctness of my diagnosis. The young man made an ideal recovery, and is, to day, a perfect picture of good health.



This case had been diagnosed appendicitis, typhoid fever, abscess of the liver, and malaria, by as many physicians as I have enumerated diseases. This mistake is easily made in similar cases if the physician is not systematic in his diagnostic methods.

Case of Nephro-lithiasis—Nephro-lithotomy—Stone Weighing Over Two Ounces Removed.—Mrs. P——, of Olathe, Kans., patient of Dr. C. G. McKinley. This lady, aged forty-four, mother of four children, youngest five years old, was sent to me by Dr. McKinley.

About five years ago she noticed a small enlargement in the region of the right kidney. At the same time more or less pain and uneasiness in that locality was felt. The uneasiness has continued up to this time. At no time has she had hard or unbearable pain like that due to the passage of a renal calculus. The tumor has continued to grow, but in the last year much faster than formerly. She is fairly well nourished, but some sallowness of the skin is noticed. Has at no time been confined to her bed from any symptoms pointing to this locality as a cause of her illness. Has had no fever at any time, or local tenderness, pointing to any acute suppurative process. Has been doing the ordinary duties of a housewife. Her urine during the last year has been clouded. On examination I found it contained much pus. Her bladder has been irrigated frequently with boracic acid, etc., with no diminution of the pus in the urine. Her bladder has not, at any time, been acutely inflamed or painful.

She has not at any time had any acute exacerbations of pain like that produced by the passage of a renal calculus. At times she has passed large quantities of urine, but it was always clouded, during the last year. On examining her I found a tumor the size of an infant's head in the right renal region, slightly movable, rather soft or semifluctuating, painless on handling, and smooth to the touch; dulness in front of the growth, but below the head of the colon resonance was elicited on percussion. The ascending colon was pushed to the inner side of the growth. Taking the history and well-marked physical signs I decided that I had to deal with a pyo nephrosis, the origin of which was, very probably, due to the presence of a calculus. The tubercular origin of the condition was eliminated by its duration, pain, absence of bacilli, disease of other kidney being eliminated, and absence of rapid and continuous emaciation, so often seen in the tuberculous kidney.

Operation performed November 18, 1893, Dr. J. D. Griffith assisting. An incision from the anterior or free end of the twelfth rib (which was short), was made, extending downward and forward, in a circular direction, to near the anterior superior spine of the ileum. This

was carried in to the anterior border of the quadratus lumborum. A few cutaneous branches from the lumbar and intercostal arteries were divided. The outer edge of the latissimus dorsi and posterior border of the external oblique were exposed and divided, then the internal oblique and transversalis. The edge of the erector spinæ was not disturbed; this brought me down to the outer border of the quadratus lumborum. Much of the dissecting was performed by the fingers and handle of the scalpel. The kidney was now pushed from in front into the incision as much as possible. An exploring trocar was introduced, to make sure that I was not entering the peritoneum, and to find pus or other suspected fluids, and to hunt for stones. The first thrust of the trocar struck both pus and calculi. This opening was enlarged with the forceps and fingers. I found a large collection of pus in the kidney, and stones, the aggregate weight of which was about three ounces. These were removed, the largest one weighing over two ounces and a half. (See cut.) Cavity was irrigated and packed with gauze, and

drainage put in. A large part of the incision was left open, as these cases suppurate freely and for a long time. The hemorrhage was at no time very alarming, being mostly venous from the parenchyma. A few hours after the operation she passed blood-stained urine, showing that the ureter was patulous, as was evinced by the passage of pus in the urine before the operation. Two days later her urine was quite normal in appearance and quantity. The dressings were more or less soiled with pus of a urinous odor.

"Ideal surgery" would have demanded the removal of the kidney at the same time I removed the stone, but the mortality of the primary operation of nephrectomy for a suppurating kidney is very nigh. If it is necessary the diseased organ can be removed at a later period, and that, too, with a better prospect of recovery from the operation.

ERGOT IN THE TREATMENT OF PERIODICAL NEURALGIAS.[1]

By W. H. THOMSON, M.D.,

PROFESSOR OF MATERIA MEDICA AND DISEASES OF THE NERVOUS SYSTEM, UNIVERSITY MEDICAL COLLEGE, NEW YORK.

Having for a number of years relied upon ergot in the treatment of migraine, I was led to try it also in cases of neuralgias which were marked by the feature of periodicity, with results of which the following reports are illustrations:

Case I.—My friend Dr. T——, a practising physician of this city, furnishes me with these notes of his own case. He writes: "During the winter of 1883–84 I was troubled with frequent headaches. The attacks grew more and more frequent until they assumed a periodical character, coming on daily about 6 P.M. This condition increased, until, in the early spring of 1884, they became intolerable and necessitated my staying in bed. Under the impression that the trouble was malarial I had taken quinine and arsenic, together with bromides, without relief. When I took to my bed I took thirty grains of quinine daily for three days, in doses of fifteen grains night and morning, combined with capsicum; also fifteen grains of bromide of potassium every two hours. During these three days I also took two twenty-grain doses of chloral. All this was attended with no relief, the pain beginning with an occipito-cervical aching and then increasing until the whole head was affected. On the evening of the third day you called and prescribed one drachm doses of fluid extract of ergot, to be repeated every two hours until relieved. Your prescription was:

℞. Extract. ergotæ fluid.,
Elixir cinchonæ.....āā ʒj.
M. Sig: Two teaspoonfuls in water every two hours, unless pain was relieved, when the intervals might be lengthened.

You stated at the time that it was a mistake to take large doses of quinine for periodical neuralgias, and directed me in the future to take but ten grains a day at 4 P.M. In an hour after taking the first dose of your prescription I went to sleep, which was the first sleep I had had in three days, and this ergot treatment made my recovery rapid. I must add that my headache was attended with no chill or rise of temperature. Several times since 1884 I have been threatened with similar attacks, but have always been immediately relieved by your ergot treatment."

Case II.—Mr. B—— I saw in consultation with Dr. A. E. Carpenter, of Boonton, N. J., who sends me the following account: "Mr. B——'s was a case of remarkably severe periodical neuralgia, following a mild attack of la grippe. It affected the intercostals and also the great sciatic of the left side. The attacks came on about 10 P.M. every night, and were almost entirely uncontrollable. I had prescribed large doses of quinine and of other antiperiodics, without any satisfactory results. I even anticipated the attacks upon two occasions with half a grain of morphia hypodermically, but the same dose was required again before midnight. After becoming thoroughly alarmed about him, as you know, I invited you to see the case with me. It was the day after the patient had had the worst night of all. You ordered full doses of ergot in connection with moderate doses of quinine. That night the patient did not suffer at all, and had the best night which he had passed for a week. I continued your treatment for five days, and the patient made a speedy and permanent recovery. I found no necessity to give him any more morphia after beginning the ergot. The case had been of ten days' duration prior to your visit, and each succeeding night its severity was progressive."

Case III.—Mr. W——, a German druggist, living in Greenport, L. I., came, September 4, 1893, with a story of persistent daily headaches, lasting all day, but subsiding at night, beginning at the occiput and extending anteriorly. They first came on in the summer of 1892 and lasted through the autumn, but left him in the winter. In June, 1893, they returned worse than ever, and continued to date. Ever since they began in 1892 he became much constipated, though he was never so before, and his constipation continued through the winter, when he was free from headaches. He had faithfully tried quinine and Warburg's tincture in very free doses without any relief. Pulse at his first visit, 110. Ordered to try four grains of exalgine at a dose, and if this did not relieve him, then to take a drachm of ext. ergot. fl. with elix. cinchonæ. On September 11th he reported that the exalgine gave him no relief, but the ergot, though it nauseated him, relieved him at once. He took the ergot from September 4th to September 8th, after which he has had no return of the headaches.

Case IV.—I saw in consultation with Dr. L. Feigenblatt, of this city, Mr. W——, a young gentleman much given to horseback riding. Began to suffer from headaches, beginning at the occiput and then extending to the temples, which came on about 11 A.M. daily and gradually grew worse till they reached their acme about 4 P.M., after which they subsided in the night, without, however, entirely disappearing. Dr. Feigenblatt failed to check their progressive severity till, on their becoming intolerable, he tried on one day thirty-grain doses of chloral with thirty of potassium bromide every two hours for two doses, with little more effect than causing a slight drowsiness. The next day, the patient becoming maniacal from pain, sixty-five grains of chloral, sixty of bromide, and thirty of antipyrin were given within two hours. This dosing caused a profuse sweating and moderate sleep. The third day a consultant who was called in recommended that quinine and Warburg's tincture, which had been tried at the beginning of his treatment by Dr. Feigenblatt, should be resumed in large doses. Accordingly sixty grains of quinine and two ounces of Warburg were administered in twenty-four hours, with even worse afternoon paroxysms of pain than before. The next day the bromide, antipyrin, and chloral doses were resumed, as the patient had got some sleep from them, but as no permanent relief from the recurrence of the attacks was expected, I was asked to see him, which I did at 1.30 P.M., October 21, 1893. I found him in bed with a pulse of 106, eyes suffused, and with some photophobia. Temperature, 99° F. Complained of considerable dull occipital headache and very apprehensive that it would soon come on in paroxysms. He had never complained of stiffness of the neck, or of aching in the spine or limbs; his only other complaint was that he had been troubled for a number of weeks with a morning cough, for which he had consulted the above-mentioned gentleman, who had seen him with his family physician for his headaches; but his cough persisted till his headaches came on, when it left him. Physical examination of his chest by me was with negative result. I advised his physician to begin at once with drachm doses of ext. ergot. fl. every hour, for three doses, with ten grains of quinine with the first two doses; and that if his stomach rejected either of the doses, that the ergot be given per rectum. I then requested the doctor to send me a report of the result.

[1] Read before the New York Neurological Society, January 2, 1894.

A week afterward the doctor wrote to me that with the first dose the patient experienced a good deal of relief; that he vomited the second dose, whereupon it was given by enema; and this was soon followed by complete subsidence of the headache, with profuse perspiration. This medication was repeated for three successive days, with final cure of the headaches, and what was also curious was that the second ten-grain dose of quinine, when given with the ergot, produced decided symptoms of cinchonism, whereas when it had been given singly in much larger doses before, it had failed to do so.

The severity of the pain in some cases of periodical neuralgias is remarkable. In one instance a gentleman, aged sixty-five, the type of a sturdy, self-reliant business man, became so overcome by a frontal neuralgia, with extreme photophobia and lachrymation, which came on about 10 A.M., that he could not help crying out from it like a child. In most instances, however, such neuralgias are of a dull, aching character, but frequently accompanied with great restlessness or marked depression. Thus a married lady once sent for me on account of what she described as an intolerable heavy aching coming on late every afternoon, in the lower part of the back, with aching in both hips and down the inner aspect of the thighs, and accompanied with a profuse leucorrhœa, which would diminish in about four hours, when the aching went off. I gave her free doses of quinine and ginger, and that not succeeding, tried Warburg's capsules without effect; whereupon six grains of solid extract ergot, with three of quinine, were ordered every hour for three doses, commencing at 2 P.M. Both the aching and the leucorrhœa were checked on the first day of this treatment.

In the treatment of migraine with ergot it has been my practice to administer the fluid extract of ergot combined with an equal quantity of cinchona elixir, to obviate its tendency to cause nausea. Two teaspoonfuls of this mixture is to be taken in water as soon as the premonitory symptoms of the headache are noticed, and the patient is advised to lie down and keep very quiet. If after an hour the headache continues, a second similar dose is taken, and then a third in another hour, if necessary. As nausea is such a general accompaniment of this affection, it is provided that if either of the doses be vomited it should then be taken as an enema in two ounces of water. I have rarely failed to arrest the attacks with this medication, even in long standing cases, and with a preventative course of intestinal antiseptics in the intervals the relief from the malady has often proved permanent.

RESECTION OF THE HYOID BONE FOR RADICAL CURE OF FISTULA COLLI CONGENITA.[1]

By CARL BECK, M.D.,

NEW YORK.

Congenital fistula colli is a condition not frequently met with. Although enjoying unusual opportunities for observing surgical diseases of the neck, during sixteen years of surgical practice, I have treated only six cases. As these fistulæ, as a rule, scarcely cause any trouble, many of them do not seem to come under surgical care.

Three of my cases (all lateral) were cured by repeated application of the galvano cautery; two (one median and one lateral) by division of the fistula and excision of its lining membrane.

The sixth case could be cured neither by galvanocautery nor by excision, therefore I undertook the resection of the hyoid bone. As I have been unable to find a similar case in literature I may give the details:

Mrs. T. M——, forty five years of age, mother of five healthy children, had always been well. Since birth she had suffered from a small opening on the anterior margin of the right sternocleidomastoid muscle, about two inches above the upper border of the sternum, nearly in the median line of the thyroid cartilage. Occasionally a gelatinous fluid was discharged from the fistula canal. Repeatedly it had closed spontaneously and remained closed for several weeks. This condition had never given any trouble until January, 1893, when she noticed a dry sensation in her pharynx extending over the sublingual region. At times during the past months she has been hoarse.

By treatment with the galvano cautery, at the special department for surgical diseases of the neck at the German Poliklinik, I obtained temporary occlusion. But, after having introduced the needle ten times without a permanent result, in March, 1893, after having divided the fistula I excised the inner walls of the fistula, which seemed to end in the periosteum of the hyoid bone; then with two tiers of sutures I united the edges of the wound and perfect union took place, until four weeks later the *status quo ante* became restored.

Once in a while the patient complained of severe pain in the hyoid region, which yielded temporarily to anodynes and wet applications. More or less hoarseness was noticeable repeatedly.

Inspection and palpation of the pharynx, as well as a laryngoscopical examination, revealed nothing but a hyperæmic condition. Injections of milk into the fistula did not show inside.

As the patient herself demanded a second operation, I therefore, after having divided the fistulous track again, more carefully than before examined the hyoid bone. After having scraped away a small portion of its periosteum, my probe happened to slip behind the bone, where a cavity seemed to be present. To ascertain this, I cut out a small piece of the hyoid bone; behind it I found a cavity the size of a small nut, the fibrous walls of which were defined by the posterior surface of the hyoid bone, and the mucous membrane of the root of the tongue.

I now became convinced that a successful result could only be obtained by exposing the cavity entirely, which I could only achieve by resecting the whole hyoid bone on the right side, that is, cornu majus, minus, and the middle portion. This was done with little difficulty by loosening it from its muscular attachments almost bluntly. Then the fibrous tissue was extirpated. The bleeding was insignificant. Three tiers of catgut sutures united the edges of the wound. Into the most dependent part a small strip of iodoform gauze was introduced, to prevent retention of secretion.

The whole neck was then immobilized by a large piece of absorbing moss-board, which, after being slightly dipped into an antiseptic solution, adapts itself to the contours of the body like a plaster of-Paris dressing. The bandages surrounded the thorax and head. Three days later the gauze was removed, as the secretion was very scanty. Seven days after, recovery was perfect and has remained so ever since.

The microscopical examination showed the walls to consist of fibrous tissue, partially covered by cylindrical epithelium. The excised walls of the fistula contained the same elements.

The incision was first made parallel with the trachea. But when I had made up my mind to resect the hyoid bone, I added a transverse incision above the same to the extent of about two inches. Interference with deglutition, speech, or respiration was not noticed Hoarseness and dry sensation have disappeared. I therefore feel justified in recommending resection of the hyoid bone in all cases of fistulæ where free exposition is required, and especially where a former excision has not proved satisfactory. If the periosteum has been saved, it may be restored later on.

Just as we resect a piece of rib to enter a focus behind it, produced perhaps by a carious or necrotic process, we may take away the hyoid bone.

As a matter of principle we should lay our foci free, so that we can thoroughly inspect and overlook them. In such fractures, where apposition can be made only with difficulty, resection would seem to be preferable also.

New York, March 17, 1894.

THE TREATMENT OF CHRONIC RHEUMATISM.

THE subject of the treatment of chronic rheumatism will always possess interest as long as so many uncured cases exist. Professor Dujardin-Beaumetz has recently delivered a lecture which is entitled "a Critical Examination of the Treatments of Chronic Rheumatism" (*Bulletin général de Thérapeutique*). It presents the results of a wide experience and may be read with profit.

Professor Beaumetz states that one reason of the lack of success in the treatment of chronic rheumatism, is the fact that several different diseases are grouped under this name, when, as a matter of fact, a sharp differentiation should be made.

The maladies described as chronic rheumatism may be grouped under three heads: First, the rheumatism described in 1800 by Beauvais and studied by Charcot and his school, characterized essentially by deformity of the articulations; this type is known as rheumatoid arthritis, or arthritis deformans. In the second group is included articular rheumatism of chronic course, which has succeeded usually an acute articular rheumatism. The third group consists of cases of the rheumatic diathesis. Here the rheumatic poison manifests itself rarely in the joints, but rather by muscular pains, neuralgias, congestions, etc.

The treatment of these three types of diseases is essentially different. Thus, rheumatoid arthritis is a disorder of nutrition, degenerative rather than inflammatory, and dependent on impairment of proper nervous influence. Its course is progressive; it is never cured, and the most one can expect is to stop the onward march for a time. For this purpose, arsenic and iodine are the only drugs which seem to have any effect, and even these do not always accomplish their purpose. Iodine is best given in the form of an iodide, and not over fifteen grains a day are needed. Grasset thinks that bromine is also of service, and he gives a mixture containing, of iodide of sodium, grains ij., bromide of sodium, grains iv., and chloride of sodium, grains viij. He alternates this with a solution of gold and sodium. For the pains and acute exacerbations of the disease, phenacetin is useful. The diet should be rich and nutritive, and should contain meats, green vegetables, wines, and milk. At the same time external medication, in the shape of baths, electricity, and hydrotherapy, is indicated.

In chronic rheumatism which follows the acute articular disorder, the course of the disease is different. Its progress is not steady, but by bounds, each fresh attack of acute rheumatism leaving further impress on the articulations. More can be done therapeutically for this affection. Medically, the use of the salicylates is to be recommended, both to help the chronic and to ward off acute attacks. Beaumetz speaks highly of asaprol, but we have found it unsatisfactory. There are some secret remedies, one of which, "the Pistoia powder," has much popularity in France. It consists of powdered bulbs of colchicum, grains iij., bryonia root, grain j., betoine, grains vij., gentian, grain j., chamomile, grain j. A powder containing these constituents is taken twice a day for a very long time; and herein lies the secret of success in the medication of rheumatism. The antirheumatics must be used persistently for many months. Another plant whose virtues are much vaunted is the *fleur de fève;* but of its precise value Beaumetz admits he knows little.

But the essential cure for chronic rheumatism lies, after all, in external measures. Of these the most important is massage, next electricity, while the water treatment can be effectively combined with the other measures. Naturally the French speak of the springs of their own country, and of these, Dax, Aix, and Bourbonne are the best. As to food and drink, Dr. Beaumetz does not altogether forbid wines, but recommends a mixed diet with vegetables preponderating, the bowels are to be kept open with laxatives, and the kidneys kept active by diuretic drinks, such as milk, white wine, etc.

In the third form of chronic rheumatism, the rheumatic diathesis, the treatment is essentially dietetic and hydriatic. By means of the thermal waters and a careful alimentary hygiene, excellent results can be obtained. Salicylate of soda, asaprol, and phenacetin are useful in relieving pain. But it is warm bathing which seems to be especially efficacious. The results are due, it is now admitted, not to any special quality in the water, but simply because it is warm and abundant. As to the diet, it is necessary to avoid all ptomaïne-producing foods as much as possible, and Beaumetz recommends approximately a vegetarian diet.

ANTI VIVISECTION AGAIN.

AN organization having the simple and unadorned title of "The American Association for the Spread of Knowledge upon the Extent and Existing Methods of Vivisection," is sending out circulars to the following effect:

"The American Association for the Spread of Knowledge upon the Extent and Existing Methods of Vivisection respectfully asks your assistance, in its efforts to prevent the infliction of unnecessary suffering on the animals used in the laboratories, in class demonstrations, and by medical students.

"Believing on good evidence, which we shall be happy to submit to you, that vivisection is often practised in a needlessly cruel manner; convinced that many abuses exist which could be reformed without any loss to science; knowing that the young student passes through a period of insensibility to the sight of suffering, a condition from which the mature physician is fortunately exempt; we solicit your co-operation in our efforts to save animals from useless torture."

The circular is anonymous, no names of secretary or officers being given.

The statement is made that "the medical student passes through a period of insensibility to the sight of suffering." The actual facts are, as any physician will testify, that during a period of three or four years, the medical student sees perhaps a dozen anæsthetized animals on which demonstrations of the circulation, reflex action, and digestion are made. The total period of time occupied by seeing these anæsthetized animals amounts perhaps to five or six hours. Is it possible that any degree of moral insensibility is induced by this experience? We believe not, and that on good evidence. We have no doubt, from the tone of the anonymous circular, that the writer, who, for all we know, is also the "Association," is perfectly sincere and well-meaning. But we can assure her that she is mistaken. With so many manifest evils and so much unquestionable suffering in this world, it is most unfortunate to find philanthropic endeavor so misdirected and uselessly wasted. Let her see what keen and constant suffering exists in consequence of alcoholism, disease, poverty, vice, bad education, and home life in city tenements.

A VOICE FROM YOUNGSTOWN.

A most curious article has appeared in the *Journal of the American Medical Association*, from Dr. John E. Woodbridge, of Youngstown, O. The writer tells the story of twelve long years of labor during which he has tried to prove to an unresponsive profession that he has a means of surely aborting and curing typhoid fever. The doctor has evidently worked hard for his cause. He has been to New York on invitation of the mayor, and spent a week trying to get an opportunity to test his remedy here; failing in this, he went to Philadelphia and tried for ten days to secure attention there. He next attacked Chicago, with equal lack of success. Finally he struck an epidemic at Ironside, Mich., and then he was allowed full opportunities. He cured all his cases in ten days, and returned with letters of indorsement in his pocket from the local physicians. He finally cites over forty cases, in all of which he checked the fever by the tenth day.

Dr. Woodbridge, however, refuses to divulge his remedy, and it is surprising that any reputable medical journal should give publicity to his claims. Surely he cannot treat all cases of typhoid fever himself, and if his remedy is genuine thousands of persons are dying because he will not reveal his specific.

As a matter of fact, it is no uncommon thing now for a physician to have forty or fifty successive cases of typhoid fever without a mortality; and we may allow this to Youngstown's modest claimant, laying aside all question of diagnosis, good taste, and casuistics.

Decrease of Typhoid Fever in Paris.—The number of deaths from typhoid fever in Paris in 1893 was only 633, as against 1,035 in 1886, and 2,120 in 1880. In 1869 the death-rate from this disease was 53.4 per 100,000, in 1882 it was 147, and in 1893 only 25.7. This diminution is attributed to the increased supply of pure water and to the diminished consumption of water from the Seine. At present the supply of water is at the rate of about thirty gallons per day to each inhabitant.

THE PHYSICIAN'S WIFE.

We are quite content to believe that anything written about the physician's wife will find much currency in professional circles. The novelty of the subject is of itself an invitation to attention and the circle of readers is destined to increase beyond the range of an ordinary treatise on medicine or medical things and interest both sides of every household containing a married doctor. All of us know who and what the wife of the doctor is, what, at least, she is to us; but it is refreshing and edifying to share her innermost consciousness of the fitness of things, and read what she can write about herself, her joys and sorrows, her trials and triumphs, and find her solving the problem of the unknown quantity in medical literature. Such a book has been written[1] by the wife of a physician who evidently knows her subject and can tell her interesting story. The taking title, the chastely modest style, the domestic complexion of the story, and the spirited and graphic description of life scenes make it a very entertaining little book, not only in the few spare recreative hours which fall to the lot of all good wives, but at those times when, nursing a lukewarm dinner, she is nervously watching and perhaps fretfully waiting for her absent and apparently heedless spouse.

We are informed that hitherto the physician's wife has been unnoticed in history, has been the un-recorded factotum of the doctor's make-up, and in fact has not received her due share of recognition. So far, however, has she been vindicated under existing circumstances that no doubt can be entertained as to her present status; indeed, in some parts of the book the author is almost inspired with a compensatorially retaliative spirit in picturing some of the weaknesses of the big man of the house when he is sick and unreasonable, when the wife is so indiscreet as to get sick herself, when the flower-bed needs watering, when the potatoes must be hoed, when the night-call must be answered, and last but not least, when the bills must be collected. Admitting everything, we are still on the side of the doctor, in all his troubles, foibles, and trials, and not necessarily ungallant to his faithful, painstaking, patient wife. We know it is hard work for both, the one to work and worry, the other to watch and wait. But our author has succeeded in so effectually harmonizing apparent differences that we are presented with a refreshingly delightful picture of the home life of the country doctor, which can well offset the trying experiences of his equally worked but more envied metropolitan brother. In fact, the background of dark hours, disappointed hopes, and delayed collections gives a bolder relief to the higher lights in the picture, wherein are shown the better purposes of a life work devoted to humanity and the alleviation of human suffering. And altogether the picture is a pleasant one to contemplate as reflected from the fireside of a practitioner who works for the work's sake.

We agree in believing that the doctor owes a great deal to his wife, more than he is generally willing to admit. She is his ready helper in all the times of his need. To her he owes his warm meal at the unseasonable hour, the answer to his ever-ringing office bell, the waking of the tired sleeper, the helpful preparations for the mid-

[1] The Physician's Wife and the Things that Pertain to Her Life. By Ellen M. Firebaugh. Philadelphia: The F. A. Davis Co. 12mo., pp. 186.

night call, and the cheerful welcome after the long wait. In the country she is oftentimes his druggist, bookkeeper, and cashier. To these privileges she sacrifices many a pet scheme for enjoyment and is forced to accommodate herself to the irregularity of professional business. The doctor, his wife, and his horse are partners in the eternal jog. But even this lot must be accepted in becoming thankfulness, perhaps, as it is one of the associated conditions of good business and professional success.

Then again the doctor's wife is the only one who takes kindly to the recital of the remarkable case. She will listen when all others have been excused. To her the man must be the hero, save when she is sick herself. His skill is nothing to her then. She of all others needs no medicine when ill. Too often she gains a husband and loses a doctor. But he dare not tell even her that he does not care to experiment too near home. There is also a little of that familiarity of method unavoidably known to her in placeboic ventures which shakes confidence in the exposed fetichism and invites a becoming contempt of the seemingly miraculous. It is the old story of tasting the forbidden fruit of knowledge. The patient in the end knows too much and the doctor too little.

But our wives, God bless them, understand us better than anyone else, and the time has come for us to know them equally well. Their love, sympathy, interest, and encouragement make us what we are. Mrs. Firebaugh appreciates all from her wifely standpoint and tells it with a sweet pathos and chaste humor which gives her effort its main charm. We visit the doctor's patients, we hear their stories, appreciate their oddities, sympathize with their distresses, and become a part of the landscape as we drive with him through fresh country lanes, past fragrant woods, and over breezy hills. Many a young bachelor in a metropolitan flat whose only conveyance is the crowded street-car would gladly shift situations and try his luck at being the partner of such a better-half.

A "LIVELY" VIEW OF APPENDICITIS.

Our jocular contemporary, *Life*, is not humorous when it dabbles in surgical aphorisms, as witness the following editorial lucubration:

"Is it not nearly time that some restriction was put upon the disposition of surgeons in this town to slice open their fellow-creatures in the interest of the complaint called appendicitis? That late absurd and lamentable operations have cost the lives of useful citizens will strengthen our opinion, which begins to be pretty generally current, that appendicitis is epidemic in the minds of the metropolitan surgeons, and that human life would be safer in New York if the operation was forbidden except by order of a court. The public knows altogether too much about appendicitis, and the doctors altogether too little. Two-fifths of the genuine cases result from scare in the patients, and one or two more fifths of all the cases exist only in the imaginations of the surgeons. The cure of such legitimate cases as are left is not worth what it costs. Appendicitis is played out. The invention of the operation for it has changed a very rare malady into a common and dangerous disease."

The editor of *Life* is at his best when he playfully points out the deleterious effects of a sustained dietary of empty tomato cans on the morals of the goat. Let him stick to that reliable joke, and cease ventilating his ignorance of legitimate surgery. He is undoubtedly "funny" when he talks medicine. But that is only because he means to be serious.

News of the Week.

Death of Dr. A. A. Ransom, of South Orange, N. J.—Dr. Anson Amesbury Ransom, of South Orange, died on Sunday evening. He was born in Chemung County, N. Y., seventy-one years ago. He was a graduate of the College of the City of New York. He was a charter member of Century Lodge No. 100, F. and A. M., of South Orange. A widow and two daughters survive him.

The Death of Dr. M. K. Hogan.—At a special meeting of the Medical Board of St. Vincent's Hospital, held on February 26, 1894, to take action on the death of Dr. M. K. Hogan, the following resolution was adopted: "The members of the Medical Board of St. Vincent's Hospital, having learned with profound sorrow of the death of their highly esteemed colleague, Dr. M. K. Hogan, on whose long and faithful service as attending physician, on whose rare ability, and on whose devotion to the sick poor, all the officers and the sisters of the hospital have placed the greatest value, have resolved to attend his funeral in a body, and through the medical journals to make known their appreciation of the high personal and professional character of their late associate. J. A. McCreery, M.D., *Secretary*."

Postponement of Congress for International Medicine.—Dr. Emil Pfeiffer, permanent secretary of this body, writes us that owing to the holding of the Eleventh International Medical Congress at Rome this month, the next session (thirteenth) of the Congress for International Medicine will be held in Munich in 1895.

Dr. J. Mount Bleyer, of New York, has been made a Fellow of the Royal Academy of Medicine of Naples.

The Advantages of a Cheerful Disposition.—In a specimen advance proof of a forthcoming autobiographical dictionary of "Physicians and Surgeons of America," one gentleman gives the following example of cheerfulness under difficulties: "My life has been a struggle from the beginning; but I have laughed at difficulties, and have whistled and sung when some others would have died. Twice in life I have lost all I had, and on the night following a knowledge that I was ruined financially, I went to bed and was asleep while my dear wife was preparing to retire. There is but one thing that can conquer me, and he is the conqueror of all—Death. 'Ay, there's the rub!'"

American Surgical Association.—The annual meeting will be held in the lecture-room of the medical department of the Columbia College, 1325 H Street, N. W., Washington, D. C., May 29, 30, 31, and June 1, 1894. The special subjects announced and discussions thereon are: "The Surgical Treatment of Empyema," by John Ashhurst, Jr., M.D.; discussion by Drs. N. P. Dan-

dridge, C. B. Nancrede, T. F. Prewitt, and De F. Willard. "Methods of Teaching Surgery," by J. S. Billings, M.D.; discussion by Drs. J. C. Warren, N. Senn, W. W. Keen, E. M. Moore, W. T. Briggs, and Hunter McGuire. It is desired that the discussion of this paper should be participated in by the Fellows generally. "The Surgery of the Kidney," by L. M. Tiffany, M.D.; discussion by Drs. M. H. Richardson, H. H. Mudd, C. H. Mastin, and Ford Thompson. "Methods of Controlling Hemorrhage in Amputation at the Shoulder," as illustrated by three cases of amputation at the shoulder-joint and of the entire upper extremity, by W. W. Keen, M.D.; discussion by Drs. Roswell Park, C. B. Porter, and J. William White. Paper by Hunter McGuire, M.D. Paper by Joseph Ransohoff, M.D. Fellows who desire to present volunteer papers are requested to send the titles of the papers to the address of the Business Committee, 1429 Walnut Street, Philadelphia, not later than April 18, 1894.

An Eccentric Physician —Professor Zakhärin, of Moscow, who attended the Czar during his recent serious illness, is almost as well known in Russia for his eccentricities as for his eminence as a physician. The *British Medical Journal* states that when he is called to attend to a patient special arrangements must be made in the house; all dogs must be kept out of the way, all clocks must be stopped, all doors must be thrown wide open. The professor on entering begins a process of gradual undressing, leaving his furs in the hall, his overcoat in the next room, his goloshes in the third, etc. He insists on perfect silence on the part of the afflicted relatives, except in reply to his questions, when their speech must be literally "Yea" and "Nay." He has a theory which he expresses in the maxim, "Take a rest before you are tired," and accordingly he sits down every eight or ten steps. His demeanor toward doctors with whom he happens to be unacquainted makes him greatly feared by them, and some eight years ago a kind of public agitation was got up in opposition to him in which many hundreds of doctors took part. Resolutions were passed and addresses were presented, and echoes of the gathering storm made themselves heard in the press. These manifestations of feeling were speedily repressed in a way characteristic of Russia. The then General-Governor of Moscow, Prince Dolgorukoff, sent for the editor of the medical journal in which the addresses were printed, and told him that if he published a word more about Zakhärin, he would have to leave Moscow in twenty-four hours' time. His eccentricities, however, cease at the bedside of his patient; there he is courteous and considerate, most painstaking and minute in his examination, and very thorough in his treatment. So successful has he been in his profession that he is believed to be worth some half-million sterling.

College Athletics, and the Drinking Habit.—Dr. John Leverett, of Binghamton, N.Y., writes: In the RECORD of March 3d, there is an article on the editorial page which I was very sorry to see in a scientific journal since it so wofully misrepresents certain facts. It is headed "College Athletics and the Drinking Habit." Whatever may be said in regard to the drinking habit in Yale and Harvard, and no one deplores that habit more deeply than myself, the following rules of training, which are familiar not only to the members of the various teams, but to almost every man who takes a lively interest in watching the games, will, I think, remove from athletics the onus put upon them by the article I have mentioned. In American colleges the athlete, when in training, is forbidden the use of any alcoholic drinks. This differs from the training in vogue at the English universities, I am informed, in that the English rules prescribe a certain amount of beer per day. Besides this our college athlete is forbidden to smoke or use tobacco in any form, is required to be in bed in good season every night, and is not permitted to indulge in excesses of any kind. These are not in any sense college rules, but rules to which the athlete submits himself voluntarily, and I believe them to be lived up to very strictly in almost every case. I write this to you, believing that the RECORD is always reliable and that you will be glad to correct the mistake.

The Cincinnati Academy of Medicine, at its regular annual election, chose the following officers for the ensuing year: *President*, Dr. E. G. Zinke; *1st Vice-President*, Dr. Joseph Eichberg; *2d Vice-President*, Dr. O. D. Norton; *Secretary*, Dr. David De Becla; *Treasurer*, Dr. George E. Jones. The Academy will hold its regular annual banquet on March 19th. The retiring president is Dr. C. G. Comegys. A chair of laryngology and rhinology has been added to the Cincinnati Hospital, and Drs. Max Thorner and W. M. Roads elected to the chair. Also a chair of Neurology, with Dr. J. T. Whittaker and Dr. Herman H. Hoppe to fill the chair alternately.

Mississippi State Medical Association.—The twenty-seventh annual meeting will be held Wednesday, Thursday, and Friday, April 4th, 5th, and 6th, in the Senate Chamber, at Jackson, commencing at eleven o'clock, A.M., Wednesday, and closing at two P.M., Friday.

The Municipality of Berlin has appointed Councillor Marggraff and Dr. Strassmann, Privat-Docent of Forensic Medicine, delegates for the city to the International Medical Congress.

American Medical Association.—The committee of arrangements has secured Odd Fellows' Hall Building, corner Market and Seventh Streets, San Francisco, for the meeting, June 5, 1894. Assembly Hall, for the general meeting, has a capacity of 1,500; the twelve smaller halls, for section work, range in capacity from 500 downward, with committee rooms adjacent. The engagement carries three of these rooms on Monday for accommodation of associate organizations, as that of the editors, colleges, etc. The banquet-room on the ground floor, 65 x 95 feet, will be devoted to exhibition purposes, for which it is admirably adapted, and has been secured for the entire week, that exhibitors may have Monday in which to place their goods, and Saturday in which to remove them. Headquarters for the Association have been located at the Palace Hotel, corner Market and Montgomery Streets, only four blocks from the place of meeting. The following hotels, centrally situated and convenient to the place of meeting, have quoted special rates for members and their families, which will apply during the entire stay of the guests, who should, upon registering, signify that they are in attendance upon the meeting of the Association. The rates quoted are for single persons,

the variation depending upon the size, situation, and appurtenances of the rooms, as single, *en suite*, with private bath, etc.; special arrangements will be made for families or parties on timely notice.

Some of the hotels entertain upon the American plan only, some upon the European plan only, and some upon either plan to suit guests. Palace Hotel (headquarters), American plan (rooms and board), $3.50 to $5.50 per day; European plan (rooms only), $1.50 to $3.00 per day; Baldwin Hotel, American plan, $3.50 to $5.00 per day; Baldwin Hotel, European plan, $1.00 to $3.00 per day; California Hotel, American plan, $3.50 and up per day; California Hotel, European plan, $1.50 and up per day; Lick House, American plan, $2.50 and up per day; Lick House, European plan, $1.00 and up per day; Russ House, American plan, $2.50 to $3.50 per day; Russ House, European plan, $0.50 to $2.00 per day; Occidental Hotel, American plan (only), $2.50 and up per day; Hotel Pleasanton, American plan (only), $2.50 to $5.00 per day. Grand Hotel, connected with the Palace by a glass-enclosed bridge across New Montgomery Street, European plan only, $1.00 to $2.00 per day. In addition there are many other hotels, boarding-houses, lodging-houses, and restaurants contiguous to the place of meeting, where one can be made happy and comfortable at less cost. Post Office Section K, is located in the Palace Hotel, on the office floor, adjacent to the registration-room, where members can receive all mail matter by having it so addressed.

General Addresses at the International Congress.—The following are the titles of the addresses to be delivered in general session at the Rome Congress: V. Babes, of Bucharest, on the "Position of the State in Relation to the Results of Modern Bacteriological Investigations;" G. Bizzozero, of Turin, on "Growth and Regeneration in the Organism;" Brouardel, of Paris, on the "Warfare against Epidemics;" Cajal, of Madrid, on the "Morphology of the Nerve-Cells;" Danilewsky, of St. Petersburg, on the "Biological Rôle of Phosphorus in its Organic Combinations;" Michael Foster, of Cambridge (England), on the "Organization of Science;" Th. Kocher, of Berne, subject not yet announced; A. Jacobi, of New York, "Non Nocere;" S. Laache, of Christiania, on "Idiopathic Hypertrophy of the Heart and Degeneration of the Cardiac Muscle;" H. Nothnagel, of Vienna, on the "Adjustment of the Organism to Pathological Changes;" B. J. Stokvis, of Amsterdam, on "Chemistry in its Relations to Phamacology and Materia Medica;" Rudolph Virchow, of Berlin, on "Morgagni and Anatomical Views."

The Healthiest Town in England is Croydon, which has a mortality of only 11.2 per 1,000 per annum. In Brighton, for the week ending February 21st, there was a death-rate of 15.8, and in London 18.6. In the latter town there were 22 deaths from influenza for the week, an increase of three over the preceding week.

A Hygienic Exposition.—The Ninth Exposition of Hygienic and Food Products will be held in Rome in May. This annual exposition is organized by the International Association for the Advancement of Hygiene, having its headquarters in Brussels. Professor Baccelli, President of the International Medical Congress, has accepted the chairmanship of the governing committee.

The Cholera is increasing in Tripoli, and Malta has imposed a quarantine of fifteen days on all vessels arriving from Tripoli, in view of this recrudescence of the disease. Advices from Constantinople also report a somewhat alarming increase of the cholera.

Inhalations of Mint in Pulmonary Phthisis.—Dr. Carasso, Director of the Military Hospital in Genoa, reports a number of successful cases in the treatment of pulmonary tuberculosis by inhalations of mint essence. The results were good, not only in the early stages, but even after large cavities had formed and when the sputa were loaded with bacilli. Fever, when present, disappeared in a few days; the cough and expectoration were notably diminished, the night-sweats ceased, and the bodily weight increased. The bacilli disappeared entirely from the sputum in periods varying in the different cases from two weeks to two months. The physical signs in the lungs also improved and became perfectly normal in several instances in which no destruction of tissue had taken place. Just how much of this amelioration should be attributed to the inhalations of mint is, however, uncertain, for the patients were subjected to a system of forced feeding and to the internal administration of creosote.

Bellevue Hospital Medical College.—Dr. William P. Northrup has been appointed Adjunct Professor of Diseases of Children, Bellevue Hospital Medical College.

The Death of Mrs. Charles L. Dana.—The many friends of Dr. Charles L. Dana, and of his wife, Lilian Farlee Dana, will be shocked to learn of Mrs. Dana's death in Bermuda last Saturday. Her death was due to injuries received in jumping from a carriage to save her little daughter Elsie, who had fallen from the vehicle. Elsie was driving at the time and managed the horses so well that the coachman forgot to hold on to the ends of the reins. Suddenly the horses started forward in affright at some object they were passing, and Elsie was dragged over the dashboard, apparently directly under the wheels, but really under the centre of the vehicle, where she lay uninjured, but stunned. The driver attempted to catch her as she fell, and he in turn fell into the road. The horses were now tearing down the road in a mad gallop. Mrs. Dana looked back, and, seeing her child lying motionless, sprang out of the carriage. As she jumped her dress caught, and she struck the coral road on her head. The coachman carried her to a neighboring house. Then he pursued the runaway horses, overtaking them about a mile and a half from the scene of the accident. The old nurse remained in the carriage, motionless from fright. The little girl was merely bruised. The news was at once sent to Dr. Dana, but he did not know that his wife was dangerously ill. He cabled to his friends in Bermuda to let him know every day of his wife's condition. The reports grew more favorable each day for a week, when they began to hint of a relapse. The doctor sailed on the 8th inst. for Bermuda, and arrived there on Saturday, the day on which his wife died. She was unconscious from the time of the accident. Mrs. Dana was born in this city thirty-five years ago. Her father, G. W. Farlee, is a retired banker, and her grandfather was Mayor George Opdyke.

The Recently Elected Vice-President of Brazil is a medical man.

Society Reports.

ROYAL MEDICAL AND SURGICAL SOCIETY (LONDON).

Nerve-stretching and Nerve-splitting in Localized Interstitial Neuritis.—Dr. K. McLeod read a paper on the above subject and said that his experience warranted him in presenting the following conclusions: 1. The operation of nerve-stretching had been followed by decided relief in a large proportion of cases of leprous neuritis which had been subject to this method of treatment. 2. The benefits conferred consisted in the relief of suffering, the restoration of sensibility, the return of muscular power, the healing of ulcers, and general improvement in the nutrition of the affected parts. 3. The relief obtained by the proceeding appeared to depend on the removal of pressure and tension on nerve-fibres caused by the products of inflammatory disease which had taken place in the ensheathing connective tissue of the trunk. 4. When these products had undergone organization and the enveloping material had become sclerosed, longitudinal incision of the sheath followed by manipulation and stretching gave reasonable promise of more complete relief than stretching alone. 5. This process of splitting sclerosed nerve-trunks had been attempted with success in a sufficient number of cases to render further trial justifiable and desirable. 6. In cases of non-leprous neuritis these procedures were more likely to be followed by radical and permanent improvement than in cases of anæsthetic leprosy. 7. In no instance had either the stretching or splitting of nerves been productive of any inconvenience or harm.

BERLIN MEDICAL SOCIETY.

The Internal Organs in a Case of Pernicious Anæmia.—Dr. Baginsky showed the internal organs of a child who had died from pernicious anæmia. The brain and cord were markedly anæmic. The heart showed enormous dilatation and fatty change in the musculature. The parenchyma of the kidneys and liver were in an advanced stage of fatty degeneration. The liver and spleen were soft and very much enlarged, and in the latter many follicles were seen.

The suprarenal capsules were apparently normal. The walls of the stomach were very anæmic, the marrow of the bones was very light-colored, and the Haversian spaces prominent. The child was three and a half years old, and had always been a weakling, but the symptoms seemed to develop rapidly after a blow on the face, which was followed by great hemorrhage. This was followed by symptoms of infection, such as fever, diarrhœa, cough, and rapidly developing anæmia. The proportion between red and white corpuscles fell to 100 to 1, the hæmoglobin diminished to seventeen per cent., and specific gravity fell to 1.037. An abscess then developed about the knee, and death soon followed a marked exacerbation of all the symptoms.

ACADEMY OF MEDICINE (PARIS).

Transperitoneal Nephrectomy.—Dr. Le Dentee reported a case of transperitoneal nephrectomy for cancer of the kidney in a patient forty one years of age, who had hæmaturia for nearly a year, and who latterly began to have a progressively increasing swelling in left flank, associated with left-sided varicocele. After median laparotomy the first difficulty presented itself from the adherence of the colon to the tumor, but when these adhesions were broken it was seen that the peritoneum glided easily on the neoplasm. The peritoneum having been incised, enucleation was easy. The rest of the operation was then very simple. Recovery was complete. The entire kidney was extirpated. Microscopical examination showed the new-growth to be carcinoma of embryonic type.

Mortality of Tuberculosis.—Dr. Lagneau said that his investigations into the relationship existing between occupations and the development of tuberculosis showed that the greatest number of deaths from phthisis occurred in workers exposed to irritating substances in the respired air. In Switzerland 10 out of 100 stone-cutters die from phthisis. In England, of 1,000 deaths occurring in these workers, 340 were from phthisis. Tuberculosis makes cruel onslaught likewise in those individuals who habitually occupy a bent posture at their occupations, and in those who live sedentary and intellectual lives. Of 1,000 deaths in Italy among students and seminarians, 459 died of phthisis—that is, nearly one-half. In England, of a similar number of deaths in printers, 430 died of phthisis.

On the other hand, statistics show that it is quite exceptional for this disease to be the cause of death of those who live in the open air. In Switzerland, of 1,000 deaths occurring in out-door laborers and farmers, not more than one or two die from phthisis. A similar number of deaths in Italy among shepherds and farmers show only from forty-four to fifty-five deaths. In France the sanitary statistics gathered from six hundred and sixty-two towns show that the more the population is conglomerated, so in proportion are the inhabitants gravely affected with tuberculosis.

Ovariotomy in the Puerperal State.—Dr. Pinard reported a case in behalf of Dr. LeRoy des Burres. The patient was a young woman, twenty-nine years of age, who after her accouchement, two months previously, had had a series of accidents in the shape of infection. First, a subacute peritonitis developed, then a pleurisy, and later phlegmasia alba dolens. Shortly afterward the abdomen showed the presence of a large swelling. A diagnosis of suppurative cyst of the ovary was made, and ovariotomy was performed. The operation demonstrated a purulent pouch containing nearly a quarter of a litre of pus. Immediately after the operation the sinister symptoms disappeared, and the patient left the hospital twenty days after the operation completely cured.

CONGRESS OF RUSSIAN PHYSICIANS.

Bromethyl and Chloroform Narcosis.—Professor Pawloff in discussing the narcosis resulting from bromethyl and chloroform reached the following conclusions: 1. The narcosis comes on in a relatively shorter time, about two minutes, and the patient does not pass through a stage of excitation. 2. It requires a very small amount of bromethyl, about 5 grammes, to bring about full anæsthesia. 3. The narcosis is not attended by any disagreeable manifestations. 4. A small amount of chloroform is needed to keep the narcosis up. 5. There follows no bad after-effects.

Dr. Pawloff says he begins the narcosis by bromethyl, about 5 grains are required, and then maintains the narcosis by chloroform, and about 16 grammes of the latter is required to keep up the narcosis for fifteen minutes.

VIENNA MEDICAL CLUB

Acute Anterior Poliomyelitis.—Dr. Redlich said he had recently had the opportunity to examine the spinal cord of a five months' old child who had died from acute anterior poliomyelitis, and that he was enabled to corroborate the opinion which is now commonly held, that the blood-vessels are the starting-point of the disease and not the ganglionic cells or supporting framework, as was formerly believed. The case detailed was remarkable for the fact that lesion was not confined to the cord, but showed small areas of inflammation in the medulla and great brain. The phrenic nerve likewise showed spots of softening. The pathologic changes would therefore point to an infectious process as causative of the disease; as the result of such an infection the lesion may be in several locations, even involving the nerves, producing a multiple neuritis, a condition sometimes found associated with anterior poliomyelitis.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, February 2, 1894.

WILLIAM H. DRAPER, M.D., CHAIRMAN PRO TEM.

Photographs of Colitis.—DR. FRANCIS DELAFIELD presented a series of photographs of colitis and made the following running remarks thereon: In the simplest form of colitis, the so called simple catarrhal form, we know that the membrane is congested, that there is more or less exudation of serum, that there is more or less swelling of the stroma between the tubules and the glandular coat, and that there is increased production of mucus; none of which things are much changed after death. We know that this condition is not at all fatal in adults, but that it destroys life in children, and that in children there is apt to be added swelling of the solitary glands in the walls of the colon.

The pictures which I first present you simply show those changes.

The Purulent Form.—Passing on from the simple catarrhal form of colitis, we come to the purulent form, in which there is considerable infiltration of pus cells between the tubules of the glandular coat and in the connective-tissue coat. This is a very much more serious lesion than the former; it is one which is apparently quite frequently fatal. It seemingly belongs to the class of streptococcus inflammations. In some cases there is added necrosis to the suppuration, resulting in the formation of ulcers. These photographs are illustrations of that form. The last one illustrates purulent colitis complicating typhoid fever, with necrosis, then forming an ulcer, while the others illustrate simple infiltration without the formation of ulcers. One of them shows a rather curious condition, a sort of drawing together of the muscular coat of the intestine, so that the colon was thrown up into ridges.

Croupous Colitis.—Then we come to the so-called croupous colitis, which is, of course, a combination of the exudative inflammation with necrosis, the disposition to necrosis being quite well marked. In the human subject we very seldom see such a croupous colitis until after it has lasted a number of days and the changes are fairly well marked; but it is possible to produce such a colitis artificially in animals by injections of corrosive sublimate, so that we can see it at an early period. Here is a picture showing the artificial form in a dog, produced by subcutaneous injection of corrosive sublimate, the animal having been killed three or four hours later, when the colon showed the beginning of the disease. It shows a layer of fibrin on the surface of the tubules and necrosis in the outer ends of the tubules. In the human subject the condition is usually much farther advanced, and we find the colon coated with fibrin, either continuously or in patches, and on making cross sections of the colon we see the infiltration with fibrin, either in the connective-tissue coat beneath the tubules, or involving the tubules as well. As soon as it involves the tubules these are practically lost and are seen no more. That is to be observed in these three figures.

Productive Colitis.—There is another form of colitis which seems to be quite common, and which is often classed with catarrhal colitis, but which appears to be a little different because, besides the congestion and increased production of mucus, there is from the first a growth of connective tissue between the tubules. The process is somewhat analogous to a true broncho pneumonic inflammation, from the first of productive character, and very often there is added to it a necrosis which is productive of ulcers of certain form. The gross appearance of such a colon is seen in this photograph. It also contains a very good example of the solitary ulcer, an ulcer with overhanging edges, not extending below the glandular coat. You see between the tubules considerable increase of tissue. Here are several other photographs of the same condition. A special feature of such a productive colitis is its tendency to be chronic from the first; to be a productive, not a simple, inflammation from the commencement.

A colitis of this character may at any time become the seat of purulent inflammation, and then we get such a mixed picture as we see here—the whole inner surface of the colon looking as if it were raised up into nodules, and cross-sections of the nodules showing thickening of the connective tissue coat and the more recent covering of this with pus.

We come to amœbic colitis, or colitis which is apparently due to the presence of amœbæ in the colon. I think we are yet very far from knowing all the things which an amœbic colitis can do, but there are certain striking features, namely, that the disease terminates in one, two, or three weeks, that the patients are very sick from the first, and the most marked change found at autopsies is necrosis of the colon; a necrosis involving not merely the glandular coat, but often extending way down to the peritoneal coat. It is the most necrotic of all the necrotic forms of colitis. Here is a photograph which shows the inner surface of such a colon at the twenty-first day. The colon is thrown up into ridges, and cross sections through these ridges show the necrosis extending down to the peritoneal coat. That is one case of the very acute form with extensive and deep necrosis. Then there are other cases in which the necrosis is not anything like as extensive, nor anything like as deep, but simply forms ulcers with overhanging edges. Here is an example of that. It is a colitis of twelve days' duration. Then there is a third form of amœbic colitis, which begins very gently. The patient at first has apparently an ordinary diarrhœa—four or five fecal passages a day—the diarrhœa gets no better, the man continues to run down, gets fever, and goes on thus a long while—weeks or months—and finally dies. Of course in all these three forms there may be abscess of the liver, and, indeed, there is very apt to be. In the long-continued cases there is time for a great many changes to take place in the colon. There are ulcers in various stages, some belonging properly to the amœbic condition; there is more or less catarrhal inflammation, and more or less productive inflammation, and also ulcers which seem to be rather streptococcus ulcers than amœbic ulcers. In the photograph shown we see the gross appearances of the colon where the disease lasted forty days.

I do not think we really know much about amœbic colitis; we are only just beginning to learn about it, and at present we can speak no further than of what we have seen. How many people have the disease and get well, we do not know at all. It is not always possible to find the amœbæ in the stools. Living amœbæ are easily found; dead ones are not. It is easiest to find them in abscess of the liver.

DR. PEABODY remarked that in a case at Bellevue Hospital, several weeks ago, they drew pus from an abscess of the liver, found no amœbæ, but after operation they were found in abundance. There had been symptoms of amœbic colitis which had quite disappeared.

In reply to a query by Dr. Biggs, DR. DELAFIELD said there was nothing characteristic about dead amœbæ in the stools, and that unless live ones were present nothing characteristic of amœbic colitis could be discovered; and DR. BIGGS added that such had also been his experience.

The Treatment of Uræmia.—DR. BEVERLEY ROBINSON read the paper (see page 321).

DR. DELAFIELD being called upon, said: Dr Robinson justly remarked at the beginning of his paper that when he said uræmia he did not mean uræmia. The first question, then, which arises is, What does one mean when he uses this term? For my own convenience I bear in mind two conditions, which may be called, also for convenience, acute and chronic uræmia, although I do not believe that acute uræmia is uræmia at all, and although I think that chronic uræmia is really uræmia. Under the name acute uræmia, which is entirely arbitrary, I include a set of cases with which we are all acquainted. Cases in people some of whom have chronic nephritis, some

chronic endarteritis, some pulmonary emphysema, some chronic endocarditis, who at some time develop a well-marked group of symptoms. They have headache, or involuntary contraction of a group of muscles, or general convulsions, or become comatose, or hemiplegic, or develop a peculiar spasmodic dyspnœa, or they have irritable and uncontrollable vomiting. At the same time that all this comes to pass, the pulse is of distinctly high tension, the arteries contracted; but as the condition goes on to become worse the arteries are no longer contracted, the pulse becomes rapid and feeble, the heart-action rapid and feeble. Now, in the early part of their condition, while the contraction of the arteries still exists, it seems to me one way to relieve them is to dilate the arteries, and it is a matter of choice whether you use venesection, purging, hypodermic injections of morphine, nitro-glycerine, or pilocarpin. If you dilate the arteries in one way or another the symptoms will let up; if you cannot dilate the arteries the symptoms will persist. The arteries will remain contracted, the heart-action will become more and more rapid, more and more feeble; nothing helping, the patients die.

Then there is chronic uræmia, if you may choose to call it such. These patients will have cerebral symptoms, but not very marked; they will have low muttering delirium which alternates with stupor, and it becomes evident that they are getting sicker and sicker; but the pulse is always feeble, is never contracted, there is never any contraction of the arteries. These people certainly do look as if they were being poisoned in some way or other. I do not think the first class do. It seems to me nothing ever does the second set any good except the wet pack, and that, I think, produces only temporary benefit. The patients all die, but instead of dying in a few days, they may not die for a few months with the help of the wet pack.

Blood-letting and Hypodermoclasis.—Dr. J. West Roosevelt wished to say a word about that part of the paper which dealt with blood-letting and hypodermoclasis. It seemed to him that there were certain cases in which these measures were eminently indicated. A striking example was that of a man who was transferred to Bellevue three weeks ago from the Presbyterian hospital, where he had been for some time. He had been a chronic alcoholic. When admitted to Bellevue he was semi-comatose, had intense headache, was delirious, had some muscular twitching, the pulse-tension was very high; there was no general œdema, but moderate œdema of the lungs, slight cyanosis. He bled the man, withdrawing thirty five ounces, and introduced under the skin thirty ounces of artificial blood serum, so called. The urine had previously been drawn and contained fifty per cent. albumin, blood-casts, and hyaline and granular casts; the specific gravity was moderately high; the quantity obtained was two or three ounces. In the course of about an hour after this treatment the patient had ceased to be delirious and went to sleep. The pulse-tension had fallen immediately. Toward morning he began to pass urine, which contained less albumin. By the middle of the next day he was in normal condition, the urine contained no more blood, no more casts, only a trace of albumin.

Dr. Roosevelt did not know why such cases should not be regarded as cases of acute auto-poisoning by something, it did not matter much what. To go to work upon the skin and bowels to get rid of the poison in the blood, whatever it might be, seemed to him a clumsy method compared with the simple one of blood-letting. It did not seem possible that blood-letting could have held the position which it did for so long a time if it had not given temporary benefit. But hypodermoclasis acted in a similar manner, and was very easy to perform. In uræmia, however, one had to deal with many different things, and it was not to be expected that these methods would meet the indications equally well in all cases. In the case related it was evident that the condition of the kidneys was such as could pass off in a short time, and dealing with such a patient was very different from dealing with one who had advanced Bright's disease or extensive disease of the arteries.

Where there was marked œdema, hypodermoclasis could not be used, but if it were absent the method was worth trying. The injection should be made under strict antisepsis. Six to eight ounces could be introduced into the thigh of a man easily, and it was curious to observe the speed with which it was absorbed where the heart action was sufficient. In the case related the thirty ounces were introduced by four injections, and the first quantity had disappeared before the last had been introduced.

Dr. F. P. Kinnicutt, referring to Dr. Delafield's statement that he did not know quite what to call uræmia, said that thought came perhaps to all so far as the name itself was concerned; yet we certainly did see a group of symptoms which were chiefly of a nervous character, and which led us to believe that they were due to retention in the blood of certain poisons which should be eliminated by the kidneys. He thought Dr. Delafield should add to his division another, in which the cases were neither acute nor chronic; cases which presented neither the very low blood-pressure which he had spoken of, and in which serous effusions and other measures were of benefit, but which would certainly end fatally after a time; nor the very acute symptoms, such as convulsions and coma, of the other class. It was an intermediate class suffering from retention in the system of some poison. The digestion was bad, there was known to be nephritis, there were occasional acute attacks of headache, indigestion, vomiting, the pulse was of high tension or increased tension. Such patients got along fairly if their diet and general hygiene were carefully regulated. The speaker assumed that they were suffering from a form of uræmia, but not a very acute form; and they were the cases in which one could do most good by treatment. It seemed to him, therefore, that the division simply into two classes of cases, one in which the patients were going to die, and die pretty speedily, and the other in which very acute symptoms were present, did not represent all we saw of so-called uræmia.

With regard to the treatment of such cases, he thought the mistake was sometimes made of forgetting that a certain amount of blood-pressure was unavoidable. It was necessary in Bright's disease, and could be looked upon almost as a conservative process, and it seemed to him that we should strive in the treatment of the cases to arrive at the happy medium of avoiding very high blood-pressure, which increased the strain upon the heart and endangered the vessels, and that condition of low pressure which, it seemed to him, was even more dangerous than high pressure. We heard a great deal about high blood-pressure, perhaps more than was necessary. According to his observation many medical men felt that the moment the blood pressure was increased it should be reduced at any cost. Looking upon it, as he did, as an unavoidable condition, if not a conservative process, Dr. Kinnicutt thought we sometimes erred in using potent means for reducing it.

The Treatment of Uræmia is the Treatment of Symptoms.—Dr. Peabody thought the treatment of uræmia, diverse as it was, was, after all, largely a matter of treatment of symptoms, and there was one symptom which seemed most distressing of all, namely, convulsions. Convulsions were certainly very distressing to the bystanders, yet they were very amenable to a certain drug, one which he had used a great deal—urethan. Its use in uræmic convulsions was suggested to him by the fact of its success in controlling convulsions in animals caused by strychnine. With this agent he had controlled uræmic convulsions occurring several times an hour, in a patient who was so noisy that he had to be removed from the general ward into a room by himself. He became conscious promptly after subcutaneous injection of urethan, went along all right for a few weeks, then had another attack of the convulsions, which were again controlled in the same way. Fortunately urethan was a perfectly harmless remedy, was freely absorbable, quite unirritating

and painless. Incidentally, he stated that he had controlled the convulsions of chorea of a very severe type by urethan, in a patient who was unable before its use to either swallow or sleep. In a case seen with Dr Bull, of enormous sarcoma of the back pressing upon the cord, causing convulsive seizures and extreme pain in the lower extremities, urethan gave relief which large doses of morphine had failed to do. It was only in cases of uræmia that he had failed to control vomiting by washing out the stomach. Here, it seemed, large doses of caffein alone would succeed.

Dr. Kinnicutt corroborated Dr. Peabody's statement with regard to urethan. He had used it largely, beginning, he believed, about the same time as Dr. Peabody. It could be given in very large doses, amounting to three or four hundred grains in twenty-four hours. He recalled one case of convulsions, not due, however, to uræmia, but to some other cause, and the effect had been remarkable, even after everything else had failed. The patient had had forty convulsions, a dozen or more an hour, yet urethan controlled them absolutely. Three or four hundred grains were given during the twenty-four hours. He had also given it in the convulsions of uræmia, in children and adults, and had obtained striking results. It had also been of decided use in chorea.

Dr. Robinson said, in closing the discussion, that he did not think it made a great deal of difference, from a broad stand-point, whether there was a little more or a little less arterial tension. Indeed, he doubted whether in many cases we could tell by tactile sense, or even by sphygmographic tracings, whether there was arterial tension. Nor did he believe that one could tell as a rule how much longer the kidneys were going to last, nor to what degree the disease in them had advanced; and in practice it was idle to speculate upon this question and let people die when their lives might be saved. Their lives could be saved temporarily, and sometimes permanently, by letting out some blood and introducing some saline solution. He was aware that the treatment produced very little result sometimes, but he did not think it always possible to say beforehand that in a given case it must fail. He thought the trouble with doctors was that, as they grew older, they disliked to interfere surgically with anybody, and sometimes allowed people to suffer on that account when they could be relieved. It was that feeling which led them to object to opening a vein or making transfusion. Scarcely anything was simpler, however, than to take a little blood from the arm and throw a solution into the rectum, which might be done instead of transfusion. It did not matter what one wanted out of the blood; the best chemists failed sometimes to tell what the poisons were, but we knew they were present, and the best way to get rid of them was to abstract a certain amount of blood and replace it by a saline solution, so that the vessels could still have something to contract upon. He wished to impress this point, as he thought it was one of practical importance.

Red Light for Small-pox.—Finsen (*Hosp. Tid.*, No. 27, 1893) has made some observations on the effect of light on the skin. He referred to the good results obtained by Black and others by the exclusion of daylight in the treatment of small pox, but argued that as Widmark has shown that it is the ultra-violet rays which have the strong chemical action, it is not necessary to exclude the daylight, but by using red curtains tightly drawn, or red window-panes, the injurious effects of the light can be prevented. The correctness of this hypothesis was proved by Svendsen, of Bergen, who last summer treated four cases of small-pox in unvaccinated patients by covering the windows with thick red woollen curtains. The patients escaped the suppurative stage: there was no rise of temperature, no œdema. The patients passed from the vesicular stage, which was slightly prolonged, into convalescence, and escaped scarring.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 1, 1894.

D. B. St. John Roosa, M.D., President, afterward A. M. Jacobus, M.D., in the Chair.

Enlarging the Library.—Dr. A. M. Jacobus read a report from the trustees, recommending the erection of a new stack room in the library, and on motion the Academy gave its approval.

Dr. C. L. Dana, by request of the Council, had consented to deliver the anniversary address next November.

Pott's Disease of the Spine.—Dr. A. M. Phelps read a paper, the full title of which was: "Pott's Disease of the Spine; its Early Symptoms and Diagnosis; Spinal Supports, their History and Growth; Treatment, Surgical and Medical." Cases of so-called Pott's disease were now properly classed under several subdivisions. Orthopœdists now recognized a tubercular form which was slow in development; a form due to acute osteo myelitis in which the onset was sudden; a condition closely resembling Pott's disease, occurring in the course of some fevers, especially typhoid, also that due to actinomycosis.

Pott's disease was a local disease, not constitutional. It started in trauma, light or severe, which set up local inflammation, and the future character of the disease depended upon the kind of germs which found lodgement in the changed tissue. Reparative inflammation was necessary in all cases where there had been injury; such inflammatory tissue constituted excellent pabulum for the nourishment of germs, so that when streptococci, or tubercular bacilli, or the germs of typhoid fever reached the locality, they set up a disease process which differed according to the nature of the germ. The inflammatory material being necessary to the healing process excited on the outskirts of the disease, was liable to be attacked in turn by the germs, and thus the tubercular or other process extended. Tubercular disease did not produce abscess, but if it should become inoculated with septic germs an abscess would form. He hoped never again to hear the term strumous joint. Struma or scrofula indicated a constitutional condition, not a local affection. As already stated, Pott's disease of the spine was always preceded by some form of injury, say by trauma or embolus, which set up an inflammatory process, and if upon this germs were grafted, one had a tubercular spine, etc.

In speaking of diagnosis, the author laid some stress upon rigidity of muscles, which was present both early and late. Early recognition of the affection was important, as treatment instituted at the beginning prevented deformity and gave much more satisfactory results. While the diagnosis was not difficult to make for one who had seen a few cases, yet unfortunately physicians often treated the little patients for months with the impression that they had disease of the heart or lungs, or, particularly, some gastric or intestinal trouble.

As to prognosis, if the case were tubercular it could be cured, but owing to the fact that the child was strumous, and perhaps had tubercular deposits elsewhere, there was danger of recurrence, or death from pulmonary or meningeal tuberculosis. This accounted for so few cases of tubercular spine living to middle age. Typhoid cases usually recovered. If osteo-myelitis were limited to one or two vertebræ, recovery was likely to take place. Cases of actinomycosis were fatal.

Treatment was Operative, Mechanical, and Medicinal.—Mechanical treatment, in his opinion, should involve extension to relieve pressure, and absolute fixation by apparatus which the friends could not adjust or remove.

The most serious indications for surgical interference were large abscesses and paralysis. Paralysis was usually curable without operation. But when operative interference had become necessary the mortality had been nearly fifty per cent. Dr. Phelps had operated in but two cases. The first patient had had total paraplegia as to motion

and sensation for two years. He removed the fifth and sixth dorsal vertebræ, scraped out a hard caseous mass; pus then freely escaped from about the canal, sensation and motion rapidly returned, and the prospects of ultimate recovery were very favorable, when, about a month after the operation, the patient died of pneumonia. The second case was that of an Italian completely paralyzed below the injury, the canal was full of tubercular material a distance of three or four inches; the arches of three vertebræ were removed; drainage was employed. No benefit followed; incontinence of fæces and urine and the paraplegia continued; the man died on the tenth day, and was better off for it, the author thought. It was well to treat the cases mechanically for a time, say two months, even where the paralysis was marked, and operate then only in case the symptoms due to paralysis were increasing.

Regarding abscesses, Dr. Phelps thought that the sooner they were opened, washed out, and drained, the better.

Spinal Supports.—The next subject which the author discussed was spinal supports, first throwing on the screen drawings of apparatus used between the middle of the fifteenth century and the modern period, the latter being illustrated by apparatus bearing the name of various orthopœdists. All the devices at present used were shown to have been employed in some form before the middle of the nineteenth century. They included the suspension apparatus, jury-mast, spinal braces, spinal jacket, elastic tension, extension in the horizontal position, frame for pressure upon the pelvis, etc. Later, however, Dr. Phelps replied to an inquiry by Dr. Sayre, that plaster of-Paris jacket had not been employed at this early date, or before Dr. Sayre had used it.

Dr. Phelps applied the corset, first of plaster-of Paris, later (during convalescence) of light wood or aluminium, the latter perforated and made to fit perfectly by being moulded over the plaster jacket. In all cases where the disease was above the third or fourth dorsal vertebra he applied the jury mast. He did not attempt, however, to lift the head, but only to keep it pushed back, so that the axis would fall back of the kyphos and prevent pressure upon the anterior portion of the diseased vertebræ by the superincumbent weight. In that way he believed further increase of deformity in the upper dorsal region could be prevented, unless the articular and transverse processes should break down. The plaster jacket was applicable only after the third year. Before that period he placed the little patients at his clinic on an improvised plaster slab.

Nothing New under the Sun.—Dr. L. A. Sayre had been much gratified on listening to the reading of the paper. It again verified the correctness of the adage that there is nothing new under the sun. It seemed that all that modern orthopœdists could claim was the rediscovery and improvement of old methods and principles in treatment. He had supposed, for instance, that the jury-mast was new when he first employed it, but had been shown this evening that he was mistaken. It seemed the plaster-of-Paris jacket had first been used by himself, and Dr. Phelps admitted that it did not appear among his ancient relics.

Dr. Sayre thought it was not creditable to the profession that many cases of spondylitis (which term he preferred to that of Pott's disease) were treated during months for supposed disease of the anterior part of the body—worms, indigestion, etc.—whereas if their true nature were early recognized deformity could be prevented, as had often been demonstrated in his practice. When the child got old enough he put on a plaster-of-Paris jacket, which he preferred to other methods. It was changed only often enough to accommodate it to the child's growth. It should not be varnished, as had been done sometimes to add to its appearance. He exhibited two thick cylinder casts of plaster-of-Paris, with a central opening into which he blew smoke from a pipe. The smoke freely escaped through the pores of the unvarnished cast, while his full lung-power failed to drive it through the cylinder with an outside coating of shellac. For the same reason the leather jacket caused excoriations, and was especially objectionable.

He approved of the brace which Dr. Whitman had attached to his plaster jacket, keeping the shoulders back and encouraging deep breathing. His son, Dr. Reginald H. Sayre, had devised the best apparatus with which he was acquainted for application to infants too young to wear a plaster jacket.

Of recent years Dr. Sayre had begun to doubt whether it was necessary to open all abscesses as soon as they appeared. Formerly he did open them, but he had lately seen a number of cases do as well without it.

Has Sueeess with Adult Cases.—Dr. Virgil P. Gibney thought that if the author would give as much attention to Pott's Disease in adults as in young subjects, and get the patients themselves to take similar care, he would cease to regard the diagnosis as specially bad in these subjects. For many years he, Dr. Gibney, had had an idea that adult cases all went to the bad, but when he came to look upon the condition as one of broken back which should be treated with the plaster splint, and considered how long it required to cure a fractured bone, he soon began to get very satisfactory results. Nothing gave him more pleasure at present than to treat such cases, whether complicated or uncomplicated by abscess. He put on the solid plaster jacket for a year, perhaps changing it once or twice during that time. After a year or eighteen months they could wear a corset of almost any material. Adults got well sooner, according to his experience, than did children, in twelve to eighteen months, and did not relapse.

He was glad Dr. Sayre had learned, even at this late date, that it was not necessary to cut every abscess which he saw.

Dr. A. B. Judson agreed with Dr. Phelps in holding the head back instead of trying to raise it, but he much preferred the Taylor chin-piece to the jury-mast. The brace is a lever making pressure on the projection and counter pressure below at the pelvis, and above at the shoulder or chin. Antero-posterior pressure thus made can be applied continuously day and night, while suspension is intermittent. Suspension is simply a form of traction. In straightening a crooked nail we do not apply traction but lateral force or leverage, just as we support a crooked back. He had no word of criticism for the use of plaster-of-Paris in Pott's disease. There are thousands of patients, all over the world, who would have no support if they did not have, thanks to Dr. Sayre, the plaster-of Paris jacket which, properly applied, is vastly better than no mechanical treatment. But in regard to the steel brace he had this to say: It is light and clean; it leaves the muscles of the trunk generally at liberty; by the use of soft steel and the adjustment of straps and buckles, the pressure may be regulated to a nicety, and the brace may be readily and conveniently adjusted to the growth and changing shape. The skin covering the projection should be watched, and pressure gradually increased till the tolerance of the integument is reached. Beyond this it is impossible to push mechanical support. The lobster and crab have the skeleton on the outside, but in our efforts to supplement the defective human skeleton by an external one of steel, we are baffled by the vulnerable skin. The steel brace enables us safely and comfortably to carry mechanical treatment to its utmost limit. Its disadvantage is that it can be used with satisfaction only by residence in, or frequent resort to, places where skilled workmen and special practitioners are found.

Dr. W. R. Townsend, having incorrectly understood Dr. Phelps to say he would operate in cases of paralysis if there was not recovery inside of two months, stated that this was too soon, for the majority of cases of paralysis recovered without operation, but not so soon as two months. He also queried whether Dr. Phelps did not leave so-called cold abscesses unopened, not including

them among abscesses which contained septic germs and which should, therefore, always be opened.

Dr. R. H. Sayre thought the author had lain too much stress upon rigidity of the spine in diagnosis. It was not sufficiently marked early in the history of some cases to be noticed by one who had not before seen similar cases. He would take middle ground between Dr. Phelps and Dr. Gibney regarding adult cases, and would say they required treatment as long as children. The reason why they had not given as good results was because they had not the time to devote to the treatment. Regarding the jury-mast, while he thought it should exert pressure backward, he also thought it of benefit to make traction upward. As proof that it did lift the head, he said that some of his patients complained when the upward traction was removed, although the head were still thrown back. He then described his apparatus, mentioned by his father, for application to children too young to have the plaster jacket.

Dr. Phelps closed. The jury-mast did not lift by the strap under the jaw so long as the jaw could be dropped or the head raised from it, and most patients would object if it did not permit of one of these acts. The backward pressure was sufficient, provided the jacket acted as an antero-posterior brace as well as jacket. He criticised Dr. Judson's brace. The jacket did not cause atrophy of muscles. In paralysis he said he would operate within two months if there were incontinence of urine and fæces, not that he would operate so soon in all cases of paralysis of motion. As to cold abscesses, filled with dirty tubercular material, the sooner this was let out the better; adult cases did not do as well as children, but he did not mean all died.

Clinical Department.

A CASE OF ACUTE GASTRO-ENTERITIS DUE TO MUSTARD.

By CHARLES E. SIMON, M.D.,

BALTIMORE, MD.

It is stated by Kobert (Lehrbuch der Intoxicationen, 1893), that poisoning from mustard and oil of mustard which are obtained from black mustard, Brassica nigra Koch, from Sarepta mustard, Brassica juncea Hook et Thoms, and from white mustard, Sinapis alba L. ("cruciferæ"), is by no means rare, and has been observed in man and some of the domesticated animals.

While this may be the case in certain European countries, mustard-poisoning in the United States, to judge from the literature that I was able to command, and in which I have been unable to find a single instance recorded, must certainly be regarded as a very exceptional occurrence. It may hence not be out of place to put on record a case of acute gastro-enteritis due to mustard taken with criminal intent.

The patient, a German girl, aged twenty-seven, being engaged to a young Polander, and looking forward to marriage in a few weeks, submitted to intercourse, but shortly after found herself betrayed by her lover. The menses not appearing at the time of the next period she considered herself as pregnant, and with the view of ridding herself of what, of course, she looked upon as a great inconvenience, she took a cupful of mustard-flour stirred into a thin paste with vinegar. The greater part of this was vomited immediately. When I first saw the patient, a few hours later, vomiting had been almost incessant, and continued throughout the greater part of the day (January 16th), and the morning of the 17th. On examination of the vomited material, this was at first found to consist of some remnants of food, much mucus, and containing some bile, but no blood; the reaction was acid, but free hydrochloric acid could not be demonstrated with either Günzburg's or Boas's reagent. The material which was subsequently brought up after much distressing retching, was colored a bright green, due to the presence of biliverdin, and was also devoid of blood and hydrochloric acid, its reaction being neutral.

Shortly after the first attack of vomiting, diarrhœa set in, the stools at first being fecal in character, but a few hours later consisting of pure blood, numbering between twenty and thirty the first twelve hours. Tenesmus did not exist.

At the time when I first saw the patient she complained of agonizing pain, confined to the upper abdominal zone, extending into the back, and most severe in the epigastric and upper umbilical regions. The most careful and delicate attempts at palpation in these areas caused excruciating pains, the patient screaming out aloud. Pressure in the lower zone, however, was well borne and caused no distress. The tongue presented a normal appearance.

An examination of heart and lungs was negative; the mind clear; no twitchings or tremor; the pupils of normal size; the pulse small, numbering 92 beats per minute; the respirations shallow, varying between 50 and 60 per minute; the temperature, 97 8° F.; the face was pinched, and the forehead covered with beads of perspiration; dorsal decubitus with legs extended. From time to time patient would rise in bed to relieve the excessive pain of which she complained in her back. There existed great thirst, and, of course, complete anorexia.

The patient, although closely questioned, denied having taken any drug, and affirmed having not felt well for several days, having suffered with "diarrhœa and indigestion;" later in the day, however, the history given above was obtained.

Turpentine stupes, linseed tea, and small amounts of iced Apollinaris were ordered; morphia was given hypodermically in full doses; white of egg, even in teaspoonful doses, was immediately vomited, and no nourishment was hence given during the first twenty-four hours.

On the evening of January 17th the following note was made: Patient passed a restless night, suffering greatly with pain in the abdomen. During the day, between twenty and thirty stools, consisting of pure, red, liquid blood, were passed; the vomiting ceased after midday, blood having at no time been observed in the ejected material, which was watery, containing a small amount of mucus, bile-stained, and free from hydrochloric acid. Fourteen whites of egg were given in the course of the day and were retained. The entire abdomen is excessively tender to the touch, and spontaneous pain continuous, unless relieved by turpentine stupes and morphia, the former being especially grateful. Starch and laudanum (gtt. xx.–xxx.) enemata were given every four hours, and could be retained from ten to fifteen minutes.

The patient's general condition is worse than on the previous day; the temperature at 11 A.M., 96.8° F., at 5 P.M., 97.2° F. The pulse is small, varying between 90 and 110; respirations are hurried; the face is pallid, the pupils contracted (undoubtedly due to the large amount of opium given); the lips are dry and fissured; the tongue also is dry and covered with a heavy fur.

January 18th, P.M.—Patient had a very fair night, much relief being experienced from the stupes. The pain is less, there is no vomiting; the stools, still numerous in the morning, occurred less frequently in the afternoon, and were microscopically free from blood. Anorexia is still complete, and much thirst complained of. Twenty-four whites of egg were given in the course of the day and retained. Treatment same as above.

January 19th.—The patient is much better; the pain less, although the abdomen to palpation is still very sensitive, especially so in the upper umbilical region. Tongue and lips are again moist and the former covered with a heavy white fur. Pulse, 80 to 90; respiration quiet; temperature normal; twenty-four eggs during the day.

January 20th.—Patient to-day had only two stools, both without blood; there is no spontaneous pain, but still marked tenderness in the upper umbilical region; twenty-four whites of egg during the day and a whiskey-glass full of milk every four hours. Patient has a little appetite, general condition is good.

January 21st.—Patient is sitting up in bed, taking milk and whites of egg alternately every two hours; no stool; no pain; very little tenderness on palpation. General condition much improved. From this date on recovery proceeded uninterruptedly, so that patient was able ten days after the beginning of her illness to resume her duties as a cook. An abortion had not taken place.

A vaginal examination made on the 21st revealed a slightly relaxed outlet; carunculæ myrtiformis very prominent; no tenderness; two fingers could be introduced into the vagina without difficulty; the cervix is large and hard, presenting a small left-sided tear; the external os is not dilated; the uterus is freely movable in axis, body sagging in pelvis, somewhat enlarged; right ovary palpable and freely movable, near uterus, of normal size; left ovary cannot be felt.

The examinations of the patient's urine I here append, the most prominent features being a very pronounced oliguria, a slight degree of albuminuria, and an enormous increase in the amount of uric acid and indican.

Examinations of Urine. January 17th.—Amount of last twenty-four hours, 150 c.c.; dark yellowish brown in color, cloudy, with a heavy sediment of urates; very acid; sp. gr. 1.036; trace of albumin with trichloracetic acid; no reduction of Fehling's solution; indican and uric acid enormously increased; large amount of uroerythrin; no diazo reaction.

January 17th, P.M.—Amount of last twelve hours, 180 c.c., of a normal yellow color; cloudy (due to urates); very acid; sp. gr. 1.030; trace of albumin; no reduction of Fehling's solution; indican not increased; uric acid still very much increased, but less than in previous specimen; uroerythrin much increased; no diazo reaction; no diaceturia.

January 18th, A.M.—Urine dark yellow; light flocculent sediment; clear; very acid; sp. gr. 1.036; no albumin; enormous increase of indican, no reduction of Fehling's solution; uric acid decidedly increased; much indigo-red; no diaceturia.

January 18th, P.M.—Urine light yellow in color, clear, acid; sp. gr. 1.019; no albumin; slight increase in indican; uric acid moderately increased; no reduction of Fehling's solution; no diaceturia.

A few hyaline casts and a slight increase in the number of leucocytes were observed during the first two days.

From the 18th on a slight increase in the uric acid and indican persisted for almost a week, when the urine resumed its normal character. In order to fully appreciate the clinical picture described, it may be well to add a few words regarding some of the chemical properties of mustard.

The three plants above named, each contains a glucoside and an enzyme or ferment, both of which, when individually injected into the subcutaneous tissue in moderate amounts, produce no ill effects and reappear in the urine unaltered. Each ferment, however, will decompose each glucoside in the presence of water, with the formation of an oil of mustard. Myrosin is the term which has been generally applied to each of these three ferments, although their identity has as yet by no means been established. Given in large doses, myrosin, like many other ferments, among which may be mentioned invertin, diastase, emulsin, pepsin, chymosin, papain, and trypsin, display poisonous properties.

The glucoside found in black mustard is identical with that of the Sarepta mustard, and has been termed sinigrin, being potassium myronate, while the glucoside of white mustard is known as sinalbin.

The decomposition of sinigrin and sinalbin by myrosin, above referred to, in the presence of water, is said to take place according to the following formulæ:

$$\underset{\text{Sinigrin.}}{C_{10}H_{19}KNS_2O_{10}} = \underset{\text{Glucose.}}{C_6H_{12}O_6} + \underset{\text{Acid. Pot. Sulphate.}}{KHSO_4} + \underset{\text{Allyl mustard oil.}}{C_3H_5NCS}.$$

and

$$\underset{\text{Sinalbin.}}{C_{30}H_{44}N_2S_2O_{16}} = \underset{\text{Glucose}}{C_6H_{12}O_6} + \underset{\text{Acid Sinap. Sulphate.}}{C_{16}H_{24}NO_5HSO_4} + \underset{\substack{\text{Paraoxy.}\\ \text{Benzyl mustard oil.}}}{C_7H_7ONCS}.$$

The same decompositions may occur even in the absence of myrosin, but more slowly, in the intestinal tract of animals in which a high degree of intestinal putrefaction is taking place, such as the herbivora. Of the two mustard oils thus produced, the physiological action of the allyl oil is the more intense.

Following the ingestion of mustard in the human being in large amounts, a most severe action affecting the gastro intestinal mucous membrane takes place, due to the presence of the two mustard oils set free, the common mustard flour of the household consisting of both Brassica nigra and Sinapis alba, manifesting itself in vomiting, salivation, severe enteralgia, colic, diarrhœa, contractions of the uterus, leading at times to abortion, albuminuria, and even hæmaturia, dyspnœa, œdema of the lungs, convulsions, a pronounced depression of the temperature, central paralysis, and even death. Post-mortem inflammatory anatomical alterations are found at the places of contact, as also multiple hemorrhages. The urine is said to emit the odor of oil of mustard, a point which I have not been able to observe in my own case, however; a similar odor is said to be observed in the cadaver. A reducing substance is also mentioned as occurring in the urine, which I have also not been able to demonstrate.

P. S.—On February 24th I was again called to see the patient and found her suffering with intense headache, anorexia, and a temperature of 103.6° F. A careful examination of the entire body proved negative, a vaginal examination being not made at the time however. Antipyrin was given in gr. xv. doses to relieve the headache.

During the night the patient aborted. As an explanation, the patient stated that "she had fallen down the cellar-stairs a few days before;" there is some foundation for the belief, however, that the girl had been in the hands of some abortionist. Recovery. According to the calculations of Professor Mall, of the Johns Hopkins University, who very kindly undertook the examination of the embryo, the abortion took place on the forty-seventh day.

REMOVAL OF A PESSARY FROM THE DILATED CERVICAL CANAL OF A SEVENTY-YEAR-OLD WOMAN.

By HENRY HEIMAN, M.D.,
NEW YORK.
PHYSICIAN TO MT. SINAI HOSPITAL DISPENSARY, DEPARTMENT DISEASES OF CHILDREN.

Mrs. Z——, a German woman, seventy years of age, came to my office on January 15, 1894, complaining of what seemed an attack of uterine colic. Fifteen years before a physician had ordered a "rubber ring" to be worn for prolapsus uteri. A few years later this was discarded for a Zwank's hysterophore, which afforded her great comfort until about three years ago, when it broke. A Hodge's pessary was then advised by another physician, who, however, contented himself with verbal instructions to the patient, never once introducing the instrument himself. About four weeks ago, my patient, in lifting another person, suddenly felt a severe pain in the hypogastric region. She at once examined herself, and failed to find the pessary. Alarmed at this circumstance she allowed another woman to examine her, but the search was futile. Her pain increased, and she finally came to me. Digital examination revealed a greatly elongated and hypertrophied cervix, presenting at the vulva. When the woman strained the cervix even

protruded. Exploration of the vagina gave negative information, I then introduced my index-finger into the cervical canal, and at once detected the missing pessary. Extraction with the bent finger failed. Having dilated the os, so as to admit two finger tips, I passed a stout muslin bandage through the pessary, the small end of which was presenting. Two fingers of my left hand made counter-extension against the os, so that in the extraction a further prolapse should be avoided. Strong traction on the bandage caused the pessary further to dilate the canal, and the removal of the instrument was easy. Very slight bleeding accompanied this operation. Recovery was rapid and uneventful.

220 East 116th Street.

Therapeutic Hints.

Test of flour for diabetics. A weighed quantity of the flour is taken and the carbo-hydrates converted into glucose by treating it with sulphuric acid in an inverted condenser for a few hours, and then estimating the amount of glucose by the alkaline copper test. This process with care gives absolutely reliable evidence.—*Lancet.*

Dangerous "diabetic flours" containing as high as sixty-six per cent. of starch, and yielding the same amount of glucose as wheaten flours, are to be found in the market.

Tonsillitis.—

℞. Ol. eucalyptus glob. ..... ℥ xv.
Spt. camphor..... ʒ jss.
Tinct. guaiac..... ʒ iijss.
Glycerin. ..... q. s. ad ʒ j.

Ten drops on sugar to dissolve in the mouth, every hour or two.
—Miles.

Oil of Cinnamon to abort gonorrhœa. The first day inject one minim to the ounce; the second, two; and thereafter three, made up with a liquid petroleum preparation. Cleanse the canal beforehand with peroxide of hydrogen.—Da Costa.

Neurasthenia —

℞. Tr. kola,
Tr. coca .....āā ʒ jss.
Citric acid..... gr. xv.
Arseniate of sodium ..... gr. ¼

M. Sig.—Teaspoonful three times daily.
—*El Siglo Medico.*

Milk boiling increases the quantity of the soluble phosphates, this appearing to show that the boiled milk contains a larger amount of phosphoric acid already for assimilation.—Crolas.

Calomel is a sure and safe antipyretic, reducing the temperature from two to three degrees in a few hours when given in large dose.—Nunn and Simmons.

Vomiting of Pregnancy. — Horizontal position in darkened room, rectal alimentation. Ice by mouth.
—Horwitz.

When the vomiting is uncontrollable and seriously endangers the patient's life, the induction of abortion or premature labor is indicated, and will, if done in time, to a certainty save the woman.—Blume.

Hemorrhoids.—

℞. Calomel ..... ʒ ss.
Morphine muriate ..... gr. ijss.
Bismuth subnitrate..... ʒ vj.
Vaseline..... ʒ vi.
Glycerine ..... ʒ ij.

Apply.
—Allingham.

Creolin is an agent which in infective pustular eczema effectually controls the process. In scaly eczema it affords marked relief to the irritability and itching.—Patteson.

Tape-worm.—No mid-day nor evening meal. At bed-time thirty grams of castor-oil. The following morning a second dose of fifteen grams of castor-oil. An hour later one gram of salicylic acid, repeated every hour for four doses. If no worm is expelled a third dose of castor-oil.—Ozegovski.

Piperazine is said not to be free from danger in those whose kidneys are unsound.

Vomiting of Gastralgia.

℞. Cocaine ..... .10
Antipyrin..... 1.00
Aq. destil..... .... 90.00

Sig.—A teaspoonful every half-hour to an hour.
—*Canada Lancet.*

In Acute Dysentery, involving the colon high up, I have found large enemata, containing two to three drachms of subnitrate of bismuth, much more efficient than the exhibition of bismuth by the mouth.—Wood.

Cancer of Stomach.—Chlorate of soda, ʒ ij. to ʒ iv., daily.—Brissaud.

Heart Pain.—Belladonna plaster over the organ.

Chronic Bronchitis.—

℞. Tinct. nucis vom..... ʒ j.
Tinct. sanguinariæ..... ʒ j.
Ext. pinus canadensis (dark)..... ʒ iv.
Syr. simp..... ʒ iv.

M. Sig.—A drachm every four hours.

Variola.—Serum, from a man six weeks after variola, was injected (ʒ j. to ʒ ij. into buttocks), and checked progress in a second case.—Auché.

Kava, fluid extract, ʒ ss. to ʒ j., every four hours, controls and cures gonorrhœa in from fifteen to thirty days. —Bacon.

Pichi, fluid extract, ʒ j., every four hours, is especially useful in gonorrhœa and cystitis.—Friedlander.

Methyl-blue, five per cent. solution, to moisten tampons, is said to act directly upon the bacteria in vaginitis, causing discharge and pain to cease.

Toilet Lanoline Emulsion: borax, 1; lanoline, 10; water, 100.

Dentition Fever.—Drop doses of aconite will prevent convulsions. If not, then small doses of bromides.—Hallopeter.

Pilocarpine.—In psoriasis I have met with no good results from the use of pilocarpine, and, in subacute eczema, with bad ones.—Simon.

Hydrochlorate of Quinine, fifteen grains to half an ounce of saturated camphor water for hypodermic use.—Pepper.

Creolin Soap can be employed with advantage in scabies, impetigo contagiosa, intertrigo, as well as in bromidrosis. The lather should be firmly rubbed into the affected parts several times a day.—Carblom.

Acne.—

℞. Camphorated naphthol,
Resorcin,
Salicylic acid.....āā gm. 5
Starch,
Vaseline,
Precipitated sulphur ....āā gm. 25

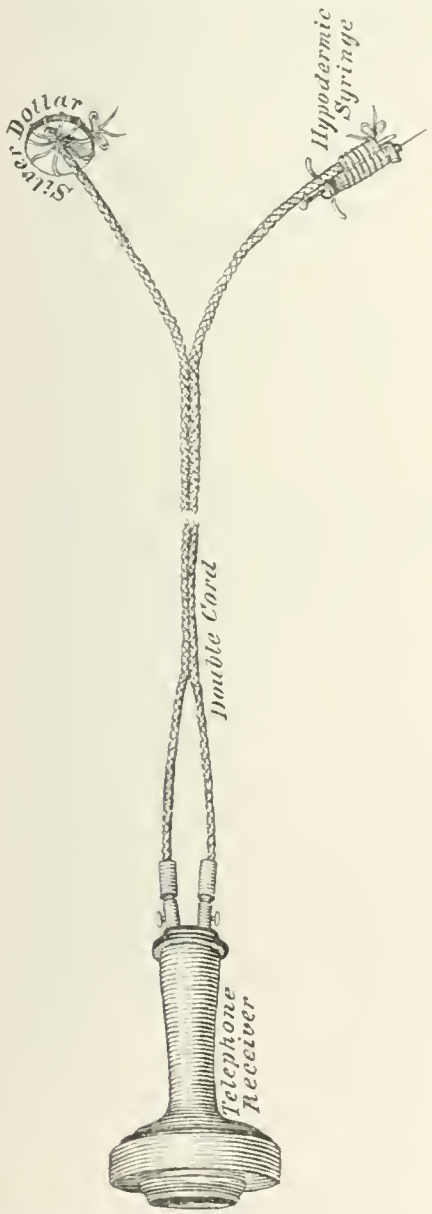
M. et fiat pasta.
—Besnier.

Chronic Catarrh of Stomach.—Large doses of bismuth.—Pick.

Cervical Aneurism.—Macewen's "Needling" should supplement pressure when the case is progressing rapidly; possibly it is advisable in all cases suitable for compression, and is certainly to be employed where this method fails in cases with highly atheromatous vessels.—Nancrede.

New Instruments.

A SIMPLE METHOD OF LOCATING METALLIC BODIES IN THE UPPER AIR-PASSAGES.



By E. N. HEARD, M.D.,

SANDUSKY, O.

ASSISTANT SURGEON, OHIO STATE SOLDIERS' HOME.

In the MEDICAL RECORD, December 16, 1893, page 798, Dr. J. Mount Bleyer described a method of obtaining a lost intubation-tube lodged below the vocal cords. He did this successfully by means of a battery, electric bell, and surgical probe en-circuit, the latter consisting essentially of two needles in a handle, across which closure of the circuit was made by the contact of both needles with the lost body, at the same time. He considers the instrument simple, and indeed it is both simple and ingenious. But the one I wish to offer is much simpler.

Should there be a telephone in the house, take down the receiver or ear-trumpet, together with the attached flexible

cord. To one of the free ends of the bifurcation attach the metallic part of your hypodermic instrument, binding it securely by means of cord. To the other fore end attach a piece of steel of convenient size to be placed in the mouth (the large blade of a pocket-knife might be made to serve). Place the latter in the mouth and see that it is well in contact with the tongue. Then introduce the hypodermic needle through the tracheal wall, the telephone receiver being held to the ear meanwhile. Should the body be touched, even in the slightest degree, there will be a scratching sound in the telephone. The working of this instrument depends upon the well known fact that two metals of different kinds, when in contact with the fluids of the body form a sort of battery which will give current sufficient to influence a telephone receiver. A blunt probe may also be used through the air-passages, a piece of metal of the same kind being connected with the surface of the body, and the telephone. Annexed I give a diagram of the two.

Just here it may be well to say that whatever of plating may be on the syringe, although it does probably make some current with the mouthpiece, yet it makes such a small amount that, being constant in quantity, it makes no practical difference.

Better contact with the skin (in the second instrument) can be made by making the electrode of a silver dollar and moistening it with salt-water, or very dilute sulphuric acid.

The advantages of these instruments over that of Dr. Bleyer are three: 1. Little time is needed to arrange the apparatus. 2. The slightest contact will bring response. 3. There is not the least danger of injury.

In the instrument described by Dr. Bleyer, some ingenuity is needed to arrange the two needles, and both of them must be pressed firmly against the metallic object at the same time.

THE UTEROMETER.

By S. HEMINGWAY, M.D.,

CONSULTING PHYSICIAN TO WORKHOUSE, ALMSHOUSE, AND INCURABLE HOSPITALS, NEW YORK.

THE uterometer is an instrument used to accurately determine the depth and position of the uterus, and to locate and estimate the dimensions of growths therein contained.

Thomas,[1] in his excellent book, speaking of a case wherein he improvised a probe from a corset whalebone with a sealing-wax tip, says, on referring to his whalebone probe: "The sound (*i.e.*, *the probe*) is used in this way—the index-finger of the left hand is placed on the most accessible part of the tumor: then the sound, held in the right hand, is slipped up on one side between the tumor and uterine wall until arrested, when the index of the left hand is placed upon its shaft at the os externum uteri. The sound being then withdrawn, and the finger kept upon it, it is laid upon a sheet of paper or against a blackboard, and being curved, a line is drawn from its tip to the indicating finger. Then the sound is passed on the other side, and a similar transfer of its course is made to the sheet or board."

To Emmet[2] we owe the introduction of the silver probe in gynecology; and with his exceptional skill so many other advances in this line of practice. He condemns the Simpson sound, and his teachings have demonstrated that safety in the uterine examination is in the probe with proper precautions as to cellulitis.

Mundé:[3] "When the probe has reached the fundus, the right index is passed into the vagina, or the dressing forceps grasps the probe at the external os, and thus marks the length of the uterine canal, which must be measured by tape-measure, since the probes are not graduated.

"To measure the depth of the uterine cavity, the index-finger in the vagina is placed along the sound to the external os; the other fingers surround the instrument, which is then withdrawn in the reverse direction from

[1] Thomas: On the Diseases of Women, p. 540. H. C. Lea's Son & Co. 1880.

[2] The Principles and Practice of Gynecology. H. C. Lea. 1879. Minor Surgical Gynecology.

[3] Encyclopædia of Obstetrics and Gynecology. R. Chrobak. Vol. V. Grand, Editors.

which it was inserted, *taking care lest the index finger slip.*" (Italics mine.)

Fritsch, in "Diseases of Women," says: "To this end the tip of the index finger is placed on the sound at the internal (*sic*) os. The finger and sound are removed together, and the measurement is taken."

Other references could be given, but these are sufficient to show the need of an accurate instrument for measuring the depth of the uterine cavity and the attachment of growths contained within it. I fail to find, in any authority on diagnosis and treatment of uterine disease, any instrument fulfilling the properties of the uterometer; and after four years' use of the instrument, it is offered as an additional means of diagnosis.

When one has had a slipping finger or a slipping dressing forceps, and, coupled with either, the difficulty of afterward measuring with the tape-measure, the advantages of the instrument are evident. The whalebone probe has its own, not the uterine curve characteristic of each case.

The extent of attachment of an intrauterine growth is easily found, by first passing the uterometer to the nearest point of touch, and recording the measurement by screwing down the indicator; record this; and with necessary curve pass the instrument or probe into the cavity deeper, and with sufficient curve go to the deeper portion of the attachment, screw down, and the difference between the two measurements will show at once the attachment of the growth in inches or centimetres.

It has been suggested that the instrument is useful in surgical or pathological work to get the depths of sinuses or cavities. The instrument is an aseptic one, can be readily cleansed, is light in weight, and can be easily used, by removing the scale-measuring indicator *B*, as an Emmet probe, *A*.

C. Handle [1] measured in inches and centimetres. Scale indicator *B* will conform to the curve of the probe, and is divided into fractions of inches or centimetres on the handle, can immediately be safely fixed by turning screw-head *D*, to be referred to later if desired, and also with the uterine curve of the case at hand.

I am indebted to Messrs. John Reynders & Co., 303 Fourth Avenue, New York, for their courtesy in preparing the uterometer, and in the interest they have shown in it.

205 East Seventeenth Street, N. Y.

The Effects of Medical Life on the Physician Himself.—In the great majority of cases the special influence of the medical life of the present day is to broaden the views of the man who lives it, to make him independent in judgment; rather sceptical as to the occurrence of the millennium in the near future; quite incredulous as to the truth of the maxim that "all men are born free and equal;" more inclined to consider and perform the immediate evident duty of the day and hour which lies just before him, than to reflections upon the errors of other men; free from morbid fear of death, and of that which comes after death; and none the less a believer in the existence of a Supreme Being and in the fundamental principles of religion, although he may not consider them capable of scientific demonstration.—John S. Billings, in the *International Journal of Ethics*.

A Strong Man on exhibition in London lifts two horses with their riders at the same time, the total weight being about four thousand pounds.

Ibsen was a medical student once.

[1] The handle can be lengthened so that the indicator will reach to tip of probe.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending March 10, 1894.

	Cases.	Deaths.

A Russian Professor's Directions How to Study Medicine.—The following curious letter has been sent to the *New York Times* by a New York correspondent, who has translated it from the Russian. The address is the inaugural of the new Russian director of the Clinic of the University of Dorpat, heretofore an institution of the foremost rank, in which all the chairs were filled by German professors of great learning, and frequented by German-speaking students, mostly inhabitants of the Baltic provinces. By a recent ukase, teaching in the German language has been interdicted; the German professors not willing or able to lend themselves to the destruction of the traditions and usefulness of the university, have been forced to resign, and were replaced by Russian "professors." The inaugural address is literally as follows: "Good Day! Before we take up our activity in clinics, I wish to give you some practical counsel, which, at present, you can only utilize partially, but which will be of great importance to you later when you enter life. Before all, you must be prepared for one thing, that is, as soon as you locate yourselves anywhere as physicians, be it in city or country, you will be chicaned by all the older physicians. But that does not matter, for the moment the public finds this out you get the practice and the older physicians have nothing to do. It happens even that students of the later courses, who practise during vacation, are chicaned by the physicians, because the students prescribe newer medicines of which the physicians have no knowledge. Regarding the relations of your patients toward yourselves, it is self-evident that you must secure for yourselves their esteem. But this you can only obtain if your charges to your patients are high. Ask of every one of your patients ten rubles, not one or a couple of rubles, for otherwise you will be decried as money-squeezers, such as people consider most physicians to be. If you stand on such ground in money matters, the patients will look with respect upon your medical knowledge. If, however, one or the other cannot pay this price, you will rather treat him free of charge, for which he will be attached to you in gratitude. Further, you must impose respect on the public by your conduct. As physicians, you must never get drunk nor loaf in the saloons, and in general must always behave decently, even as students. When I was a student, there studied at the same university seven students who always behaved so properly that everybody said, 'Those must surely be older students,' but they were quite young ones. You must never take more than twelve patients, or you lack conscience, for it is impossible to examine thoroughly more than twelve patients in one day. There are physicians who take over forty patients in one day. They get their hundred rubles, and are satisfied. But if you take twelve patients in accordance with the principles which I have stated to you, you get 120 rubles. When I came here to Dorpat, I found the clinic in bad condition. Thanks to my energetic efforts, it is now in good order, and has been properly cleaned.

And for what did I have all this done? So that you should accustom yourselves from the start to have the clinics clean. Neither is it quite healthy for the patients if they lie about in the dirt. Soon there will be a ukase published commanding the students of the higher courses during vacation into the interior of the empire. There they can learn to speak Russian well, can extend their knowledge, and earn a good piece of money. I shall have to decide who is to get these places. Naturally, I shall appoint those who speak Russian, who visit the clinics, and who are filled with gratitude toward the directors of the clinic."

Surgeons' Hands.—One can tell, nowadays, something of the amount of work which a surgeon does and the thoroughness with which he does it, by looking at his hands. The strong bichloride and permanganate solutions with which the hands are sterilized (after the epithelium has been faithfully scrubbed off with a brush), make the hands rough and horny. The hands of some of the operators and nurses are practically incapacitated for work by this constant *régime*.

A Preliminary Programme of the Congress of American Physicians and Surgeons, to be held in Washington, D. C., has been issued. The meetings will be held on May 29, 30, 31, and June 1, 1894. Dr. A. L. Loomis, President, in the Chair. The programme for the set discussions to be held in the general sessions is as follows:

By the *Association of American Anatomists.*—"Morphology as a Factor in the Study of Disease." Opened with a paper by Dr. Harrison Allen, Professor of Comparative Anatomy in the University of Pennsylvania, and discussed by Dr. Thomas Dwight, Professor of Anatomy in the Harvard Medical School; Dr. Frederic H. Gerrish, Professor of Anatomy in Bowdoin College; Dr. Frank Baker, Professor of Anatomy in the University of Georgetown; and Dr. Burt C. Wilder, Professor of Physiology, Comparative Anatomy, and Zoölogy in Cornell University.

By the *American Climatological Association.*—"Sewer Gas." "The Bacteriology," by Dr. Alexander C. Abbott, First Assistant in the Laboratory of Hygiene, University of Pennsylvania. "As a Cause of Disease," by Dr. Abraham Jacobi, Professor of Diseases of Children in the College of Physicians and Surgeons in New York City.

By the *American Dermatological Association.*—"The Distribution and Control of Leprosy in the United States." "The Distribution." Opened with a paper by Dr. J. Nevins Hyde, Professor of Skin and Venereal Diseases in Rush Medical College, Chicago, and discussed by Dr. William A. Hardaway, Professor of Skin Diseases in the Missouri Medical College, St. Louis, and Dr. James E. Graham, Lecturer on Diseases of the Integumentary System in the Toronto School of Medicine. "The Prophylaxis and Treatment," with a paper by Dr. James C. White, Professor of Dermatology in Harvard Medical School, and discussed by Dr. George H. Fox, Professor on Diseases of the Skin in the College of Physicians and Surgeons of New York City; Surgeon-General W. C. Wyman, U. S. M. H. Service; and Dr. Joseph D. Bryant, Professor of Anatomy and Clinical Surgery, Bellevue Hospital Medical College, New York City.

By the *American Association of Genito-urinary Surgeons.*—"Nephritis in its Surgical Aspects." Opened with a paper by Dr. Edward L. Keyes, of New York City, followed by a paper from Dr. George M. Sternberg, Surgeon General, United States Army; on "The Bacteriology of Nephritis," and discussed by Dr. George Chismore, of San Francisco, Cal.; Dr. L. Bolton Bangs, Surgeon to St. Luke's Hospital, New York City; Dr. Francis S. Watson, Instructor in Genito-urinary Diseases in Harvard Medical School, Boston, Mass.; and Dr. W. N. Wishard, of Indianapolis, Ind.

By the *American Gynecological Society.*—"The Conservative Surgery of the Female Pelvic Organs." Papers will be read by Dr. William M. Polk, Professor of Obstetrics and the Diseases of Women and Children in the University of the City of New York, and Dr. William Goodell, Honorary Professor of Gynecology in the University of Pennsylvania.

By the *American Laryngological Association.*—"The Surgery of the Accessory Sinuses of the Nose." To be discussed by Dr. J. Solis-Cohen, Professor of Laryngology, Jefferson Medical College, Philadelphia; Dr. F. J. Knight, Professor of Laryngology in Harvard Medical School; Dr. George M. Lefferts, Professor of Laryngology and Diseases of the Throat in the College of Physicians and Surgeons in New York City; Dr. F. H. Bosworth, Professor of Diseases of the Throat in Bellevue Hospital Medical College; Dr. William C. Glasgow, of St. Louis, Mo.; and Dr. E. Fletcher Ingalls, of Chicago, Ill.

By the *American Neurological Association.*—"The Influence of Infectious Processes on the Nervous System." "Pathology and Etiology," by Dr. James J. Putnam, Lecturer on Nervous Diseases in the Harvard Medical School. "The Relation to General Nervous Diseases," by Dr. E. C. Seguin, of New York. "The Relation to Mental Disease," by Dr. Charles K. Mills, Professor of Mental Diseases and of Medical Jurisprudence in the University of Pennsylvania; and "The Therapeutics," by Dr. F. X. Dercum, of Philadelphia.

Note on the Employment of Calcium Chloride as a Hæmostatic.—Saundby, in the *Birmingham Medical Review*, contributes a short note upon this subject, basing his experience upon the experimental report of Professor Wright. The three following cases are therefore of interest: The first of these was a middle-aged woman, with chronic jaundice of six months' duration, believed to be due to an impacted gall-stone. She suffered from pretty free hemorrhage from the rectum, apparently proceeding from some internal piles, but the bleeding was decidedly more than we should have expected from the state of the bowel. Our first efforts were directed to remove the hard fæces which could be felt in the rectum by the use of olive-oil injections, and to keep up a daily action of the bowels by the administration of saline aperients; but as after fifteen days these means failed to check the bleeding, calcium chloride in small doses was administered every four hours, with the satisfactory result that after five days the hemorrhage ceased and did not return. The next case was even more striking, as it was that of an elderly woman, admitted with purpura hemorrhagica—that is to say, she had a purpuric rash over the body and limbs, free bleeding from the gums, and slight hæmaturia. The free use of ergot, gallic acid, and acid infusion of roses not having been followed by any benefit, on the third day after admission she was placed upon small doses of calcium chloride every two hours, after which the bleeding diminished, and five days later had ceased altogether, the patient making a good recovery. In the third case, which was one of phthisical hæmoptysis, calcium chloride was used in combination with other measures, but, in spite of all treatment, a profuse hemorrhage set in which carried off the patient. At the autopsy we found an aneurism of the pulmonary artery projecting into a cavity, a condition which sufficiently explained the futility of our remedies. With respect to dose, it is noteworthy that Professor Wright found, after giving 1 gramme thrice daily for four days, that the coagulability became enormously diminished—*i.e.*, to over one hour—and on certain experiments upon himself he believes this was due to the administration of calcium chloride having been carried too far, for he found that when too large a dose of the salt was added to decalcified blood *in vitro*, coagulability decreased, and on taking 2 grammes of calcium chloride three times a day the coagulability of his blood rose during the first twenty four hours, returned to normal during the second, and in the third fell below normal, so that the best results may be looked for from comparatively small doses. In the author's cases the drug was administered in the form of the liquor calcii chloridi of the new British Pharmacopœia,

which is of the strength of 1 to 5, and the dose employed never exceeded 30 minims, or 6 grains, though in the case of purpura this quantity was given every two hours during the day for some days.

Mastitis Diphtheritica by Infection from Stomatitis Diphtheritica.—Dr. Louis Fischer records in the January number of the *Archives of Pediatrics*, the case of a female nursling, aged seven months, who had two large patches, one on the tip of the tongue and the other on the soft palate. They were irregular in outline with a yellowish-green appearance; temperature in rectum 100⅕° F. at 11 A.M.; pulse, 142; respiration, 39; cervical glands considerably enlarged on both sides. No history of existing infectious disease in the same locality. The diagnosis of the stomatitis ulcerosa was made and a question mark (?) entered after same. The mother was cautioned in regard to the other children and the case carefully watched. He again saw the case two days later and found the child in a much worse condition; temperature in rectum, 4 P.M., was 102⅘° F.; pulse, small, feeble, 160, but quite regular. The examination of the mouth showed an extension of the inflammatory condition of the patches, now involving the uvula and left tonsil. The pharynx showed an abnormal redness, but no membrane was visible. While mentioning isolation the infant's mother asked him to examine her left breast, saying her nipple was "cracked" and painful. She explained this by saying that, owing to the baby's irritability, it moved almost constantly and so "bit" her nipple. The examination showed a large semicircular fissure, whitish in places; the breast painful to touch; glands distended from milk; axillary glands enlarged and tender on palpation. The mother complained of aching in her limbs, a "tired feeling" as she called it; had had chills alternating with fever; her temperature was 99⅘° F. in mouth. While examining the infant's mouth and what appeared to be membrane at the nipple, he inoculated two agar-agar tubes and placed them in the thermostat. After thirty-six hours a distinct growth showed small colonies of both streptococci and bacilli which, on staining with Lœffler's alkaline methylen blue, showed distinct semblance to the Klebs Lœffler bacilli. A culture was made, for his own satisfaction, of the patch from the mouth and from the uvula, and also from the pharynx. By a mishap the last test tube was broken; however, the tube inoculated with the uvula patch and the one from the tongue was distinctly diphtheritic, inasmuch as both contained, in almost pure culture, the characteristic Klebs-Lœffler bacilli.

German Literature a French Necessity.—Just at present there is much agitation in France for reform of instruction and examination in medicine. The Ministry of Instruction propounded quite recently certain questions in this direction to be decided upon by the Medical Faculty of Paris. A commission of five professors and the Rector of the Faculty have considered these questions, the principal of which was whether the study of the classical languages should be abandoned? The commission in its answer said: The physician is obliged to use a terminology which is derived from the Greek and the Latin. Although he may, without having been instructed in the classics, in the course of time acquire a superficial knowledge of the expressions, still there will remain in such a case a sentiment of inferiority, because he does not know their origin. In the interest of the dignity of the profession this sentiment should be spared to the future physician. The commission further said, it would be absolutely necessary that in addition to the knowledge of the classical idioms the knowledge of one of the modern languages should be required, namely, the German. In the present condition of the medical science, which derives its elements from all parts of the world, every physician ought to be somewhat of a polyglot.

The above paragraph appears in the *Deutsche Medicinische Wochenschrift*, 1894, No. 5. It is most gratifying to the Germans to learn that the Medical Faculty of Paris thinks the German medical literature of such importance. It will interest also the many American physicians who have learned German for the mere purpose of reading German medical publications.

A Healthy Locality—Dr. Edwin Barnes, of Pleasant Valley, New York, sends us a letter which describes the healthfulness of that part of the State in which he resides. His practice covers the towns of Clinton, Hyde Park, Rhinebeck, Pleasant Valley, Milan, Stamford, and Washington. This region is an almost exclusively farming community; people of limited means, and hard workers. The country is mostly hilly and rugged, with a full proportion of rock, slate, blue trap, and limestone. The valleys are narrow and gravelly, with a rapid fall for the water-courses. The supply of water is almost wholly from shallow wells or springs. In the dry season of August and September water is sometimes very scarce, both for families and stock, but he has never been able to trace any sickness to such scarcity. The whole number of patients treated would be very difficult to ascertain, but there were enough to keep one busy every day and more than half the night. Out of 27 deaths occurring during the above-mentioned time, there was not a single one from a contagious disease in the ordinary sense of the term. There was also a singular freedom from zymotic disease, unless grippe should be thus classed. By taking the age of each patient at nearest birthday, adding all together and dividing by 27 the whole number of deaths, there was shown the surprising average of 60$\frac{19}{27}$ years. One case came from the tenement-house region of New York City five years ago, and was at the time of her marriage suffering from incipient phthisis. Her whole life was one of sickness and privation. Both her children were feeble at birth and died in infancy from marasmus. With these three cases eliminated the average would be 67$\frac{1}{6}$, but it is sufficiently noteworthy to leave it as it is.

THE DIETETIC TREATMENT OF PHTHISIS.[1]

BY HENRY P. LOOMIS, M.D.,

NEW YORK.

GIVEN a case of pulmonary tuberculosis—what weapons at the present time has the medical man at hand with which to combat this disease? Climate, food, and medication. Of these, all things being equal, judicious feeding is the most potent. Climate avails little, when the patient is daily losing ground because of unassimilated food, or food failing to supply the highest possible degree of nutrition. The best health-resort may poorly compensate for the unhealthful cooking of its hotel or boarding-house. Medication may be worse than useless because of an enfeebled digestion constantly disturbed by unsuitable food. Especially in the case of cough mixtures, positive harm may be done by destroying appetite.

In all cases for the successful treatment of phthisis, attention to diet is of paramount importance; climate and medicine being secondary. It is particularly necessary to emphasize this, as it is a point often overlooked altogether, or is noticed with direction so desultory and imperfectly understood by the patient, as to nullify the best results.

It is a well-recognized fact in phthisis that, as the patient's weight increases the symptoms ameliorate, and the physical signs in the lungs improve. We have not only to provide the patients with food for current needs and to repair daily excess of combustion, but to make up, as far as possible, for previous unrepaired waste. It is known that, by care and strict observance of certain necessary regulations with regard to its quantity, its quality, and its methods of cooking and taking, consumptives can be made to assimilate a quantity of nutritive food far in excess of the needs of the organism. We say, then, increase in weight in phthisical patients, with the attendant good results, is brought about chiefly by forced feeding, in many cases without the aid of medication.

1st. In the encounter we meet with feeble digestive and assimilative powers, always with the metabolism of the carbo-hydrates imperfect; so the first thing to be borne in mind is that, to carry out this forced feeding, only certain and distinct kinds of food can be taken—these only at regular intervals and in given quantities.

2d. What may this food be? Milk and meat are the two articles of food which in themselves furnish the greatest amount of heat- and force producing elements with the least expenditure of digestive energy. That milk and meat may be taken in sufficient quantity and during a long-enough period to produce good results, they must be modified and varied to suit the individual case. Here is where the intelligence and care of the physician are put to the test.

A few general rules on the wise administration of these two important articles of diet, in the treatment of phthisis, may be of service.

Milk should never be taken in quantities exceeding eight ounces at a time, and then should be swallowed slowly during ten or fifteen minutes. When several quarts are drunk in twenty-four hours, lime-water must be added in the proportion of a tablespoonful to eight ounces. One of the most palatable ways in which milk can be administered is scalded with seltzer-water added. This mixture is especially refreshing in the early morning.

Some patients cannot take milk, either from a personal idiosyncrasy or enfeebled digestive powers. To such persons kumyss or matzoon can be given with great benefit.

Where the digestive powers are especially weak, peptonized milk can often be assimilated in large quantities, but the objection to its prolonged use is, that after a time its taste palls upon appetite. Two to four quarts of milk should be taken in twenty four hours. The manner of serving it is not unimportant. To some it is more palatable cold, to others hot. In the majority of cases it should be taken slightly warmed (100° F.).

When the different methods I have indicated all fail, then attention must be given to the gastro intestinal mucous membrane. Potations of hot water (aerated in some cases), from half a pint to a pint one hour before meals, must be tried. If this also fails, disinfection of the alimentary canal is indicated, and for this creosote is one of the best agents we have.

Meat can be given cooked rare, or better still, when large quantities are to be taken, in the form of squeezed beef-juice. To obtain from the meat the maximum amount of juice, a meat-squeezer is absolutely essential. There are a number of good ones in the market, which range in price from one to three dollars. The best kind of meat from which to squeeze the juice is a thick round steak free from fat. This should be seasoned with pepper and salt, broiled over a brisk fire, then cut in pieces two inches square, and then put into the meat squeezer. About eight ounces of juice can be obtained from each pound of meat. No heat can be applied to the juice, as the albumin would be at once coagulated and the juice rendered worse than useless. If the juice becomes cold and it is advisable to heat it, this can be best accomplished by placing cup in hot water. It is necessary to go fully into the preparation of the beef juice, because of its importance as one of the most essential items in the diet of phthisis. Freshly squeezed beef juice is the best of the artificial preparations of meat known, and the trouble of preparing it is well repaid by the marked improvement in the patient. Beef tea should never be given in phthisis as an article of diet. The popular idea that it is nourishing is erroneous. Another nutritive and palatable method of preparing meat is in the form of scraped meat balls. The pulp is scraped from a round steak, either by a fork or by a meat-scraper. This leaves the fibrous material behind. The scraped meat is rolled into small balls and broiled over a quick fire, and served hot with pepper and salt, or Worcestershire sauce.

Scraped meat may also be given raw, spread between thin layers of bread. To some this is a very appetizing method. Many of the meat powders on the market, prepared specially for forced feeding, furnish us valuable aid—a preparation from which I have seen marked benefit is the beef peptonoids. Also an excellent meat powder can be prepared in the kitchen, by cutting boiled beef into fine pieces, drying by means of a water bath, and grinding in a coffee mill with the teeth set closely. The methods of administering these meat powders can be varied almost indefinitely. The powders can be added to soups, broths, milk-punch, milk, and may be taken in cold or warm water. The object in preparing the meat

[1] Read before the Association of the Bellevue Hospital Alumni.

in the various ways suggested, is to give the largest amount of albuminoids in the smallest compass, in the most palatable form, and in a way that will not disturb the stomach. I have known cases of phthisis to live for months on nothing but milk and meat prepared as above, and gain steadily in flesh and strength.

Next in order to meat and milk as foods, come stimulants and cod-liver oil.

It can scarcely be questioned that in consumption alcohol is beneficial. Some attribute to it distinct curative power, and would recommend it in all stages. In my opinion it is one of those remedies which is capable of doing good, if judiciously used, while at the same time it is quite as liable to do positive harm. It should never be used in the first stage; in the second stage only in small quantities with food, and preferably in the form of milk punch in the forenoon and on retiring. In the third stage is where it appears to do the most good, when taken in small quantities and repeated at regular intervals. In many cases, in all three stages, a glass of ale or porter twice a day with the meals improves the appetite, aids the assimilation of food, and causes marked increase in weight. For prudential reasons, often it is advisable to disguise the alcohol when given for any length of time. The combination of alcohol with milk, malt, cod-liver oil, or glycerine, is theoretically, as practically, more advantageous than its separate ingestion.

It is well known that muscle-fibre is a loose combination of albumin and fat, and that fat is a component factor in all muscular histogenesis. So in phthisis fat is necessary to the building up of health and tissue, and the dietary should be as rich in fat as the assimilative powers of the patient will allow. The greatest evidence of the value of fat in the food of phthisical patients is furnished by the universal confidence placed in cod-liver oil as a curative agent. It is only the best form of fat because it is the most easily assimilated of all, and can frequently be absorbed when no other fat can be. Nature supplies an oil emulsion in milk, and this largely explains its excellent effects. Cream may be used when it is desirable to introduce fat into the system. It has, however, to be given with care, as in many persons it produces dyspeptic symptoms, which may often be obviated by taking it with a little liquor, as maraschino, or chartreuse, or mixed with aerated water in the proportion of a teaspoonful to a glass.

I am firmly convinced that diet is one of the most important elements we have in the prophylaxis of phthisis. Persons with phthisical tendencies should be properly fed from infancy, and when growing up should be made to comprehend how, humanly speaking, they carry their lives in their hands, and that most often their food inclinations are not in harmony with their tissue needs.

All consumptives pass through three distinct stages in regard to their digestive powers: 1. The period during which digestion and appetite are unaffected. 2. The period from the time when gastric disturbance first begins until the stomach refuses solid food. During this time septic infection is more or less constant, the fever intermittent, and loss of flesh generally progressive. 3. The period from the time when solid food can no longer be taken without digestive disturbances until the death of the patient.

These digestive stages do not necessarily correspond to the recognized physical stages of the disease, but as the diet of these stages varies it is practical to divide the disease in this way.

First Stage.—As soon as the disease is diagnosed systematic dieting is commenced. This is often overlooked, although of such paramount importance. The digestive powers are normal, why limit the diet? some might ask. The object in the early stage of phthisis is, as quickly as possible, to carry the amount of nutriment, and with it the resisting powers of the patient, up to the highest point. This cannot be done by means of the ordinary three meals a day, forced feeding is absolutely essential. Well-defined rules as to diet should be laid down and rigidly adhered to.

Albuminoids and carbo hydrates should form the basis of the three principal meals. Meat should be eaten rare and with all meals. If the patient is over thirty years old, a large amount of meat is essential and can be more easily taken. Two pounds of beef, at least, should be eaten in the twenty four hours, or its equivalent in beef-juice. If poultry is served, the dark meat is preferable to the white. Sweetbreads are often tempting, and may assist digestion. Soft-boiled eggs for breakfast are advisable. A raw egg sucked from the shell will often relieve an irritable condition of the pharynx. Butter should be freely used. Cream on cereals, or diluted with seltzer-water, is of benefit in certain cases.

Milk should constitute the principal drink, and should be ordered between each meal, also a glass or more with the meals. In this way from two to three quarts can be taken in the twenty four hours. To avoid monotony the articles of diet, such as vegetables, etc., ordinarily taken with meals, should not be restricted: except that all indigestible articles, as rich pastries and sweets, should be avoided. The starchy and farinaceous foods should be taken sparingly. While the diet is largely nitrogenous, a sufficient proportion of carbo-hydrates must enter into it. Fats and oils, especially from the animal kingdom, will furnish this. Butter should be freely used.

Cod-liver oil, which is really not a medicine, but a food, should be taken in ℥ss. doses after each meal. Whether directly after the meal, or after a half-hour interval, must be decided according to the personal idiosyncrasies of the patient. When it is impossible to give the pure oil on account of its taste, or because it causes indigestion or eructation, it is wise to give an emulsion of cod-liver oil, pepsin, and quinine, which can be readily taken by almost anyone. Often the pure oil can be taken when floated on whiskey. During its first stage the phosphates are valuable, and it is advisable to give food which, owing to the presence of phosphates, is desirable. However, it must be remembered that to supply the phosphates in sufficient quantities, special preparations must be made use of. The hypophosphites should be given after meals diluted in water. In certain cases they are even more valuable than cod liver oil.

Second Stage.—This is the period which will most try the physician's patience, and is the one in which systematic diet is absolutely essential. The relief from coughing, fever, and digestive disturbances experienced by this class of patients in following the dietetic regimen prescribed, is of great help to the physician, as a guarantee that his directions will be implicitly followed.

In this stage the diet varies rather in the methods of preparing the food than in the food itself. The patient is still fed six times a day, but the meals are restricted. All foods should be offered in the most palatable form and generally given finely subdivided. This is the stage when beef-juice and scraped beef are specially indicated. A small glass of the former in the middle of the forenoon and afternoon, with a cracker and a scraped meat-ball or raw meat sandwich for lunch or dinner, will materially aid nutrition. In many cases, a glass of porter or ale with lunch or dinner, will be of a great benefit in increasing appetite and adding flesh.

Milk plain with lime-water, or boiled, should be given early in the morning, at bed-time, and between meals; but I have learned by experience that this should never be taken at the same time with beef-juice. When milk disagrees with patients kumyss should be substituted, to the amount of three or four bottles a day. With the exception of the malt liquors with meals, stimulants during this stage are apt to do more harm than good. Cough mixtures should never be taken, if they can possibly be avoided. The syrups and narcotics which they contain are almost certain to produce digestive disturbances, in spite of the most rigid dieting. Cod-liver oil will be required, but the greatest care must be used in its administration. The emulsion spoken of in the first stage will

often be assimilated without any trouble. Especially in patients in middle life, the pure oil with whiskey will give the best results. Other cases can take cod-liver oil in capsules. Still others, can only take the oil in the mixture known as hydroleine. I feel so sure of the great benefit derived from cod-liver oil in this stage, that all known methods of administering it should be tried before it is abandoned. The duty of the physician who regulates the diet of phthisis does not end there. He must watch the condition of the stomach and intestines, that they may welcome and absorb the nutritive food furnished so often. Especially in this stage, he must make use of digestive ferments to aid assimilation, such as pepsin before and hydrochloric acid or pancreatine after meals. In this way the patient may be enabled to digest an amount of food liable, under ordinary circumstances, to cause dyspepsia. In cases of a catarrhal condition of the intestines the systematic drinking of a half to a pint of hot water before meals will prove beneficial. It is especially important that the condition of the bowels be watched, and if possible a daily evacuation obtained.

Third Stage.—As persons who have reached this stage are generally hopeless cases, all that we can expect by diet is to prolong life under the most comfortable circumstances; much of the distressing coughing and vomiting from which these patients suffer can be controlled by attention to the quantity and kind of food. It is well to give up the idea of three hearty meals a day, and for a time, at least, feed the patient every two hours in small quantities. This is the time when the artificially digested preparations, such as the beef peptonoids, do so much good. Milk with lime-water can be alternated with them with advantage; often it is necessary to peptonize the milk, and sometimes it has to be given up entirely. Stimulants often repeated, say once in four hours, and in small quantities, generally help this class of cases a great deal. Stimulation and feeding should be kept up regularly during the night, when the patient is awake. Equal parts of porter and lime-water are generally well taken and are often of great benefit. It is a well-known clinical experience, that patients in the last stages of phthisis have times of perfect freedom from any digestive disturbances; they can apparently digest almost anything without trouble. When these times come it is advisable not to restrict their diet, but to allow them anything they crave, remembering that on the least indication of dyspeptic trouble the restricted diet must be resumed. Fresh fruit in this class of cases ordinarily does no harm and is very refreshing. In those cases where the taking of food into the stomach is almost sure to excite paroxysms of coughing which induce retching and vomiting, it is advisable to stop all food and commence artificial feeding through the soft stomach tube. I cannot agree with some, that feeding through a stomach-tube is applicable to most cases. The natural repugnance which persons have to its use must limit its application to exceptional cases, to those whose physical or psychical disability prevents superalimentation by less distressing methods. Where it can be used the person can be made to digest and assimilate more food than he would be willing to, or could swallow; the patient is, as it were, stuffed to his utmost capacity. Credit should be given to Debove, who introduced this method and demonstrated what is meant by sufficiency of alimentation, namely, the extreme limit of assimilability.

Some of the most important rules which should govern the dietetic treatment of phthisis may be formulated as follows: 1. Never take cough mixtures if they can possibly be avoided. 2. Food should be taken at least six times in the twenty-four hours; light luncheons between the meals and on retiring. 3. Never eat when suffering from bodily or mental fatigue or nervous excitement. 4. Take a nap, or at least, lie down for twenty minutes, before the mid-day and evening meals. 5. Take only a small amount of fluid with the meals. 6. The starches and sugars should be avoided, as also all indigestible articles of diet. 7. As far as possible, each meal should consist of articles requiring about the same time to digest. 8. Only eat as much as can be easily and fully digested in the time allowed. 9. As long as possible, systematic exercise should be taken to favor assimilation and excretion; when this is impossible, massage or passive exercise should be undergone. 10. The food must be nicely prepared and daintily served; made inviting in every way. The following may serve as a sample of a diet sheet in the early stages of phthisis:

On Awakening.—Eight ounces of equal parts of hot milk and seltzer, taken slowly through half an hour.

Breakfast.—Oatmeal or cracked wheat, with a little sugar and an abundance of cream, rare steak, or loin chops with fat; soft-boiled or poached egg, cream toast, half pint of milk, small cup of coffee.

Lunch, 10 A.M.—Half-pint of milk or small tea-cup of squeezed beef-juice with stale bread. 12, noon: Rest or sleep.

Mid-day Meal, 12.30.—Fish, broiled or stewed chicken, scraped meat-ball, stale bread, and plenty of butter, baked apples and cream, two glasses of milk.

Lunch, 4 P.M.—Bottle kumyss, raw scraped-beef sandwich, or goblet of milk. 5.30 P.M.: Rest or sleep.

Dinner, 6 P.M.—Substantial meat or fish soup, rare roast beef or mutton, game, slice stale bread, spinach, cauliflower, fresh vegetables in season (sparingly)

THE SELECTION AND PHYSICAL EXAMINATION OF THE RECRUIT.

By CHARLES B. EWING, M.D.,

CAPTAIN AND ASSISTANT SURGEON, UNITED STATES ARMY.

(Continued from page 332.)

THE efficiency of the soldier is dependent as much on the art of marching as it was in earlier times, and Marshal Saxe and General Fay assert that the secret of war lies in the strength of "the legs of the soldier." The rapidity of combinations and the celerity of movements are the best index of the physical efficiency of troops, and we have no better illustration of this than in the armies led by Napoleon the First and well-known leaders of the Federal and Confederate armies during our late unpleasantness.

Inasmuch as the growth of the skeleton preserves a distinct and definite order, it will not be out of place to sketch it hastily during the so-called "military age," from sixteen to thirty years, as shown by our best anatomists—Allen, Thomson, Turner, Ellis, and others:

"The epiphyses of the transverse and spinous processes of the vertebræ hardly commence to ossify before sixteen years of age, and it is not till after twenty years that the two thin circular plates form on the bodies of the vertebræ. The whole process is not completed till near the thirtieth year. The sacrum only commences to consolidate at the eighteenth, and is completed from the twenty-fifth to the thirtieth year. The fourth and third bones of the sternum are only united between the twentieth and twenty-fifth years, and the second is not united to the third bone before the thirty-fifth year. The epiphyses of the ribs commence to grow between the sixteenth and twentieth, and are completed by the twenty-fifth year. The epiphyses of the scapula join between the ages of twenty-two and twenty-five. The epiphysis of the clavicle begins to form between the ages of eighteen and twenty years. The internal condyle of the humerus unites at eighteen, but the upper epiphysis does not join till the twentieth year. The epiphyses of the radius and ulna, the femur, the tibia, and fibula, are all unjoined at eighteen years, and not completely joined till the twenty-fifth year. The epiphyses of the pelvic bones (crest of ilium, spine, and tuberosity of ischium) begin to form at puberty and are completed by the twenty-fifth year." Hence, from the standpoint of developmental anatomy we must conclude that the soldier should not be enlisted before twenty. If, however, at an earlier age, his immaturity must be

recognized and his training be proportionate to his growth. This is especially true when the effect of pressure upon the growing chest and contained organs is considered in connection with the weight of equipment. In moulding bones one of the chief elements in determining shape is *pressure*. It is admitted by all that the chest does not reach mature growth till thirty. This being true, any continued pressure from before or behind must materially influence its form while growing; especially is this the case at the present time, as the mode of carrying the greater part of the equipment is very unsatisfactory. Many devices have been invented in foreign armies by which the pack is to be carried. These packs are not unlike, in size and shape, the knapsacks carried during the late war. The weight to be carried in our service, minus the armament, is the aggregate of the contents of the blanket bag, haversack, and full canteen, amounting to about fifty pounds. The blanket bag is carried by shoulder-straps, and the haversack and canteen hang pendent from the shoulders.

The growth of the chest, we have seen, is not completed till thirty years, that of the heart is still going on at twenty-five, and the lungs have not reached their maximum weight till thirty years of age. It is very evident then, from this, that the question of carrying the equipment is only next in importance to selecting the soldier. All nations except England err in having the pack suspended on the upper part of the back by means of straps which pass under the arms and over the shoulder. The result is very easy to guess, as two of the "vital tripod," the lungs and heart, become embarrassed by pressure of the straps upon the front, and the pack upon the rear, of the chest. That the principle underlying this is wrong is quite clear, as the weight of the pack should be really thrown upon the loins, or that portion of the back just above the buttocks. With this method the least pressure possible is exerted by the straps of the back upon the front chest. How to do this and at the same time have a simple apparatus, which can be easily put on or off, is a difficult problem. Colonel Merriam, of our service, devised a most excellent pack, the weight being thrown principally upon the loins, but this equipment is so intricate that it almost destroys its usefulness. The English have the pack suspended on a level with the loins by two shoulder straps, which are fastened to the waist-belt in front. Two additional straps pass under the arms from the knapsack to the straps in front of the body. On the waist-belt in this situation are two full cartridge-boxes, which to a certain extent offset the load behind. Much fame awaits the man who shall give to us a simple, easy, comfortable pack.

Maximum Age.—This varies in our service and is governed by the Adjutant-General. At the present time it is thirty for all arms, although a short time since this only obtained for the cavalry, thirty-five being that for the other arms. My suggestions relative to this are mentioned later.

Height.—The minimum limit of stature has varied so materially with us since the formation of our army, that it is deserving of special notice. The object aimed at in prescribing this lowest limit has been to exclude such as lack the physical strength necessary to endure the hardships of a soldier's life. These changes have sometimes been brought about by regulations, and at other times by law. The act of April 30, 1790, fixed the minimum stature at 5 feet 6 inches, and this standard was also recognized by act of March 3, 1795. The act of July 16, 1796, however, left this to be determined by the President, which remained unchanged by the acts of 1798 and 1799, during the war with France. The old standard of 5 feet 6 inches was again returned to by the act of March 16, 1802, but during the war of 1812 no limit was fixed, as all "effective men" were taken. No further modification was made till 1825, when by Army Regulations the height of 5 feet 6 inches and 5 feet 8 inches were fixed for the infantry and artillery, respectively; these obtained till 1838, when 5 feet was made the minimum for all arms of the service. Army Regulations of 1841 increased this 5 inches. This held till the Mexican war, when it fell to 5 feet 4 inches, and finally to 5 feet 3 inches, by Circular A. G., November 18, 1846. Eleven years elapsed without variation, when, in 1857, an addition of 1½ inch made it 5 feet 4½ inches. The breaking out of our civil war caused a return to what it had been in 1846, 5 feet 3 inches, and this was further reduced by the exigencies of the rebellion to 5 feet, in 1864. This diminutive stature held good till February of 1867, when it became 5 feet 5 inches by Circular A G.O.; but this was reduced 3 inches in May, and remained so till December 2d, when a return was made to what it had been in the early part of that year. The War Department Circulars of August 24 and October 18, 1871, specify that the minimum of 5 feet 5 inches shall apply to cavalry and infantry alike. The following year, 1872, a reduction of one inch was made for all branches of the service; this did not last long, for in December it was determined that the cavalry should be governed by what it had been in 1871 for that arm, 5 feet 5 inches. In January of the following year this was changed to 5 feet 6 inches for cavalry, and the succeeding month it likewise applied to infantry and artillery. In December of 1874 a reduction of two inches for infantry and artillery and one for cavalry was made. Only one change has occurred up to the present time, so that the minimum of 5 feet 4 inches for all arms is the fixed standard, exceptions being made in favor of band musicians, school-teachers, and tailors, who may not fall more than one-fourth of an inch below this.

Maximum Height.—No maximum of stature was prescribed in our service till December 23, 1872, when the limit of 5 feet 10 inches was announced for cavalry recruits; that for infantry and artillery being governed by the maximum of weight, to which should be applied the rule for proportion in height according to the various epitomes of Tripler. In considering these physical equivalents of age, an understanding must be arrived at as to the difference between a "mean" and an "average."

Height.—The mean height of the male adult at full growth, compared with mean height at nineteen years of age, in various countries.[1]

Mean Height at 19 Years of Age.	(25 Years.) Mean Height of Adult.	Difference.
Belgian (Quetelet) 5′5″.16=1 655 metre.	5′6″.22=1.682 metre.	1″.06=027 metre.
American, white (J. B. Baxter) 5′7″.07=1.7036 m.	5′8″.22=1.7328 metre	1″.15=0708 m.
Criminal classes (Danson) 5′4″.94	5′6″.30	1″.36
Englishmen (Roberts)—		
Laboring class 5′6″.5	5′6″.5	
Non-laboring 5′8″.75	5′9″	0″.25
English (Beddoe & Amer) 5′6″.577=1.6911 metre.	5′6″.6=1.6934 metre.	0″.32
Scotchmen (Beddoe)	5′7″.5	
Viennese (Liparzik) 5′4″.96	5′8″.90	3″.94
Genoese (Dunant) 1.674 metre.	1.688 metre.	0.014 metre.

(1) From Charles Roberts's "Manual of Anthropometry."

According to Sir John Herschel, "An average may exist of the most different objects, as of the heights of houses in a town, or the sizes of books in a library. It may be convenient to convey a general notion of the things arranged, but an average involves no conception of a natural and recognizable central magnitude, all differences from which ought to be regarded as deviations from a standard. The notion of a mean, upon the other hand, does imply such a conception, standing distinguished from an average by this very feature, namely, the regular march of the groups increasing to a maximum and then diminishing." The study of those individuals whose physical equivalents are above and below the average is the most important to the examining surgeon, because, here agencies are very significant in modifying the development of the body. The mean height is the typical height possessed by men in groups; the average is the aggregate of all the individuals in the groups divided by the entire number forming them. Height is governed by age, sex, race, and

those secondary influences of disease, occupation, habits, and surroundings, nutrition, food, labor, exercise, and rest. A marked difference in height is shown between the laboring or artisan, and the non-laboring or favored classes. Roberts says, that between seventeen and twenty-five years among the former, a difference of two inches is seen, whereas only an inch exists among the latter. The mean annual growth among the laboring class is two inches at seventeen years, and of half an inch between twenty five and thirty. Another important point is that puberty has a very marked influence on growth, for as puberty approaches there is "an increased rate of growth toward height and an entire cessation of it at nineteen or twenty years in the non-laboring; while in the laboring class growth toward height is less influenced by puberty and is more uniform, extending to about the twenty third year. Hence, in the selection of the soldier, it is important to bear in mind that there are certain periods of life at which growth toward height is more or less arrested, and there are also times of growth more or less rapid than others." (Quetelet.) I do not think that the differences of growth in height between the non-laboring and the industrial classes obtain here to the extent they do in England and continental countries, yet they are great enough to warrant close study. M. Boudin demonstrated long ago that "no actual relation between mere stature and aptitude for military service" existed. The late Surgeon-General Baxter, in his medical statistics of the Provost Marshal-General's Bureau, found that the ratio of rejections increases with increase of height. Aitken insists that the "taller the recruit the more important it becomes that he should be tested by the spirometer," inasmuch as the majority of the cases of tuberculosis is found in the tall men. It is extremely difficult to fix a uniform standard of height, as the mean stature is found to vary so much under the influence of race. The minimum, where fixed, should be made to vary with the race. This is well illustrated by the table from Roberts's "Anthropometry," which shows the mean height of the male adult at full growth, compared with the mean height at nineteen years of age, in various countries.

Weight.—Quetelet was the first to determine by the study of a large number (10,000) of individuals of the same nationality, of like age and subjected to the same conditions of environment, that the same uniformity as to weight prevailed that had been found to exist as to stature. The weights were found to range themselves into a curve, the well known binomial curve of Newton. The statistics of weight during the late war were so meagre that they were not worked out, and those collected since, though more accurate, have not been used.

Table of Physical Proportions of Height, Weight, and Chest Measurement. Modified to Correspond to the New Increment of Weight, 1.85 pound.[1]

Height.	Weight.	Chest Measurement.	
Inches.	Pounds.	At Expiration. Inches.	Mobility. Inches.
64	118.40	32½	2
65	120.25	33	2
66	122.10	33½	2
67	123.95	34	2
68	130.80	34	2½
69	137.50	34½	2½
70	144.50	35	2½
71	151.55	35½	2½
72	158.20	35⅞	2½
73	165.05	36¼	3½

[1] By Captain and Assistant Surgeon Chas. B. Ewing, U. S. A.

Our regulations fixed no limit to weight until a few years ago, which, however, remained unchanged till very recently. In 1890 the minimum weight of all recruits was fixed at 128 pounds, except for cavalry, in which no limit was fixed, "provided the chest measurement and chest mobility are satisfactory." The maximum for infantry and artillery is 190 pounds, for cavalry and light artillery 165 pounds.

Table of Physical Proportions of Height, Weight, and Chest Measurements.[1]

Height.		Weight.	Chest Measurement.	
Feet.	Inches.	Pounds.	At Expiration. Inches.	Mobility. Inches.
5.4-12	64	128	32½	2
5.5-12	65	130	33	2
5.6-12	66	132	33½	2
5.7-12	67	134	34	2
5.8-12	68	141	34	2½
5.9-12	69	148	34½	2½
5.10-12	70	155	35	2½
5.11-12	71	162	35½	2½
6.	72	169	35⅞	2½
6.1-12	73	176	36¼	2½

[1] Greenleaf's Epitome of Tripler's Manual, Ed. 1893.

This has been modified so that we find the entire "physical equivalents" that should relate to age changed by a few lines in our present regulation, which says that, "The following rule for proportionate height, weight, and chest measurement is substituted for that on pages 26 to 28 of the Epitome." The rule is: "For each inch of height from 5 feet to 5 feet 7 inches, calculate 1.85 pound of weight; above 5 feet 7 inches, add to this standard 5 pounds for each inch of height; minimum chest measurement at expiration from 5 feet to 5 feet 7 inches, half the height plus half an inch; from 5 feet 7 inches to 5 feet 10 inches, half the height; from 5 feet 10 inches upward, slightly less than half the height; minimum chest mobility, 2 inches."

Upon analysis I cannot quite see wherein the rule mentioned can be a substitute for "proportionate height, weight, and chest measurement," found on pages 26 to 28 of the "Epitome." The decrease in weight averages about 10 pounds to the inch in height from 5 feet 4 inches to 6 feet 1 inch, but the same rule specifically repeats the manner of determining chest-girth previously in force, so that now we have diminished weight proportionate to height, with a very much increased and disproportionate chest girth. The views formerly held by Aitken, Parkes, and others, erroneously however, that the weight in pounds should be about twice the height in inches, has seemed to govern our regulations. This decrease of .15 in the increment of weight, seemingly a trifle, is really an average decrease of ten pounds to each inch from the present standard, as shown in the accompanying table.

Study of this table in comparison with the former, of physical proportions in force up to this time, leads to the conclusion that the standard chest-girth is much too high for the fixed height and weight. That, as it has been found essential to reduce the weight ten pounds to the inch of height, it must of necessity follow, if the relation of chest-girth to the new standard is to be maintained, that it must likewise be reduced. In other words, the physical equivalents, as they relate to age, are not at present true. It is rather difficult to say just how our standard of "physical proportions" was determined. The most important factor, age, has not been taken into consideration, and I have hunted far and wide for light upon this subject. A glance at this table, compiled from data from Baxter's "Work of the Provost Marshal-General's Bureau," shows that the height and chest-girth of all the nationalities differ in their relation to age. The data consist of over half a million accepted recruits, "under the age of twenty" and up to "forty and over." Here we find without exception all showing less chest-girth in relation to height than our present standard. Another very important deduction is that our fixed weight of former regulations, now very materially and sensibly changed, was far in excess of that shown upon actual demonstration by this table, but to be consistent the chest-girth should be diminished proportionately.

Height and Girth of Chest at Expiration in its Relation to Nativity and Age.[1]

Americans (White).	Number Examined.	Mean Height.	Mean Girth of Chest.
All ages	190,621	67 69	33 59
Under 20 years	46,855	66.57	32.24
20 and under 25	52.393	67.82	33.55

40 and over	4.600	66.45	34 40

[1] From Medical Statistics of the Provost Marshal-General's Bureau, Vol. I.

One of the ablest authorities, Charles Roberts, says, "that for each inch in height the weight is increased 4 pounds from ten to fifteen years; 6 pounds from fifteen to sixteen; 8 pounds from sixteen to nineteen, and from nineteen to thirty years of age there are 6 pounds added to the weight, while the height remains stationary." While this may be true for the inhabitants of England, these figures would hardly govern here with our population of mixed nationalities.

Weight.—Weight is the least reliable, however, of all the physical equivalents of age, being influenced more by accidental causes than chest-girth or height. A healthy environment, abundance of food, and good digestion favor an increase of weight. This is particularly noticed in comparing the mean weight of the English laboring and non-laboring classes, where in the former at seventeen years of age you have a mean of 116, as compared with 140 pounds in the latter, and 128 as compared with 148 pounds at nineteen years of age.

Variation of Weight with Age of same Stature.[1]

Stature.	Weight at eighteen.	Weight at nineteen.
Inches.	Pounds.	Pounds.
67	126	136
66	120	130
65	116	121
64	115	120
63	117	117
62	111	113
61	102	119

[1] From Aitken.

The Relation of Weight to Age.—Aitken says, after nine years of age an increase of weight begins, so at sixteen we have an increase of 16 pounds for that year. From seventeen to twenty-three or twenty-four, the rate of increase diminishes till thirty is reached; after thirty adipose is taken on rapidly and weight increases. The late Surgeon-General Baxter, in his work, fixed the increment of weight between 61 and 71 inches of stature at 5.96 pounds. Hutchinson's results show 5.14, and Gould 4.25 pounds, making an average of 5.07 pounds. I have mentioned the erroneous idea that two pounds for every inch of stature constituted a sound body, also that our increment has been changed to 1.85 pound to the inch, with the additional 5 pounds above 5 feet 7 inches. That weight varies with age in youths and men is graphically shown by this table from Aitken.

Chest-girth.—Some difference of opinion exists as to the best manner of obtaining the chest-girth. Tripler contends that the tape should be placed below the nipple in front, which behind would carry it beneath the point where the latissimus dorsi springs from the trunk. He holds that in this way a more exact measurement is made, because you do not include the mammæ, nor the pectorals and latissimus dorsi muscles in your measurement. This has not been thought worthy of adoption, however, so that in our service the tape is passed around the chest over the inferior angles of the scapulæ and directly above the nipples, the tape being pressed evenly. Measurements are to be taken both at expiration and inspiration. Chest mobility is one of the best criterions of endurance and fitness for continued exertion. American statistics of the white natives, by Surgeon-General Baxter, and those of Balfour of the English army, show a regular relation of chest girth to height, though other authorities do not think that this has been definitely determined. The agencies, environment, and occupation have produced marked differences, as observed in the favored or non-laboring and laboring classes of England, by Charles Roberts. The tables are appended and well worth study.

Hutchinson says that three inches is the mean mobility of a healthy chest, and further asserts that "the vital capacity is the same in all men of the same stature." Vital capacity he terms "the most complete voluntary expiration immediately following the most complete inspiration."

Both of these propositions are untrue. As regards the first, I have seen many very healthy men with a less mean than three inches, and as to the second, it would be absurd to say that Sandow, "the Strong Man," with a chest-movement of nine inches, possesses no more vital capacity than other men of his height (5 feet 8 inches) who have only a chest-movement of 2½ or 3 inches. Hutchinson further says that "vital (chest) capacity" increases 8 cubic inches to each inch of stature from five to six feet and, therefore, chest mobility increases and decreases with the height, according to an arithmetical progression. The latter proposition is now held to be true within reasonable limits of error, hence I hope that our chest girth will be reduced to conform to the recent standard of weight given us.

Average Heights, Weights, and Chest-girths, with minimum of latter and annual rate of increase from seventeen to thirty years of age, from public schools, naval and military cadets, medical and university students, i.e., well favored non-laboring classes.[1]

[1] From Charles Roberts, F.R.C.S.

All of these physical equivalents are so important in their relation to age that I suggest that our tables be entirely revised, and that data be obtained from statistics collected by recruiting officers since the war, in which much care has been taken in determining weight, together with the other physical equivalents.

Hemorrhoids.—Our regulations say they "may be recent or old. If recent they will appear about the size of a buck-shot, of a bluish color, hard and tense to the feel, and their covering will look thin. If old they will probably be as large as a marble, of a brawny feel, reddish-brown color, and have a thick covering. If recent, as above described, they are not cause for rejection, neither are they if old and single, and the applicant asserts they have never been painful or troublesome: but if there should be more than one old pile and they are larger than described, or if a single old pile is ulcerated or inflamed, or if there is a small pile associated with varicose veins of the legs, the applicant should be rejected." Thus you see we draw a very fine point on the age and size of piles. Comment here is hardly necessary. If this regulation simply governed the recruiting officer it might be well and good, but it applies equally to the examining surgeon; hence, I believe these gross pathological distinctions should be stricken out, so far at least as they concern the surgeon, permitting him to exercise his judgment and knowledge of morbid conditions. I know of many good men rejected by reasons of this peculiarly worded paragraph.

Varicocele.—This is so much the bane of the depot surgeon's existence that I cannot pass it by without a few words. The regulation says "the rule formulated by Tripler, which if strictly followed will exclude from the service men thus physically unfitted." The rule is as follows: "If the testicle upon that side is atrophied (shrunken), whatever may be the volume of the cirsocele (varicocele), or if the volume of the latter exceeds that of the former, the recruit should be rejected; that is, the varicocele should not be greater in bulk than the sound testicle." Such a large number of recruits are rejected annually for varicocele that this is deserving of special consideration. This antique dictum has resulted in so much injury to the service that I cannot forbear comment. No other service in the world has such a regulation as this, where the examining surgeon turns himself into a pair of scales, balancing a testicle in one hand and a collection of varicose veins in the other, hoping to determine their respective size and weight, which to say the least is a method unscientific and unbecoming. Much stress has been laid upon atrophy of the testicles, as if varicocele was the only cause of that condition. This is rather absurd, as it is well known that excessive venereal indulgence or masturbation will cause atrophy. In fact, any cause which causes pressure on the spermatic cord, thus influencing the nerve supply to these organs, will produce atrophy. I have seen the continuous use of a suspensory bandage do this, and it is well known that it arises from paraplegia, injuries of the spine and cranium, and orchitis from injury or mumps. Professor Halstead, of Johns Hopkins, agrees with me in believing it not infrequently due to chronic gonorrhœa, where the inflammation has extended to the testes, destroying the function of those cells necessary to growth of the organ. Again, what if the testicle is atrophied? A soldier is not enlisted because of his procreative power, and I have failed to find a single instance where a diminution in size of the testicle has caused loss of strength or stamina in him.

Surgeons Henderson and Marshal, both of large experience at home and abroad, have never seen a man report sick from this cause. Assistant Surgeon Coolidge says, "some degree of cirsocele is very common, and if men are to be rejected for this affection indiscriminately, our rendezvous might almost as well be closed." Humphrey says that this condition occurs once in every ten males. Of 166,317 recruits inspected in Great Britain and Ireland during ten years, 55,474 were rejected, and 3,911, or 70.5 per 1,000, for varicocele. Of 2,165,470 recruits examined in France, for a period of ten years, 20,553, or 10.05 per 1,000, were exempted for varicocele. Durind the late war there were recorded 7,276 cases of varicocele, but then we must consider the very large number of men in the field of various sizes, ages, and conditions. It is generally admitted that very few cases of varicocele require operative interference, and when performed it is not so often to relieve the pathological conditions as it is to minister to a diseased imagination. In my twelve and one half years' experience in the service I have only seen a single case of varicocele upon sick report. I think this condition more common than we have been led to suppose, and we would enlist very few, if held to the strict meaning of the term.

Enlistments and Rejections.—For the past five years

enlistments have been made, at rendezvouses of the general and mounted services, as follows:

Fiscal year ended June 30, 1889	6,637
Fiscal year ended June 30, 1890	4,941
Fiscal year ended June 30, 1891	4,591
Fiscal year ended June 30, 1892	5,018
Fiscal year ended June 30, 1893	5,109

The total number of rejections during each of the past five years was as follows:

Fiscal year 1889	18,694
Fiscal year 1890	16,877
Fiscal year 1891	17,377
Fiscal year 1892	17,244
Fiscal year 1893	14,944

Conclusions.—1. That the rules and regulations governing the Examining Surgeon, in the physical examination of the recruit, be separate and distinct from those that govern the Recruiting Officer, who is not a medical man.

2. That the room in which examinations are to be made should not be less than twenty feet square, well lighted and ventilated.

3. That the unit of measure be as small as possible, and that the metric system be used.

4. That the recruit be measured in the horizontal instead of the upright position, as at present, so that the large number of men now rejected as being below the standard, be saved to the service.

5. That this method of measurement be used so that the exact value of height be obtained in its relation to the other physical equivalents of age, as they are governed by nativity.

6. That weight be determined by a uniform system, the metric, and that the apparatus consist of scales of the simple bar and weight pattern rather than the old style.

7. That special pains be taken to fix this physical equivalent, so that its proper relation to height and age could be determined for each separate nationality.

8. That the chest-girth be changed to conform to the present standard of weight and height.

9. That special attention be given this, so that proper ideas may be obtained in the relations of this "physical equivalent" to weight, height, and age, as it affects each particular race in this country.

10. That data be collected from our present statistics in relation to age, height, weight, chest-girth, chest expansion and capacity of each separate nationality, so that a better and more exact basis of selecting the recruit could be made.

11. That the spirometer, or some modification of it, be used as an aid in determining vital chest-capacity, also that calipers be authorized so as to measure depth of chest.

12. That the present method of determining hearing be modified as I have indicated.

13. That the test for vision be changed as before mentioned, and that the prisoptometer be placed in general use for the determination of simple refractive defects.

14. That it be no longer obligatory to determine with such exactness the age and size of piles, but that this condition be left to the discretion of the surgeon.

15. That the paragraph relating to varicocele be expunged, as our present instruments of precision cannot measure the fine pathological distinctions insisted upon.

16. That the *physical* as well as the *actual age* of the recruit be entered by the Examining Surgeon upon our examination forms, thus arriving at a closer determination of those equivalents which fix the limits of the "military period" of service.

Swiss Medical Students.—The number of students in the five universities of Switzerland during the year 1890–91 was nine hundred and forty-one, and during the summer semester just passed nine hundred and sixty-five.

BORDERLANDS AND CRANKDOM.

By JAMES WEIR Jr., M.D.,

OWENSBORO, KY.

When that bilious critic and merciless crucifier of human foibles, Carlyle, wrote that nine-tenths of the world were fools, he was much nearer truth than most men think. When we take an introspective view of our sane personality, we shudder to see now near it is to the borderlands of insanity and the bizarre and eccentric world of crankdom. There hardly lives a man who does not possess some eccentricity, or who does not cherish, hidden, perhaps, deep within himself, some small delusion, which he is ashamed to acknowledge to the outside world. Social relations and the iron rules of custom, hold in place the balance-wheel of many a disordered mind. The mental equipoise is kept at the normal standard only by the powerful aid of the will, supported and assisted by extraneous adjuvants, such as fear of punishment, fear of personal harm, and, above all, by the fear of ridicule. Many a man hugs his delusions closely to his heart, indulges them only in the secret recesses of his soul, and, their sole owner and acquaintance, carries them with him to his grave. Any man who has a retentive memory, and one capable of minute analysis, can look back in his life and recall moments when his insane personality got the better of his will, and ran riot in forbidden pathways. He may not have committed an insane act. Yet the thought, the impulse, the delusion was there and only outside influences kept it from breaking forth. Who fails to remember certain times in his life when he has had an almost overpowering desire to cry out in church, or to laugh on some sad or solemn occasion; or, having a razor in his hand, has had an impulse, sudden and intense, to draw it across his throat; or, being on some high place, has been seized with the desire to hurl himself downward? This shows how near indeed the healthy mind ever hovers on the borderlands of insanity. Man stands so close to the portals of insanity that he can look through the gateway, when he takes an introspective view of his psychical being, and can see the phantoms and mental ghosts of his insane personality. We have every reason to believe that, among civilized races, there is a vast amount of latent insanity. Taking the tables of our insane asylums, we find a thousand and one causes given as the exciting factors in the mental overthrow. Love, religion, anger, disappointment, etc., down through the long list of psychic and æsthetic emotions, until it seems as though even a breath of wind would be sufficient to destroy the mental equipoise. Among savage and uncivilized races, insanity is of infrequent occurrence. Only when a race begins to elevate itself and take on a higher view of morality, when new rules and new laws, new customs and innovations, tending to place individuals in a state of comparison, arise, does insanity make its appearance. The untutored savage, living in a state of communism, is untroubled by the jealousies and heart-burnings of his civilized congener. He lives in the to-day and allows the to morrow to care for itself. Devoid of ambition, a mere animal, sensual and indolent, he cares only for the gratification of his physical desires. The mental attributes of a civilized being are, in him, wanting.

Psychos is the result of evolutionary development, and the chief reason why insanity is not as prevalent in the savage as in the civilized man, is because the brain of the savage lacks development. I do not wish to convey the idea that insanity is purely psychical in its nature. Insanity is the result of a material change in the structure of the brain produced by morbific action. The manifestations of insanity are merely the symptoms of a disease that involves the brain. The savage has less development of psychical function, consequently he is less liable to mental lesion. I mean by psychical function that portion of the brain in which psychos has its origin. Alienists consider the habits of men as being the factor in the production of insanity. Habits and

heredity are undoubted factors in the production of diseased minds, and, in fact, are the chief agents. You cannot, however, expect to find a disordered function where that function is absent. Savages have paresis, apoplexy, and imbecility, seldom or never insanity. The reason is patent—they lack the psychic function, that peculiar element, whatever it may be, which raises civilized man so high above them. That this element can be developed in savages I do not for one instant deny. The ploughshare of evolutionary civilization will bring it to the surface sooner or later, and when it does insanity follows. I have only to point to the American negro to prove the truth of my proposition; even he is partially exempt, simply because his civilization is of such recent date that his brain has not yet acquired its full quota of the psychic element. I will venture to assert, so true is the fact that insanity is the product of civilization, that, if it were not for the combating influences of social laws, assisted not a little by scientific medical aid, all North America could not contain the vast and enormous army that would constitute the civilized world's array of lunatics. There seems to be in the minds of men an instinctive awe of anything that appertains to the insane. In olden times a disordered mind was considered of divine or diabolic origin as it evinced good or evil tendencies. This belief lasted even until the present century. Many old women who were the victims of senile dementia and kindred ills, were accused of witchcraft and intercourse with the devil, here in the United States, not a century ago. Witches were executed in England and men burned at the stake in Spain, not two hundred years ago, for the crime of demoniacal possession. Even in this enlightened age men are accustomed to consider insanity rather from its psychical standpoint than from its physical aspect. They do not take into consideration the fact that insanity is due to a physical lesion, and that its vagaries are but the symptoms of brain disease or brain deformity. The inhabitants of the borderlands are invested with a certain shadowy mystery which separates them from the rest of mankind, and which makes them appear to us as denizens of another psychical world than ours. In the Middle Ages, cranks, whose eccentricities took a religious turn, were considered holy. St. Simon Stylites was a very pronounced crank, and a very holy man also, because he chose to live the greater portion of his life perched on a pillar seventy feet high. St. Anthony was another holy crank who never, in all his life, washed his feet. Poor Joan of Arc was burned at the stake because she was "possessed of a false and lieing devil." She has been recently canonized by the same church that burned her, and thus, in a measure, had justice done her. I do not think, however, that this is any recompense for the terrible agony inflicted on this unfortunate victim of hystero epilepsy.

Says Maudsley in "Responsibility in Mental Disease": "Some of the prophets of the Old Testament presented symptoms which can hardly be interpreted as other than the effects of madness; certainly if they were not mad, they imitated very closely some of its most striking features." Jeremiah takes a long journey to the river Euphrates and hides a linen girdle in a hole of a rock. He then returns home and in a few days makes the same journey, and finds the girdle rotten and good for nothing. Ezekiel digs a hole in the wall of his house, and through it removes his household goods, instead of through the door. Hosea marries a prostitute because he said he had been commanded by God so to do. Isaiah stripped himself naked and paraded up and down in the sight of all the people. Some of the greatest changes in the world's history have been effected by dwellers in the borderlands. Mahomet was an epileptic and his first vision was the result of an epileptic convulsion or seizure. The character of his visions was exactly like that of those visions which an epileptic sees and describes at the present time. Mahomet believed in his visions and, what is more, got more than half the world to believe in them also. Gautama was a dweller in the borderlands, yet his followers now number five hundred millions. The novel mode in which an insane man regards things may be an inspiration which reflection could never attain, and it sometimes happens that opinions which seem to the world to be the ravings of a madman, have turned out to be true. The insane man has the world against him, and though he may pose for a short time as a reformer, sooner or later lands in the asylum. It sometimes happens that the crank will succeed in getting converts. A notable instance is Schweinfurth, or "the Christ," as he calls himself. I am firmly convinced that this man believes in his delusions. One thing is certain, and that is, his disciples believe in him implicitly. This man is dangerous to society, inasmuch as he has caused the separation of several wives from their husbands; the wives abandoning their husbands to follow him to "Heaven," as he calls his farm house. The crank is, generally, a harmless individual, and is not anti social unless his delusions take the form of homicidal impulse, pyromania, kleptomania, etc. Homicidal impulse is the most dangerous to society of the many mental vagaries and derangements, which afflict the dwellers in the borderlands. Its invasion is sudden and its impulse is, generally, overpowering. A man may be walking the streets presumably in perfect health, and yet have, all the while, a voice whispering in his ear "kill, kill." His insane desire at length reaches its acme, and he throws aside every mental restraint and kills the first individual he may chance to meet. Again, he may desire to kill some particular individual, and will carefully and systematically arrange his plans for the successful enactment of the homicide. The murderers of Garfield and Harrison, probably belong to this latter class, though in the case of Prendergast, the slayer of Mayor Harrison, this opinion may be erroneous. There is something about his photograph that leads me to believe that he is a moral imbecile, rather than an intellectual dyscrasiac. A clerk in a solicitor's office, at Alton, Hampshire, England, one afternoon took a walk outside the town, when he met some children. He persuaded one of these, a girl of nine, to go with him into a neighboring garden. A short while after, he was seen walking quietly home; he was seen to wash himself in the river and then go back to his office. The little girl did not return home, and, search having been instituted, her dismembered body was found strewn about the garden. The clerk was arrested, and in his diary was found this entry recently made: "Killed a little girl; it was fine and hot." This man was either a sadistic sexual pervert, or a victim of homicidal impulse. Maudsley gives this instance as an example of the latter, while Kraft Ebing gives it as an example of the former.[1] There is a great difference between these two mental derangements. The victim of homicidal impulse kills without any ulterior object, while the sadist kills in order to gratify his unnatural and perverted sexual appetite. The victim of homicidal impulse is, to all outward appearances, perfectly sane otherwise. His impulse frequently leaves him for years and then returns with overpowering force. Epileptics who have just passed through violent convulsions, will frequently attack bystanders with great fury. Some alienists declare that homicidal mania is frequently only a masked epilepsy. All epileptics should be carefully watched; they may become dangerous to society at any moment. Numerous instances are recorded of murder committed by sufferers from petit mal, a mild form of epilepsy. I once saw a negro walk up to a white man, who was a stranger and unknown by him, and fell him to the earth by striking him with a club. The negro was arrested, and the next day swore that he was entirely unconscious of having struck anyone. It was proven on his trial that he was subject to mild epileptic attacks.

I believe that all suicides are due to mental aberration. It may be the result of a momentary and sudden loss of

[1] Maudsley: Responsibility in Mental Disease, p. 162, and Kraft Ebing: Psychopathia Sexualis, p. 63.

mental equipoise, or the final and fatal ending of a premeditated desire carried through days, weeks, months, and even years. We see a man blessed with everything that makes life enjoyable. Genial, gay, with the ready smile and kindly word for everyone, suddenly, in a moment, pass forever out into the unknown, self-killed, a victim of his own creation. We stand amazed! Why did he do it? We can find nothing in his past or present condition to warrant such an action. He was the victim of momentary aberration, or, perhaps, deep in his mind, buried and hidden even from himself, the desire for self-slaughter, when a "physical pain, an unexpected impression, a moral affection, an indiscreet proposition"[1] unearthed this desire, and he at once committed the deed. There are epidemics of suicide. Let the papers chronicle some peculiar method of suicide selected by some unfortunate, and others will immediately follow his example. Unconscious cerebration has also hurled many souls into eternity. I was called to see a gentleman who had attempted suicide by slashing the radial artery at the wrist. I found him holding a compress on the severed vessel and greatly alarmed. "He swore to me that he was totally unconscious how he had come to do the deed, and did not know that he had cut himself till he felt the pain of the wound."[2] I think that effemination and viraginity are due rather to abnormalities and deformities existing in the brains of their unfortunate victims, than to mental disease. Mild forms of these types of degeneration are very abundant. The effeminate cigarette-smoking, soda-drinking young man, and the loud, horsy, masculine young woman are seen everywhere. Effemination and viraginity are the results of the weakening effects of luxury and consequent debauchery. Nations have felt the dire force of effemination and have sunk beneath it. The Grecian, the Roman, and the Egyptian races are examples. The satirists of the golden age of the Latin people dipped their pens in gall and bitter wormwood and berated the effeminate nobility time and again. One advised the Roman ladies to look for men among the gladiators and the peasants.[3] Anacreon's poems are full of allusions to effemination and the delights of psychic hermaphroditism. In the time of Louis XVI. of France, the royal palaces were filled to overflowing with effeminants, who vied with the ladies in the splendor of their robes and the eccentricities of their conduct. The case of Alice Mitchell, who killed Miss Johnson in Memphis not long ago, was one of pronounced viraginity. Fortunately for the good of the community there are few viragints. The careful mother punishes the tom-boy girl for her hoydenish habits, and thus, early in life restrains her unnatural masculine tendencies and turns her thoughts toward feminine pursuits and desires. The unfortunate effeminant, however, is encouraged in his feminine tastes and habits by his unwise mother, who likes her boy to sit beside her to sew or knit, as the case may be. She discusses matters of the toilet with him, and, in fact, treats him as she would a daughter. In the end his psychic hermaphroditism becomes complete, and one more unfortunate goes out into the world to swell the ranks of crankdom. Kleptomaniacs are greatly to be pitied, for they are generally women in whom the moral sense is very much developed. The kleptomaniacs will steal any and everything. They are like magpies in this respect. An acquaintance of mine, a most estimable lady, a devout Christian, and a most exemplary wife and mother, is the most incorrigible thief I ever saw. She has often picked my pockets while I was engaged about her sick-bed. The merchants of the town where she lives know her infirmity, watch her while she is in their shops, and respectfully and kindly relieve her of her pilferings when she starts to leave. She expresses great sorrow for her unfortunate insane impulse, and has often begged her husband to have her placed in an asylum. This he refuses to do, as she is perfectly sane otherwise. The husband was called away for several weeks, and on his return took me to his house and showed me her room. In the room were the objects stolen during his absence. It was the most miscellaneous collection of valuables and trash I ever saw. She had gathered together everything from a darning needle to a tombstone, a small specimen of the latter forming a part of this heterogeneous collection. This form of partial insanity is much more frequent than people suppose, and the antecedents of shop-lifters and the like should be carefully examined before a judgment on their criminality is passed. "Eccentricity is certainly not always insanity, but there can be no question that it is often the outcome of insane temperament, and may approach very near to or actually pass into insanity."[1] Alienists rely on the eccentric and peculiar changes which take place in the characters of their patients, who either present themselves or are brought to them for treatment, to establish their diagnosis. If a modest and truthful man suddenly becomes a braggart and a liar; or, if a humane man becomes cruel, or a neat man slovenly, there is reason to suspect brain trouble. The intellect may appear intact, so also the reasoning powers, but these eccentricities indicate a deviation which may lead to mental destruction. The last faculty in the mind of man to develop, is the moral faculty. This faculty is the one first lost by diseased brains. If a man suddenly becomes dissolute and licentious, who, heretofore, has led a virtuous, moral life, if he be examined, in nine cases in ten, his brain will be found to be diseased. The little cloud, which at first is no larger than a man's hand, grows ever larger and larger, and in the end overspreads the entire mental sky.

A SIMPLE MEANS OF INCREASING THE APERTURE AND IMPROVING THE PERFORMANCE OF SOME IMMERSION LENSES.

By HENRY G. PIFFARD, A.M., M.D.,
PROFESSOR OF DERMATOLOGY, UNIVERSITY OF THE CITY OF NEW YORK.

During the past few years opticians and observers have sought to obtain increased visibility of minute objects by various improvements in their optical apparatus, and in the accessories used in connection therewith.

The highest point thus far reached has been obtained by the Zeiss establishment, in the production of their 2.5 mm. immersion lens with a numerical aperture of 1.60. With this objective used in connection with proper accessories and under conditions prescribed by the maker, finer and probably more truthful images can be obtained than is possible by any other means now known to science. To obtain these brilliant results, however, it is necessary to have at command a more effective sub-stage illuminator than those commonly in use; to employ special slides and covers, and special mounting and immersion media. To speak more definitely, the illuminator is of the Abbe type, built with a numerical aperture of 1.60, when used with immersion contact. The slide should be of flint glass having a refractive index of 1.72; the object must be mounted in a medium having an index of 1.60 or higher, and the cover glass must also be flint, with index same as that of the slide. The immersion fluid is mono-bromide of naphthalin with an index of 1.65. To avoid the necessity of an adjusting collar, Zeiss corrects the lens for a definite cover thickness, namely .17 mm. The lens is apochromatic, fluor spar being used in its construction. The price of this outfit, duty paid, is as follows: condenser, $14; slides, 80 cents each; cover-glasses, 40 cents each; objective, $320. As the lens is apochromatic it is liable to early deterioration, which, however, will be made good, we believe, under the general guarantee of the maker as regards apochromatic lenses.

In the special study of diatoms this lens stands unrivalled, but in many other branches of investigation it is

practically useless. I have worked with this lens, and can fully corroborate the statements that have been made concerning its excellence in the special lines of investigation to which it is adapted. One of its accessories, however, the condenser, should be reckoned as a disgrace to even a third-rate optician.

If we desire to appreciate the advantages possessed by the high numerical aperture of 1.60, it would be well to analyze the factors that contribute to the result, and to compare them with the same elements involved in the operation of the immersion objectives in common use. For purpose of comparison I select an oil-immersion lens of N. A. 1.30, accompanied with its usual accessories.

	Zeiss, N. A. 1.60.	Oil-immersion, N. A. 1.30.
Condenser	N. A. 1.60	N. A. 1.40
Slide	Index 1.72	Index 1.52
Mounting medium	Index 1.60 or higher	Index (balsam) 1.54
Cover-glass	Index 1.72	Index 1.52
Immersion fluid	Index 1.65	Index (cedar oil) 1.515

At every point, then, it will be seen that the Zeiss outfit possesses factors of superiority (as regards performance within certain limits) over the lenses more frequently met with. Any means by which these differences can be minimized would seem, therefore, to be worthy of consideration.

If we examine the present status of the optical art as regards the sub stage condenser, we can readily place these instruments in three classes, namely: low, medium, and high grade. The chromatic condenser N. A. 1.40, commonly known as the Abbe, may be placed as regards general utility in the first category (low grade). It is a cheap, but unsatisfactory, substitute for an achromatic condenser of the same or even lower aperture. The condenser can be obtained from the majority of opticians for about twelve or fifteen dollars. In the medium grade should be placed the achromatic condensers of N. A. 1. These are more expensive than the Abbe, but so far as my experience goes, are superior to it in every respect, except for the single purpose of demonstrating bacilli in tissues and sputum. They cost about twenty dollars. The only existing strictly high-grade condensers that I know of are the achromatic and apochromatic condensers of N. A. 1.40 made by Powell & Lealand, of London. These will cost, laid down in New York, duty paid, about one hundred and twenty dollars each. This price will prove prohibitory to many, and it is to be regretted that American opticians have not as yet found a way to produce a condenser of equal merit at a price that would bring it into more general use.

Flint-glass slides and covers are much too expensive for ordinary purposes, and except in connection with the Zeiss 1.60, are less desirable than crown. If used in connection with the ordinary objectives, they introduce an amount of negative spherical aberration that disastrously affects the definition.

The increased visibility given to certain structures by the use of mounting media of high index, is a subject that merits more attention than it has hitherto received, as it constitutes one of the factors that contribute to the best final result.

The homogeneous immersion lenses of N. A. 1.30, owing to their comparative cheapness, are the ones most commonly in use in bacteriological and biological work, but are far from being the highest expression of the optical skill of the present day. Zeiss, it is true, lists a lens with N. A. 1.40, but cautions against its use on account of the insecure fastening of the front lens.

For thirty years or more American and English opticians have led the world in the production of strictly high-grade objectives; and to-day better lenses can be obtained in either of these countries than are made in any part of the Continent of Europe. By far the best dry lenses[1] are made in America, while a single London firm (Powell & Lealand) leads all competitors in the manufacture of water-immersions of high aperture. The oil-immersions made in America reach apertures of N. A. 1.38 and 1.42, and within the range of their aperture surpass any foreign production that I have had an opportunity to examine. American opticians, however, have not thus far exceeded (commercially) a numerical aperture of 1.42. These lenses cost, for a $\frac{1}{10}$-inch or $\frac{1}{12}$-inch, from about eighty to one hundred dollars.

Powell & Lealand, however, in oil-immersion lenses have reached a numerical aperture of 1.50, for which they ask the following prices: $\frac{1}{8}$-inch, £35; $\frac{1}{12}$-inch, £40, and $\frac{1}{20}$-inch, £60. To estimate the American price, duty paid, reckon each pound at eight dollars. I mention these figures in order that the commercial value of these extra-high apertured lenses may be clearly appreciated, and to emphasize the importance of obtaining them, if possible, by means that shall not involve such great expense in their production.

About seventeen or eighteen years ago I purchased of Powell & Lealand a $\frac{1}{4}$ inch water-immersion, rated by its makers as having an angular aperture of 143°.[1] This would correspond to a numerical aperture of 1.26, and is, I believe, the highest aperture ever given to a water-immersion lens. The price of this objective was £12. Two or three years ago I discovered that it would work perfectly well with cedar oil, which raised its aperture to N. A. 1.44.

More recently I have ascertained that, by closing the systems as far as the correction collar would permit, and shortening the tube length to about 155 mm,[2] that the objective would correct perfectly with mono-bromide of naphthalin. Not only was the overcorrection introduced by the mono-bromide completely neutralized, but the character of the image remarkably improved.

I next investigated the possibility of error in the makers' statement as to the angular aperture, and found that with systems open and water contact the angle measured 143°; with systems half closed and oil contact the angle was 144°; and with systems entirely closed, using mono-bromide contact, the angle was also 144°. Applying the usual formula N. A = n. sin. u, the result gave N. A. = 1.56, the highest aperture, so far as known to me, that has ever been obtained with an achromatic lens, working with crown-glass slides and covers.[3] With the lens used in this manner I have resolved the Amphipleura pellucida on a dry mount, and this has been separately verified by my friend, Mr. H. C. Bennett, of this city. I mention this fact in order to show that the lens remained in a state of perfect correction, and stood up to the high eye-piecing which was needed to amplify the image to a point that would enable the resolution to be seen.

A duplicate of my lens and a Powell & Lealand $\frac{1}{8}$-inch water-immersion, N. A. 1.26, the property of Dr. William Stratford, were also found to correct perfectly with the mono-bromide. A $\frac{1}{8}$ inch oil-immersion, N. A. 1.50, of the same makers, failed to do so, possibly owing to insufficient range of adjustment.

Two American oil-immersion lenses of $\frac{1}{10}$-inch equivalent focus, rated by their maker (Spencer) as having N. A. 1.32 and N. A. 1.38, were next tried with mono-bromide, and found to respond to it perfectly, it being necessary, as with the others, to close the systems and shorten the tube length. I carefully measured the angular aperture of one of these with water, oil, and with mono-bromide: I found that its numerical aperture with water was 1.22; with oil, 1.39; and with mono-bromide was 1.51.

A Bausch & Lomb oil immersion, $\frac{1}{12}$-inch N. A.

[1] I refer to the strictly high-grade lenses of wide angular aperture. The medium angle dry achromatics of Leitz, however, are worthy of the warmest praise.

[1] The expression "Numerical Aperture" had not at that time found a place in optical nomenclature.

[2] It was intended by its makers to work with a tube length of 250 mm.

[3] As there may be some who do not understand the meaning of the equation N. A. = n. sin. u, I will state that n stands for the index of refraction of the medium that lies between the cover-glass and the front lens of the objective, be the same air (n = 1); water (n = 1.33); cedar-oil (n = 1.515), or mono-bromide of naphthalin (n = 1.65). Sin. u represents the natural sine of half the angle of aperture. In the case of the $\frac{1}{4}$ inch Powell & Lealand lens, whose angular aperture was 144° the N. A. = 1.65 × Sin. 72° = 1.65 × .951 = 1.569.

1.42, corrected perfectly with mono-bromide, giving an aperture, by calculation, of N. A. 1.54. Several other immersion lenses that I have tested failed to correct.

A striking peculiarity of the images obtained with mono-bromide immersion was the partial effacement of the secondary spectrum, approximating in character the image obtained with an apochromatic, but not to the same extent.

In order to obtain the full benefit of the increased apertures obtainable by the means here stated, it is necessary to have at command adequate sub stage illumination. The nearest approach to this that is at present available, are the achromatic and apochromatic condensers N. A. 1.40 of Powell & Lealand; or, as a cheap but less desirable substitute, the Zeiss chromatic condenser N. A. 1 60.

The experiments here related can be readily repeated by those possessing suitable objectives, namely, adjustable immersions corrected by their makers for the long tube (216 mm. or longer). It would be folly to attempt to obtain the same results with the medium-grade non-adjusting German immersion lenses which in late years have come to this country in such large numbers.

The ideal immersion lens for general bacteriological, biological, and histological research, it appears to me, would be one having the largest practicable angular aperture, and corrected for either the 160 mm. or 216 mm. tube, and a cover-glass not exceeding .20 mm. The adjustment should be arranged to close a little beyond the mono-bromide point, and open a little beyond the oil point, so as to permit the objective to be used at will with either fluid. It is possible, however, that the optician with mono-bromide in mind, would find it desirable to make some slight changes in his present formulas.

Having here shown a means whereby the true inwardness of minute objects can be displayed to better advantage than has heretofore been the case, I leave the further development to those who desire to avail themselves of these aids, and to the opticians whose business it is to supply them.

10 West Thirty-fifth Street.

GUAIACOL AS A TOPICAL APPLICATION IN THE TREATMENT OF ACUTE TONSILLITIS.

By JAMES HARVEY RAYMOND, M.D.,

CHICAGO, ILL.

INSTRUCTOR IN SURGICAL PATHOLOGY AND ASSISTANT IN CLINIC DISEASES OF NOSE, THROAT, AND CHEST, RUSH MEDICAL COLLEGE; ATTENDING PHYSICIAN TO THE CENTRAL FREE DISPENSARY, DEPARTMENT NOSE, THROAT, AND CHEST.

The etiology of tonsillitis, from the various hypotheses advanced by the most eminent laryngologists, seems to be as obscure as is the definite knowledge of the function of the tonsil. It is believed by many to be due to the essential cause of rheumatism; that it is the precursor or result of an acute attack of rheumatism; that it is due to an inherited tendency—the so-called rheumatic diathesis. By others it is thought to be of neurotic origin; the result of malnutrition; the errors of diet; the inhalation of sewer gas. Wet and cold and bad hygienic surroundings are considered as exciting causes.

Pathologists who have made this disease a study, among whom the names of Fränkel, Frederici, Gaffi, Schnell, and Richardiere are most prominent, attribute it to the action of pathogenic micro-organisms or their ptomaïnes, and present as strong corroborative evidence the facts revealed by microscopic examination.

Its clinical course shows a clear analogy to acute inflammations in other tissues. The symptoms of inflammation are too well known to mention here, but it is well to bear in mind that in all inflammatory conditions we do not find typical symptoms. Very much depends upon the anatomical seat of the process, the temperament of the patient, and the quantitative and qualitative conditions of the exciting cause.

Accepting the theory that inflammation is caused only by pathogenic microbes or their ptomaïnes, the so-called rheumatic diathesis, as well as the other etiological factors enumerated, seem to me only conditions that create a favorable soil for their growth and multiplication, cold being perhaps the most frequent predisposing cause. It is easy to understand how a weakened condition can be brought about in the tissues of the throat, especially in patients of a strumous or rheumatic diathesis. Pathological conditions of the nasal cavities that cause obstruction to nasal respiration give rise to congestion of the throat. This condition existing in poorly nourished patients adds greatly to their chances of having tonsillitis, since many kinds of bacteria are present at all times in the mouth, and have easy access to the most remote parts of the lacuna of the tonsils, where they lodge and multiply. Microscopical examination of the acutely inflamed tonsil reveals large colonies of staphylococci, streptococci, and many other species of bacteria commonly found in the mouth, in and about the lacunæ, with the characteristic histological elements of an inflammatory exudate.

The inflammatory process may exist in the mucous membrane, originating in the lacunæ, when it is commonly called follicular tonsillitis. It may attack the parenchyma of the glands, when it is called quinsy, and lastly it is found to attack the peritonsillar tissue. Lenox Browne states that quinsy implies acute inflammation, limited to, or at least originating in, the parenchyma of the glands themselves. Lefferts, of New York, states that the abscess is not in the tonsil, but in the peritonsillar tissue.

When it attacks the mucous membrane we find the same conditions that are common to inflammations in mucous tissues elsewhere.

We have the characteristic pathological changes of the capillaries, with plastic exudation composed of the exuded blood-corpuscles and the products of their disintegration, together with the detached epithelial cells These elements, mixed with the hypersecretion of the intact epithelial cells, fill the orifices and coalesce to form the pseudo-membrane seen about the ducts and sometimes covering the entire tonsil.

It is not an easy matter to differentiate between the parenchymatous and phlegmonous variety. The latter is due to emigration of microbes into the connective-tissue spaces, where they locate and multiply. In the former the blood-vessels supplying the parenchyma, which have undergone alteration by the inflammation, furnish an avenue of escape for microbes, that directly attack the secreting cells, giving rise to characteristic pathological changes, observed in parenchymatous inflammation. If their action is not arrested by antiseptic treatment, or by the physiological resistance of the tissues, the process becomes chronic, or the formation of an abscess is the result if pyogenic micro organisms are present and their intensity too strong to be overcome.

The determination of the exact location of the atrium of infection is a matter of very little or no practical importance.

If the interstitial tissue is the seat of localization of the infective microbes, the parenchyma is very apt to become involved, and *vice versâ*.

With these views the indications for treatment would be the application of antiseptic remedies, that would at once render inert the pathogenic micro-organisms or neutralize the substance formed by them that acts as the exciting cause.

The author in his experiments with guaiacol, during the past few months, has demonstrated that this drug is entitled to be considered a valuable remedy in the treatment of this affection.

He has had an opportunity of observing its effects in a large number of cases in the clinics of Professor E. Fletcher Ingals, and of the Central Free Dispensary, and in private practice. The result was that of marked relief in the majority of cases treated. At my solicitation Professor A. C. Cotton has given it a trial. He reports marked and immediate improvement in over ninety per

cent. of the forty-two cases in which he has applied guaiacol to the tonsil. Dr. John Edwin Rhodes reports having used the remedy in a number of cases with marked benefit, and mentions one case in which there were evidences of a speedy suppuration in the tonsil which was speedily relieved by the guaiacol. He has also used the remedy in facial erysipelas, and reports that the inflammation seemed to be checked, and relief was promptly afforded by the application. My friend Dr. Arthur M. Corwin has of late been applying the remedy in all cases of acute tonsillitis and pharyngitis which have appeared at his clinic at the Central Free Dispensary and in private practice, and reports fifteen cases, a few of which seemed to give promise of a phlegmonous course. In every instance there was improvement of all the symptoms and signs after the first application, and in none did suppuration occur. Three cases were apparently aborted within twenty four hours, and subsided almost completely after the second application, made after an interim of forty eight hours.

Of my own cases, in every one, except three, pure guaiacol was applied. In the others it was thought that a fifty-per-cent. solution in oil of sweet almonds, applied with an atomizer, would be sufficient, but it proved of much less value than the pure drug.

As might be expected, the application is somewhat unpleasant and is attended with quite a little smarting, but as its duration is only from one to five minutes in most cases (although in some instances it lasted for several hours), the relief immediately following more than overbalanced the pain caused by the application. However, it is frequently no more painful than nitrate of silver, or many other remedies commonly used, and possesses many advantages over them, the cardinal one being as a curative measure or an abortifacient. It was thought that a thorough application of cocaine (ten per cent. solution) prior to the application of guaiacol would lessen the degree of smarting, but it seemed to aggravate it. The applications were made by means of a cotton swab dipped into pure guaiacol, and applied over the surface of the tonsils, care being taken to prevent it from getting into the larynx. To keep the throat moistened, troches of althea, or guaiac, or gargles were given. In every case where marked febrile symptoms were noted, the temperature was found to drop from one degree to normal within a few hours. In one case where it registered 103.5° F., it fell to normal in four hours.

In the superficial or lacunar variety, the inflammation was terminated far more speedily than in the phlegmonous.

In a number of cases with a history of having had quinsy, and where every evidence of a recurrent attack was present, it was found that not more than two applications were necessary to abort the disease, and in many instances it did not last more than forty-eight hours, and in none did suppuration occur. In many cases where patients were unable to swallow without intense pain, they were able to do so within ten minutes. In a few patients suffering a primary attack, swelling was seen to subside within a few hours.

I have omitted tabulating or describing each case separately, but I am quite satisfied that pure guaiacol applied locally, early in an attack of acute tonsillitis, on account of its penetrating the tissues deeply, acts as a most efficient antiseptic. I believe it arrests the action of pathogenic and pyogenic microbes, which, when accomplished, speedily ends the inflammation and prevents suppuration, often aborting one of the most painful acute affections of the throat the physician is called upon to treat.

36 Washington Street.

American Chloroform.—Dr. Squibb has made a number of tests of the different brands of chloroform in the American market. He finds some impure, but none very bad, and he thinks that American chloroform is, on the whole, purer than that used in Europe.

Clinical Department.

A RARE FORM OF FOREIGN BODY IN THE MALE URETHRA.

By HERMANN GOLDENBERG, M.D.,

NEW YORK.

The patient was aged thirteen, and was referred to me in May, 1893, with the following history. I purposely reproduce the story as it was imparted to me; supplementary hints, essential to an accurate knowledge of the case, will appear later.

It was alleged that the boy had had the first urinary symptoms two years previously, during the transatlantic voyage to this port. As regards the diagnosis and subsequent treatment no complete data were obtainable. At any rate, he was entirely recovered at the end of a week, and was free from distress from that time up to two weeks ago, when he was suddenly taken ill with severe "pains in the stomach," which was followed by great distress upon micturition; the latter became so intense that spontaneous evacuation of the bladder was impossible during the previous three days. The urine flowed away involuntarily in drops, the tenesmus continuing uninterruptedly (Ischuria paradoxa). It was said that on the day preceding a physician had emptied, or attempted to empty, the bladder, without, however, discovering the cause of the retention.

Status Praesens.—The patient entered the room groaning with pain, his body bent forward, and his abdomen supported by his outstretched hands; the greatly enlarged bladder, extending as high up as the umbilicus, appeared at once to view upon disrobing him. External pressure upon the bladder caused the patient to cry out; no other abdominal changes could be noted. The urethra was slightly reddened and swollen; the lips of the meatus injected, moderately swollen and everted, and gave exit to foul-smelling urine. Upon palpating the penis, a hard movable body, about the size of a bean and lying in the long axis of the organ, could be made out about an inch behind the meatus; it was regarded as a urethral calculus.

After cocainization of the anterior part of the urethra, an attempt was made to extrude the supposed stone, but it impinged at the narrow portion of the meatus; the latter would only admit the passage of a No. 14 F. sound. Upon dividing the meatus with the knife, the body was then readily extracted.

Greatly to my astonishment it was not a calculus, but a medium sized date-pit, the thicker and distal end of which was about the size of a No. 21 F. sound, the thinner proximal end that of a No. 17; its cortex was superficially eroded at several places, laying bare its organic framework. The urine which was subsequently voided was very cloudy and of foul odor; unfortunately a chemical and microscopical examination was neglected.

Query: How did the foreign body enter the urethra? My first thought was that the boy had, for obvious reasons, introduced it there himself; he denied this absolutely and emphatically upon the closest cross-examination; notwithstanding this, his denials would not have influenced me, for even adults will dally with the truth in *puncto genitalium*, were it not that there were weighty objective reasons against the tenability of my original conclusion. In the first place it appeared to me to be absolutely impossible, even with the exercise of the greatest force, to push the body through so narrow a meatus: furthermore, the lad had had a similar attack some two years previously; when the pain appeared first in the region of the bladder, not in the urethra. These facts forced me to the conclusion that the date-pit was originally located within the bladder, and that it was washed to the site of its discovery by the urinary current. It was now an object to find out in what manner the foreign body had found its way into the bladder.

Dr. Ladinski, who rendered valuable assistance during

the examination at the Mount Sinai Dispensary, made an exploration per rectum, as it appeared to him probable that the pit had perforated from the appendix into the bladder. He found that the latter was drawn toward the right iliac fossa by strong adhesions. There was, furthermore, a decided tenderness of the appendix vermiformis upon pressure from without. The patient objecting to further examination, I had to postpone rectal exploration and eventually cystoscopical examination; but, unfortunately, had no opportunity to do so at a later time, the patient passing from observation. His condition, I was informed a few days later, was so very good that his parents thought further medical advice needless.

I am quite well aware that incontrovertible evidence in substantiation of my opinion (which was shared by a number of colleagues who saw the case) is lacking; nevertheless, I believe that enough has been found to make my surmise more than probable that originally in this case there was a perityphlitic abscess, certainly encapsulated, and that it and the date-pit perforated into the bladder. When this took place I cannot say. I am not inclined to believe that the foreign body was long in the bladder, in which event there would certainly have been some incrustation; the fact that it was superficially eroded in several places (all who saw it concur in the belief that it was no *arte fact*) may be explained on the theory that it had been for some time exposed to the action of pus in an abscess cavity.

I was at first of the opinion that the changes upon the surface of the pit were accomplished by stomach or intestinal digestion, but at a discussion of the case, which took place at a meeting of the "Wissenschaftliche Zusammenkunft Deutscher Aerzte in New York," I was convinced that the secretions of these organs have no influence upon cellulose.

Regarding the supposition of a precedent typhlitis or perityphlitis, I may here say that the boy was several years ago taken ill with severe pains in the right side of the abdomen, recurring upon two or three occasions in the course of time; since then he has been a sufferer from obstinate constipation, and voids his stools "undigested and in pieces." The parents of the lad had enjoyed a fair degree of material prosperity and educational advantages in their former Russian home, and their statements are entitled to greater respect than may be given to the average of their country-people whom we see in this city.

In parenthesis be it remarked, on the same day that I saw the above case I removed a calculus of respectable dimensions from the urethra of a man of twenty-five years, thus exemplifying the frequently observed "duplicity of cases."

A CASE OF VARICOSE VEINS ON THE FACE AND TONGUE.

By IDA R. GRIDLEY, A.M., M.D.,

COLLINSVILLE, CONN.

A few weeks ago, Mrs. G——, fifty-nine years of age, consulted me about some nervous symptoms from which she was suffering. On examining her tongue I noticed a peculiar appearance which excited my curiosity. Both the upper and lower surfaces are much ridged and furrowed, and studded with irregular elevations, some the size of a large pea. These elevations are soft, purple, and but little covered with the ordinary coating of the tongue. There are five large elevations on the right side and two on the left. The anterior portion is more affected than the posterior. The lower lip, and the buccal mucous membrane are studded with similar small purple elevations.

I questioned her closely concerning the duration of this condition, and elicited the following history:

When she was born a small purple tumor was noticed underneath the chin.

When she was twenty-three years of age, a little red speck the size of a pin's head appeared on her left cheek, and was diagnosed as a "spider cancer" by a female quack calling herself a "cancer doctor." She applied a "fire plaster to draw out the cancer," and produced a large sore which did not heal for two months. A scar, the size of a quarter of a dollar, still remains. Immediately after the sore was made, varicose veins appeared on the tongue, the cheeks, and the side of the neck. Several physicians have thought that this treatment was the cause of the varicose condition. To me it seems more probable that there was a congenital tendency toward enlargement of the veins. She has also varicose veins under the pubes and near the anus.

At times the veins on her tongue and cheeks will swell up and become quite annoying. Once, twenty-one years ago, she burned her tongue with a piece of hot meat and opened one of the veins, causing a hemorrhage which was stopped with some difficulty.

Twice since then she has spit up blood, coming apparently from the throat, not from the mouth.

Aside from these annoyances this peculiar condition gives no trouble.

A CASE OF SUPRAPUBIC DISLOCATION OF THE LEFT FEMUR AND COMPOUND FRACTURE OF THE COCCYX.

By WILLIAM A. ROLFE, M.D.,

BOSTON, MASS.

SURGEON TO BOSTON EMERGENCY HOSPITAL.

The following case is reported because I think it presents a rather rare complication, and also on account of the perfect recovery the patient made after such severe injuries:

F. G——, aged twenty-seven, a machinist by trade, while standing before a high table in his shop examining a drawing, was struck over the sacrum by a large piece of T-iron, which was being run through a planing machine. The force of the blow was sufficient to jam him between the iron and table, and pin him there until the machinery could be reversed, when he was removed. He was brought to the hospital in the ambulance, and on arrival was found to be in a state of marked collapse.

On examination his left thigh was found to be strongly abducted and the whole leg everted, and one and one-half inch shorter than its fellow. In the left groin a round body presented, which was the head of the femur riding over the pubic bone. The skin over the head was so stretched that it was covered with a series of deep fissures, showing that a little more force would have sufficed to render the dislocation a compound one. Over the lower part of the sacrum was a ragged wound four inches in length, full of dirt, and through which the coccyx could be felt at an acute angle to the sacrum and freely movable. The rectum was uninjured.

The patient being etherized, reduction was attempted by flexing the thigh on to the abdomen and forcibly rotating same inward. Great care had to be exercised so as not to force the head of the bone through the groin. After repeated attempts the head of the femur was dislodged from over the pubes, but went with a snap into the thyroid foramen. Owing to the condition of the parts, which had been subjected to a prolonged stretching, this new dislocation was easily reduced.

The injury to the coccyx was not attended to that day, as the patient was in an extremely weak condition. The next morning, being again etherized, the coccyx was excised and the wound thoroughly irrigated, and packed lightly with iodoform gauze, good drainage taking place. For the first week the bladder had to be catheterized, the patient being unable to urinate voluntarily. The urine for a few days was slightly bloody, but gradually cleared up. On the fourth day the bowels were moved by an enema, and from then on the patient made an uninterrupted recovery. At the end of the third week the sacral wound was entirely healed up, and he was discharged.

He complained only of a slight stiffness in the left hip, and could walk very well with the aid of a cane. At last accounts he had resumed his work.

A RARE CASE OF SPONTANEOUS DELIVERY AFTER CHLOROFORM NARCOSIS.

By H. F. EICHACKER, M.D.,

NEW YORK.

The following case will give another illustration of what harm can be done in the hands of a midwife by the internal administration of ergot before delivery, for the purpose of increasing labor pains.

Friday, January 26th, 5 A.M., Mr. T—— called on me to attend his wife during confinement; he requested me to take instruments along, because his wife was instrumentally delivered at her first accouchement, this being the second. On my arrival at the patient's house I found a midwife present, who related the following (very likely) false story. Pains had begun the day before at 11 A.M.; membranes had ruptured at 11 P.M. She had examined woman one-half an hour ago; that child was alive; that she had given two drachms of fluid extract of ergot, and that she was about to give another one.

On examination I found an R.O.A.; going up a little higher the funis could be felt around neck, but pulseless and thin. The shoulders were yet above superior strait; pains very vigorous.

I twice made the attempt to put on forceps (McLane's), but twice they slipped, owing to the fact that the child was dead and therefore the head bloodless and hence easily compressible.

After having informed Mr. T—— that the child was dead, and that in order to deliver the woman she must be narcotized, he went after my friend Dr. Abrahams.

Dr. Abrahams proceeded at once to give the chloroform, which I happened to have in my bag. Several strong attempts at turning the fœtus were made, but with utter failure, owing to the tonic contracture of the uterus. Dr. Abrahams also convinced himself that it was impossible to lift the head out of the pelvis in order to bring down a foot. To be on the safe side we concluded to continue the anæsthesia with ether. While waiting a few moments for the husband to return with the ether, the child made its sudden appearance, simply rolling out of the vagina on the floor, followed by a great gush of blood. After removal of placenta the bleeding was stopped by firm pressure. There was nothing unusual about size of child. The woman herself never developed any untoward symptoms.

66 Columbia Street.

FRACTURE OF THE HEAD OF THE FIBULA BY MUSCULAR ACTION.

By SAMUEL PIERSON, M.D.,

STAMFORD, CONN.

The following case is reported on account of its extreme rarity, and of the perfect result of its treatment. In a cursory search of such authorities as are at hand, I have been unable to find any description or mention of this fracture.

John R——, age thirty, German, on September 4, 1893, was engaged in constructing a stone wall; and seeing that part of the wall was giving way and about to fall upon him, he sprang backward suddenly and fell to the ground; upon attempting to rise he found that his right leg was entirely disabled, although he had not been struck by any of the falling stones; on examination a few hours later, I found a fracture of the head of the fibula; the upper fragment, about three-fourths of an inch in length, was drawn up by the biceps tendon for fully two and a half inches, and the two ends could not be brought in apposition by any means except the most extreme flexion of the leg, and even in this position I found it impossible to keep them in perfect contact.

As the patient's occupation (that of farmer and teamster) made the probable partial disability of the leg a serious matter, I asked Dr. Charles T. Parker, of New York (who was spending the summer here), to see the case with me; he at once advised cutting down and suturing the fragment to the bone; this he did two days later, under strict asepsis.

An incision two and one-half inches long was made down to the bone, small holes were drilled in either fragment, and the two were drawn together with chromatized catgut. The wound was dressed in the usual manner and the leg was put up in a right angled plaster of Paris splint. There was no reaction from the operation and the first dressing was made two weeks later; the wound had healed by first intention throughout. A similar plaster splint was applied and left on for six weeks longer, when all dressings were removed and perfect bony union found to have taken place.

At the present time, four months from the date of the injury, there is perfect motion at the knee joint, and the man is pursuing his usual occupation with entire comfort.

OBSTINATE SINGULTUS.

By CHARLES S. DICKINSON, M.D.,

GOVERNMENT PHYSICIAN, FORT STEVENSON, N. DAK.

Having noticed the relation of several cases of singultus in the columns of the Medical Record, I will give a short history of a case I had recently. On February 5, 1894, Mr. B. T——, a young man, about thirty-three years of age, single, came to my office for treatment, complaining of dizziness, no appetite, lack of ambition, and tenderness in the epigastrium. Almost immediately he was taken with severe paroxysms of hiccough. I prescribed magnesia sulph. one ounce, to be followed by small doses of cocaine, without any benefit. In the afternoon of the 5th I determined to wash out the stomach, which I accordingly did, but without any favorable result. The patient could eat very little, and the food distressed him. No cessation during the night or next day, in spite of pilocarpine and various other remedies. In the evening of the 6th I gave the patient oleum ricini, ℥ ss.; bismuth subnit., gr. x.; ol. piperiti. ♏ij.; this had the effect of controlling them for the night; but early next morning, February 7th, they began again as bad as ever, the remedy of the night before did no good, and the patient was rapidly becoming exhausted. Could not eat anything. I gave morphine in the evening, which gave the patient little snatches of sleep, temporary cessation from hiccough, but ultimately failed of the desired result. On the morning of the 8th they were as bad as ever. I began to despair of giving any permanent relief with the various medicines. A happy thought took possession of me at this juncture. I had some oatmeal porridge made for him, which I had served with milk. This was on the afternoon of February 8th. Quickly hiccough stopped, no recurrence since; patient is doing finely on an oatmeal diet. It was of gastric origin, due probably to irritation of the walls of stomach; the oatmeal served as a demulcent to the irritated mucous membrane. This is, I believe, a new remedy, but it deserves a further trial by all practitioners who meet with this obstinate affection in their practice.

Diminution of the Mortality from Typhoid Fever in Paris.—Dr. Rochard states that the diminution in the lethal effects of typhoid fever has gone on steadily diminishing in Paris during the last twelve years. Thus, in 1869 the mortality reached 53.4 per 100,000 inhabitants, the corresponding figures for 1893 having been 25.7. The reason for this improvement is not far to seek: the dangerous beverage—Seine water—formerly largely consumed, is now replaced by fairly pure spring water, and great progress has been effected in the drainage of the city.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, March 24, 1894.

LEGAL REQUIREMENTS FOR PRACTITIONERS IN DIFFERENT STATES.

THE Illinois State Board of Health has taken great pains in its report for 1894 to compile an account of the present requirements for practising medicine in different parts of the United States. The report is interesting and instructive, not only in showing the progress made in this very necessary department of medical legislation, but it enables us to compare the different States with each other, regarding the advantages of their respective systems. We have also offered us an opportunity for answering in a general way many questions which constantly arise in reference to the existence or not of medical laws regulating practice in particular States.

Altogether the outlook is very encouraging to the advocates of independent State examinations for license to practise, in that it proves the existence of a strong conviction in its favor, and a proper appreciation of its merits on the part of legislators generally. Much, if not all of this sentiment, has been created by the medical profession itself as the result of persistent advocacy of a very just and very reasonable measure of protection against quackery and incompetence, and has in the end tended more than any other means to elevate the standard of medical requirements.

It needs no argument to prove that the most equitable regulation is that of absolutely independent examinations by an impartial State board. In view of the varied standards adopted by different medical schools, and the great difficulty in bringing them to such a uniform degree of excellence as shall guarantee the highest possible order of attainments, there appears to be no other feasible method of compelling necessary fitness. Indeed, this relegates to the background that so-called generous rivalry among the lower grade of colleges for large classes, easy requirements, short terms of study, and, necessarily, unfit preparations.

It is encouraging in this connection to notice that there are sixteen States in which a diploma of itself is no license for practice, and in which an extra and independent State examination is demanded by law before the applicant can be qualified. These States are: Alabama, Arkansas, Florida, Maryland, Minnesota, Mississippi, New Jersey, New York, North Carolina, North Dakota, Pennsylvania, South Dakota, Texas, Utah, Virginia, Washington, and portions of the Indian Territory. They may be considered the banner ones in matters relating to high standards and advanced methods.

In examining the conditions of the remaining States on this question of legal license, we take a second grade in which it is obligatory to register diplomas after they have been supervised either by State Examining Boards, State Boards of Health, or officers of the County or Court, and in which an independent examination, although not obligatory, is sometimes considered necessary. The latitude of privilege under these circumstances is as varied as are the means to make them so. In the majority of instances, as may be readily imagined, it is a mere matter of form, and virtually gives the sanction of law to a mythical and elastic standard.

In this second list are the following States and Territories: California, Colorado, Connecticut, Delaware, Illinois, Iowa, Missouri, Montana, New Mexico, Oklahoma, Oregon, Tennessee, West Virginia, and Vermont. Of these the States and Territories having a State or Territorial Board of Examiners for such optional purposes are: California, Colorado, Connecticut, Delaware, the Cherokee and Choctaw Nations of the Indian Territory, Missouri, Montana, New Mexico, Oregon, Tennessee, and Vermont; while Illinois, Oklahoma, and West Virginia conduct such examinations throughout their respective State Health Boards.

Simple registration of diploma only is demanded in Georgia by the clerk of a superior court; in Idaho by a county clerk; in the District of Columbia by endorsement of the District Medical Society; in Indiana by the County Clerk; in Kansas by the State or County Society or college granting diploma; in Kentucky, Louisiana, and Nebraska by the State Board of Health; in Nevada, Ohio, South Carolina, and Wisconsin by the County Society, and in Wyoming by the Registrar of Deeds.

And, lastly, and with sorrow be it said, Maine, Massachusetts, New Hampshire, and Rhode Island, have no legal regulations whatever. Heretofore all efforts at obtaining proper licenses have failed, and the present conditions for practising are below the requirements of those in the far off Indian Territory. It is well known that the difficulties in obtaining necessary legislation are often very great, but in view of the end to be attained, the profession in the different States should not be discouraged, and should work persistently and patiently until the thing is done. We have had a hard time of it in New York State. It took years of persistent effort on the part of our State and County Societies to bring the standard where it is. Every year new enemies have arisen, but so far our efforts have been crowned with success. As a result, our colleges have better and higher standards, our students are better qualified for examinations, and altogether we are recruiting our ranks with first-class men. This experience will be repeated wherever the examining are separated from the teaching bodies, and should be an encouragement for other States who may be merely making experiments in this line, or have such measures merely on trial.

It is fair to say in this connection that the profession of the United States owes a great deal to the Illinois State Board of Health for the consistent, straightforward missionary work in this line that it has done for several years past. We congratulate it accordingly, and more especially in view of the present admirable showing of progress made so manifest in its last report, to which we are so glad to refer, and for which we are so happy to give proper credit.

THE CONTROL OF PROSTITUTION.

The control of prostitution has been so often discussed from the social and medical sides that we are beginning to become quite familiar with the standard arguments pro and con. But while we muse, the fire burns. We talk of what should be done, but, alas! it is only in the subjunctive sense. Many experiments have been tried under a licensing system and all have failed. The acknowledged difficulty has been that only one side of the question has been attacked. The other has seemingly been impossible of approach with a view to the reasonable remedy. One sex is warred against, while the other equally important factor is let alone. The absurdity of the measure is apparent on its face. The female is corralled, registered, restricted, mulcted, and blackmailed, while the necessary partner in the evil-doing goes unmolested as to personal liberty, untrammelled in the exercise of so-called individual rights, free from inspection or question, and is an unrestricted disseminator of foul disease. These are all patent facts which everyone admits who has studied the subject even in the most superficial manner. This, in truth, is one of the main reasons why all laws aiming to control prostitution are ineffective. They become essentially one-sided and consequently inoperative. The evil is said to be a necessary one, and the subject being also an unpleasant one for discussion we are inclined to seek others which are more congenial to refined tastes and more likely to produce tangible results. No attempt has been yet made to control the male element in the equation, and it is not probable that there will be. And even in such a possible event the evil is likely to go on, although in a less open manner, for no law has yet been found to effectually legislate against immorality based upon perverted or diseased appetite. The liquor laws show this. The individual resents the attempt as a blow at his personal rights, and retaliates in circumventing the law by acts which were not dreamed of before. The prostitution laws also show as much in the increase of clandestinism in direct proportion to the apparent decrease of legitimized wrong. All this proves the complexity and many-sided aspects of the question.

The most perfected inspection that can be at present instituted cannot eradicate venereal diseases, even allowing that both parties are equally subjected to such supervision. No absolute guarantee can be given against infection in persons exposed to the chances of the frequently concealed, the dangerously incubating, and the often unrecognized contaminating influences. The certificate has only an approximative value, which may be entirely annihilated by the first new comer, who may be the means of transmitting the virus to the next, even in the intervals of the most frequent official inspections. When such facts become more widely known, they may be of themselves an element of control of this form of licentiousness which will be more powerful than law and more effectual than any other form of appeal. It is here that the medical profession can do good in a quiet, admonitory, and telling manner.

The foregoing remarks are suggested by the report on the subject of prostitution in another column, and as a preliminary for heartily endorsing the sentiments on chastity so well expressed by some of the gentlemen who took part in the discussion. It is on this line, also, that the physician can do good work. Let him on all suitable occasions combat the idea that sexual indulgence is necessary for health, and maintain with equal truth and force that chastity is perfectly compatible with full vigor, that it conduces to strength of mind and body, is the foundation of the purest morality, is the most effectual safeguard against any form of prostitution, and the only and absolute answer to the possibility of controlling this widespread vice. If every physician could be a missionary in his own field and would inculcate such a doctrine, especially among the young, the effect upon the coming generation would be beyond calculation for good, and would prepare the way for that perfected education in morals which would strike at the very root of the evil.

USELESS MEDICAL CHARITIES.

The *Medical Times and Hospital Gazette* points out that thousands of dollars are yearly devoted to the maintenance of institutions that serve no other purpose than to advertise those connected with them. The profession certainly ought to frown down the frantic appeals for more funds made by such so called charities.

The promiscuous distribution of glowing circulars, and the soliciting of alms by benefit performances, coupled with the vulgar display of names composing so-called medical boards and boards of managers, ought to stamp an institution as undeserving lay support and professional countenance. When reputable hospitals make occasional appeals they do so in a dignified way and without ostentatiously parading the names of their medical boards before the public.

Our British contemporary has seen the starting and working of a few of these medical charities. The *modus operandi* is very simple. A F.R.C.S., or M.D., having failed to obtain an appointment at a hospital of standing, and finding patients do not troop into his consulting-room, as a last desperate resource takes a dilapidated house in a main thoroughfare and christens it a hospital. His baker, greengrocer, tailor, and other tradesmen, to whom he is over head and ears in debt, form a desirable committee of management, and nothing further need be done but to advertise the place, send out circulars and begging letters to the aristocracy, and judiciously place a large number of collecting-boxes.

But while enterprises of this character seem to do fairly well in England, they are apt to get into financial difficulties in our country. The gullable public is then asked to subscribe, in order to enable this "medical board" to pay off debts. This would, indeed, be medical charity of a novel kind.

Let us therefore draw the line sharply between charities undertaken for the benefit of the deserving poor and concerns propped up for the glory of ambitious nonentities.

Medical Association of Georgia.—The Forty-fifth Annual Session of the Medical Association of Georgia will meet in Atlanta, Ga., on April 18th, 19th, and 20th.

To Be Cholera Inspector Again at Hamburg.—The Government has ordered Surgeon Woodward to go back to Hamburg as cholera inspector for next summer.

News of the Week.

The Indian Medical Congress.—The proposal to have a Medical Congress in India was considered at a meeting of the Council of the Calcutta Medical Society on January 24th, when it was decided that an "Indian Medical Congress" shall be held in Calcutta at the beginning of January, 1895. The preliminary arrangements were discussed and a general plan sketched out. It was decided that in each province local secretaries, native as well as European, should be asked to co operate with the Calcutta secretaries, and it was further decided that the sections into which the Congress should be divided should be: 1. Medicine, including Pathology. 2. Surgery. 3. Obstetrics and Diseases of Women and Children. 4. Public Health. 5. Medico legal Medicine and allied subjects. Further details will be given in a future issue. It was decided that the Congress should be widely advertised, and that all medical men practising in every part of the world, but especially in India and the East, should be invited to take part in it and submit papers to be read in the different sections.—*Indian Medical Gazette*, Calcutta.

The Ohio State Medical Society is nearing the half-century of its existence. It will hold its forty-ninth session at Zanesville, May 16th, 17th, and 18th. The secretary reports an unusually good programme in preparation.

Not Quintuplets.—Dr. J. T. Deimar, of Manorville, Pa., writes: "I wish to correct a statement made in a recent issue of your journal concerning the birth of quintuplets by Mrs. Daniel Rosenberger. The woman lives but a few miles distant, so I can state positively that such event never took place. The family made application to the township for aid. One neighbor woman heard of their application, and in repeating it to another woman, added that there were five small children in the family of the Rosenbergers. The story gained by repetition until it was reported throughout the county that there were five children at one birth. Many amusing incidents were caused by the circulation of the story. The manager of a Pittsburg museum, in the hope of securing the children for his house, came to Kittanning, and drove ten miles over muddy roads, to find the story untrue. Several reporters and an agent for children's food were also disappointed."

For the Prevention of Blindness in the State of Ohio.—A bill for the prevention of blindness in Ohio has become a law. It has the following provisions: "Should one or both eyes of an infant become inflamed or swollen, or show any unnatural discharge at any time within ten days after its birth, it shall be the duty of the midwife, nurse, or relative having charge of such infant to report in writing, within six hours, to the physician in attendance upon the family, or, in the absence of an attending physician, to the health officer of the city, village, or township in which the infant is living at that time, or, in case there is no such officer, to some practitioner of medicine legally qualified to practise in the State of Ohio, the fact that such inflammation, swelling, or unnatural discharge exists. Any failure to comply with the provisions of this act shall be punished by a fine of not less than ten dollars, nor more than one hundred dollars, or imprisonment for not less than thirty days, nor more than six months, or both fine and imprisonment. This act shall take effect and be in force from and after its passage."

Typhoid in Buffalo, N. Y.—Typhoid fever is almost epidemic in Buffalo to date. An order has been issued to all the public schools to either filter or boil the drinking-water or shut off the supply from the children.

The Roman Fever.—In view of the number of foreign medical men who will visit Rome this season, the following, from Dr. David Young (*Medical Magazine*, March, 1894), may be of interest: "During the same period, *i.e.*, from the beginning of 1882 till the end of 1893, the number of deaths among English and American visitors to Rome was one hundred and ninety-four, or about sixteen deaths every year. Of these seventeen were due to typhoid fever, ten to gastritis and enteritis, and six to malaria. Even if the typhoid cases are bracketed with those registered as gastritis and enteritis, this would only give a total of twenty-seven cases in twelve years, or a little over two deaths from this cause every year; while, as regards malarial fevers, the mortality has been six for the same period, or an average of one death every two years. It is therefore matter for genuine surprise to the medical practitioners in Rome that so much is said of a deadly fever prevalent at all seasons in the city, and yet never appearing as a factor in the mortality except as of malarial or typhoid origin; and these have been shown to affect, to only a very slight degree, English and American strangers who reside in or happen to be passing through Rome."

The Ohio Pharmacy Law.—The pharmacists of Ohio are in an angry mood over the attempts now being made by interested parties in that State to secure the passage of a bill in the State Legislature to repeal the Pharmacy Act of Ohio. While not a repeal bill in the exact sense of the term, the measure, if it becomes law, will permit any one who can claim five years' experience in a drug store to register as a pharmacist or as an assistant pharmacist, as the case may be, without any examination whatsoever. The Ohio State Pharmaceutical Association is working vigorously in the matter, and has sent out a circular to all of its members requesting them to write personal letters to their Senators and use every influence possible to oppose the bill.

Prize of the Medical Society of the County of New York.—The Committee on Prize Essays of the County Medical Society beg leave to call the attention of the members of the Society to the annual prize offered by it, together with the rules governing the award of the prize. 1. The prize shall consist of a gold medal, 150 grammes in weight, which shall bear upon one side the seal of the Society, and on the other the following: Awarded as the annual prize by the Medical Society of the County of New York to ——— for an essay on ———. 2. The essays shall be handed to the Committee on Prize Essays on or before October 1st in each year. 3. Each essay shall be accompanied by a sealed envelope containing the name and address of the author, and bearing on the outside the motto which is inscribed upon the essay. 4.

The writer of each essay is expected to present his dissertation in a plain and distinct handwriting, and with the pages bound in book form. 5. Any clew by which the authorship of an essay is made known to the committee will debar such an essay from competition. 6. Other things being equal, preference will be given to essays which exhibit original work on the part of the author. 7. The Society does not consider itself as approving the doctrines contained in any of the essays to which the prize may be adjudged; and, in case of publication of a successful essay, the author shall be considered bound to print the above in connection therewith. 8. The selection of the subject upon which to write will be left open to the competitors, but will be restricted to the field of what are called the departments of medical study. 9. The Society will return to unsuccessful competitors their essays, if called for within six months after the award has been made 10. The committee is empowered not to award a prize in case none of the essays are worthy thereof. 11. The prize is restricted to members of the Medical Society of the County of New York. 12. The Society reserves to itself the right to require that the essay for which a prize is awarded shall be read before the Society previous to being placed at the disposal of the author.

Committee { Joseph D. Bryant, M.D., Virgil P. Gibney, M.D., Græme M. Hammond, M.D.

German Surgical Congress.—The twenty third congress of the German Surgical Society will be held in Berlin from April 18th to 21st, instead of at Eastertide, as usual, so as not to clash with the International Congress in Rome. Among other subjects on the programme are the following addresses: Professor Bruns, of Tübingen, "The Results of Tuberculous Inflammation of the Hip joint under Conservative Treatment;" Professor Küster, of Marburg, "Early Operation in Osteomyelitis;" and Professor von Bardeleben, of Berlin, "Early Movement of Fractured Limbs with Special Reference to the Lower Extremity." A report on the results of a collective investigation on anæsthetics will be presented by Professor Gurlt.

The International Medical Congress.—The *Lancet's* correspondent writes: "The Central Committee has come to a final decision as to the labors of the Congress and the order in which they shall succeed each other. The inauguration will be solemnized in presence of His Majesty the King of Italy on March 29th. There will be many festive demonstrations, public and private, including a grand reception in the Capitol, the sculpture gallery of which will be thrown open and its *chefs-d'œuvre* of statuary, as on similar occasions, placed *en évidence* under the electric light, while the Platea Archæologica (the Forum, the House of the Vestals, the Sacred Way, the Basilica of Constantine, the Arch of Titus, the Colosseum, the Arch of Constantine, and the Palace of the Cæsars) will be brilliantly illuminated. Thirty-two nations will be officially represented at the Congress by seventy three delegates; 344 scientific "corsi" (lectureships) will also send representatives. The communications hitherto announced for (possible) reading and discussion are 2,080. Among the chief personages in the science and practice of the profession there is hardly one —Italian or non Italian—who has not intimated his intention of coming to Rome. The official business will be overtaken by April 5th, as already stated. I may add that among the excursions in contemplation after the rising of the Congress few will equal in attractiveness the three now being organized by the Balneological Society of Naples. Incidentally meant to show the members the rich resources possessed by the Neapolitan Riviera in mineral waters, the excursions will cover ground in which archæology has alighted on its most precious treasure trove, besides affording views of mountain, insular, and coast scenery unrivalled on the Mediterranean littoral."

At Last Accounts the Hospital Sunday Fund this year was $10,000. Special efforts are being made to bring the amount up to the average.

Death of Dr. A. C. Stanard.—Dr. A. C. Stanard died at the New York Hospital, on the 19th inst., of peritonitis following an operation for acute appendicitis. He had suffered with chronic relapsing appendicitis for two or three years. He was of New England parentage, and aged twenty-nine. Educated at the University of Michigan and at the Harvard Medical School, he came to New York in 1889 and served the full term on the Second Surgical Division at the New York Hospital. After finishing his hospital service he was made Attending Gynecologist to the New York Dispensary and Instructor in Gynecology at the Post Graduate Medical School. He was a member of the Academy of Medicine, the County Medical Society, Harvard Medical Society, New York Hospital Alumni Association, and various other medical societies, as well as of the University Athletic and other social clubs. Dr. Stanard was a man of sterling worth, devoted to the profession which he loved, and in which he had already attained an enviable reputation. A firm friend, an ardent and enthusiastic worker, his loss will be severely felt by all who knew him.

Professor Billroth as an Operator.—The general public not unnaturally assume that a great surgeon is necessarily a most skilful operator, a mistake not infrequently made by the profession also. Ingenuity, however, and boldness in devising operations are very different attributes from the manipulative skill, decision, and tact required to carry them out. Professor Billroth united the two sets of qualities in a very conspicuous manner. Yet it was always the guiding intellect rather than the manual dexterity which impressed itself on the spectator. Truth to say in the actual performance of an important operation Billroth showed no very marked superiority over his fellow surgeons. He avoided any show of brilliancy or flourish, went steadily to work, erred, if at all, on the side of slowness, and was neither more nor less discomposed by any complication or untoward event than anyone else. The finish of his operative work was rather the result of his immense experience than of any remarkable aptitude. Nevertheless, as an operator he must be held to have justly earned a very high place.

Errata.—Dr. Hemingway wishes to make the following corrections to his recent article: Minor Surgical Gynecology in footnote 2, page 349, should be in footnote 3, and credited to Dr. P. F. Mundé. Encyclopædia of Obstetrics and Gynecology in footnote 3 should be Grandin. Editor.

Reviews and Notices of Books.

Reference Handbook of the Medical Sciences. Vol. IX. Supplement. Edited by Albert H. Buck, M.D. New York: William Wood & Co. 1893.

The present is a period of enormous activity in all branches of medical research. The above volume cannot fail to be of great service to the large body of physicians who desire to keep posted upon medical matters, but who find it impossible to refer to the multitude of journals and reports in which the results of research are recorded. The supplementary volume of the "Reference Handbook" is an admirably arranged and fairly exhaustive epitome of the progress that has been made in medical science during the years that have elapsed since the publication of the original work. It is but a few years since the appearance of the latter, and the size and character of the present volume are a striking indication of what has been accomplished in the meantime.

The greatest advances have been made in experimental medicine, and naturally the Supplement is especially rich in material from this department.

Yet the practical aims of the book have evidently been kept constantly in mind. Much space is given to accounts of new drugs. In many cases the real utility of these has not yet been determined, but of all of them satisfactory descriptions are given, and when possible an attempt has been made to estimate their value.

Moreover, the field of general therapeutics and hygiene has been carefully gone over, and the most interesting and important work that has been been done in this department is described under the appropriate headings.

The nervous system, its anatomy, physiology, and pathology, receive much consideration.

The scope of the work is very wide, covering, as it does, the entire range of medicine. The various articles are for the most part short enough to be of use even to busy practitioners, yet thorough enough to escape the charge of being superficial. In fact, one is throughout impressed by the thoroughness with which the various collaborators have executed their tasks.

On the whole, the work is one of great value, and is sure to be appreciated by all who aim to keep up with modern medical science.

Notes on Some Cases of Nervous Disease Treated with Brown-Séquard's Orchitic Fluid. (Wood & Whiting, *Lancet*, February 3, 1894.)

The writers treated by the above method twenty-three cases, among which were four cases of tabes, two of Friedreich's ataxy, one of ataxic paraplegia, and several cases of disseminated sclerosis and paralysis agitans. They give their results with this plan of treatment in the following words: "Of twenty-three cases of chronic nervous disease, one only showed any improvement in physical condition during this course of treatment, and, as has before been pointed out, the cause of this improvement must be looked upon as open to considerable question. We have obtained no results such as would justify further trial of this method of treatment."

The Medical Student's Manual of Chemistry. By R. A. Witthaus, A.M., M.D., Professor of Chemistry and Physics in the University of the City of New York; Professor of Chemistry and Toxicology in the University of Vermont; Member of the Chemical Societies of Paris and Berlin; Member of the American Chemical Society, etc. Fourth Edition. New York: William Wood & Co. 1893.

Ten years to the month and almost to the day from the date of the first edition's preface, that to the fourth was written, and in it the author states that he has much extended and in great part rewritten that portion of the work treating of the chemistry of the carbon compounds. Those alkaloids whose molecular structure has been determined have been properly classified according to the lines followed in previous editions, and other changes calculated to improve the character of this popular manual have been made, bringing the work well up to the advances of the times. One appendix gives the orthography and pronunciation of terms, while another presents tables of solubilities. A full index of 21 pages completes a well-arranged volume, well printed on good paper, and attractively bound in red muslin.

A Clinical Text book of Medical Diagnosis for Physicians and Students, Based on the most Recent Methods of Examination. By Oswald Vierordt, M.D., Professor of Medicine at Heidelberg University. Authorized translation with additions, by Francis H. Stuart, A.M., M.D., Member Medical Society, Kings County, N. Y., etc. Third Revised Edition. 8vo, pp. 700. Philadelphia: W. B. Saunders. 1894.

This work has become deservedly popular with progressive practitioners, and stands in the foremost rank of its class. Its compact form, admirable arrangement, and thoroughly scientific character are qualities which will commend themselves to every reader. As a result of long experience as a teacher, the distinguished author has learned to appreciate their actual wants, and with a conscientious thoroughness of detail succeeds in giving a distinctive picture of different diseases that is not only admirably clear, but distinctly practical. His system is such that the reader is taken by easy steps through the knowledge of the anatomy and physiology of the apparatus under consideration, to the abnormal deviations of function and structure which constitute disease, and then to that differential analysis of significant symptoms which is the high art in medicine. The painstaking and rational examination of the patient are the essential elements of this study, and tend to infuse in the student an enthusiasm for necessary details which is so essential to real success in practice. It is a good book in every way, and merits a wide patronage.

An American Text-book of Gynecology, Medical and Surgical, for Practitioners and Students. By Henry T. Byford, M.D., J. M. Baldy, M.D., Edwin B. Cragin, M.D., J. H. Etheridge, M.D., William Goodell, M.D., Howard A. Kelly, M.D., Florian Krug, M.D., E. E. Montgomery, M.D., William R. Pryor, M.D., George M. Tuttle, M.D. Edited by J. M. Baldy, M.D. 8vo, pp. 713. Philadelphia: W. H. Saunders. 1894.

This work is on the same plan as that of the American Text-book on Surgery, being the composite production of a number of specialists, with a corresponding distributive responsibility as to individual authorship. While this gives the readers a condensed and digested presentation of the views of the different writers, the whole responsibility of their effectiveness and consistency is vested with the editor. This has its advantages in the matter of practical condensation of the views of active workers in a given branch, but not infrequently the teachings lose their force and directness for the want of individual recommendation. When, however, we view the work as the joint product of a so-called stock company of experts, we must take it on its general merits as such. Thus far, certainly, it is a great success. It is practical from beginning to end. Its descriptions of conditions, its recommendations for treatment, and above all the necessary technique of different operations, are clearly and admirably presented. The divisions and arrangement of the work are excellent, the general style is terse and intelligible, and the numerous and excellent illustrations are admirably placed and judiciously selected. As a text-book it is well up to the most advanced views of the day, and embodies all the essential points of advanced American gynecology. It is destined to make and hold a place in gynecological literature which will be peculiarly its own. As a book for students it has a serious drawback in the matter of its restriction to subscription sale.

Laboratory Guide in Analysis and Toxicology. By R. A. Witthaus, M.D., Professor of Chemistry in the University Medical College, New York, etc. Third Edition. New York: William Wood & Co. 1893.

This is the well-known book of the author, who has added in the present edition a system of qualitative analysis. The manual has interleaved blank pages for note-taking, and is an ideal guide for medical students.

Information for Nurses in Home and Hospital. By Martin W. Curran, Graduate of the Mills Training School, Bellevue Hospital. 12mo, pp. 323. New York: J. H. Vail & Co. 1893.

Books of this kind are now so numerous that additions to the list can practically add nothing new. The task narrows itself down to the art of clear presentation of well-known facts. In this respect Mr. Curran has succeeded measurably well The book has a particularly attractive appearance. We confess that we have learned considerable from reading it, though it is written by a layman for his associates in the department of nursing. The author, too, seems to have an unusually accurate perception of the relative position of physician and nurse in the conduct of a case. A good vocabulary of medical terms is appended.

Healthy Hospitals: Observations on Some Points Connected with Hospital Construction. By Sir Douglas Galton, Late Royal Engineers, K.C.B., etc. 8vo, pp. 287. Oxford: The Clarendon Press. 1893.

This is a valuable contribution to the literature of a most important subject. The eminence in engineering circles of Sir Douglas Galton would alone determine its merit. After a brief introduction into the origin of hospitals, he defines them as places, "not only for the reception and cure of the sick poor, ... but also as technical schools in which the medical student must learn his profession, and as experimental workshops in which the matured physician or surgeon carries on scientific research." We commend this definition both for its accuracy and liberality of spirit.

Succeeding chapters treat technically of site, ventilation, warming, lighting, ward arrangement, etc. Special chapters are devoted to the consideration of institutions for special purposes, as lying-in hospitals, children's hospitals, etc. While the subject-matter is largely technical it is presented in a clear style, and its meaning is clear to any intelligent person. The book contains plans of, and references to, the construction of many notable hospitals in England and on the Continent, and our local New York Hospital is not overlooked. We commend Sir Douglas Galton's book to all builders of hospitals.

Text-book of Normal Histology. By George A. Piersol, M.D., Professor of Anatomy in the University of Pennsylvania. 8vo, pp. xviii., 439. Philadelphia: J. B. Lippincott Co. 1893.

Among recent works on histology we have a preference for the one before us. Only essentials are given, and controversial matter is barely alluded to. As an introduction to more complete manuals this volume will take high rank. Many of the cuts are originals, and most of them are very well executed. The mechanical execution of the work is decidedly good. It should prove a popular text-book with students.

Asiatic Cholera Its Genesis, Etiological Factors, Clinical History, Pathology, and Treatment. By John A. Benson, Professor of Physiology and Associate Chief of the Department of Clinical Medicine, College of Physicians and Surgeons of Chicago, Ill.; Member American Anthropometric Society of America; American Medico Psychological Society; of the Chicago Pathological Society. 16mo, pp. 248. Chicago: The J. Harrison White Co. 1893.

Asiatic Cholera. Its History, Pathology, and Modern Treatment. By A. J. Wall, M.D, London, Fellow of the Royal College of Surgeons of England; of the Medical Staff of H. M. Indian Army (Retired List). London: H. K. Lewis. 1893.

Both of these works are elementary treatises on a disease that was expected to reach our shores last summer. In ordinary times the physician takes but a lukewarm interest in cholera. But when the scourge becomes epidemic a voluminous literature at once springs up. The volumes before us present nothing new. But what is generally accepted as "sound doctrine" in relation to cholera is concisely stated.

Surgery: A Manual for Students and Practitioners. By Bern B. Gallaudet, M.D., Demonstrator of Anatomy and Clinical Lecturer on Surgery, College Physicians and Surgeons, New York, and Charles N. Dixon Jones, B.S., M.D., Fellow New York Academy of Medicine, etc. 12mo, pp. 301. Philadelphia: Lea Brothers & Co.

This little volume is one of the regular student's Quiz Series, and is an exceptionally good one, especially in the chapters treating of abdominal operations It covers the general field of practical surgery very effectively and intelligently, and is a model of its kind.

The Diseases of Childhood (Medical). By H. Bryan Donkin, M.D. Oxon., F.R.C.P., Physician to the Westminster Hospital and to the East London Hospital for Children at Shadwell; Joint Lecturer on Medicine and Clinical Medicine at Westminster Medical School. New York: William Wood & Co. 1893.

The work here presented to the medical public is attractively gotten up, and deals with the clinical aspects of children's diseases, subdivided into six sections covering the alimentary, febrile, nervous, respiratory, circulatory, and general disorders.

Mental and skin affections have been omitted, and very little is said on the subject of the skin manifestations of syphilis. It is praiseworthy in the author that he has preferred to leave out chapters on variola and some other maladies, rather than discuss questions in which he admits his own experience has been inconsiderable. With these omissions, however, the work cannot be considered complete, but one which must be supplemented by a treatise dealing with these diseases by themselves. A useful appendix is introduced between Sections III. and IV., giving the period of incubation and contagiousness of the infectious diseases. In diphtheria the author prefers early tracheotomy to incubation, "in view of the probable evil effects of constant inhalation of air which has passed over the diseased naso-pharynx." Little reliance is placed upon belladonna in the treatment of enuresis. In the enumeration of remedies for noma, bismuth packing as recommended by McGuire, and in whose hands it seemed to act so well, is not mentioned. The book is largely the record of the practical clinical experience of the author, and is clearly intended for those who have already some knowledge of the complaints of infancy and childhood. It will thus prove of value to advanced students as well as to practitioners.

A Guide to the Study of Gynecology. By Marie J. Mergler, M.D., Professor of Gynecology at the Northwestern University Woman's Medical School; Attending Surgeon at the Woman's Hospital, of Chicago; Gynecologist at the Wesley Hospital, etc. Chicago. 1893.

This little work of one hundred and sixty pages is practically a short synopsis of lectures on the diseases of women, or a mind-refreshing cursory review which may enable students to dispense with note taking at the lectures. It was originally intended for the author's own students, but might prove helpful to any preparing for examinations.

Diseases of the Skin. A Practical Treatise for the Use of Students and Practitioners. By James Nevius Hyde, A.M., M.D., Professor of Skin and Venereal Diseases, Rush Medical College, Chicago: Dermatologist to the Michael Reese Hospital, Chicago: one of the Physicians for Diseases of the Skin to the Presbyterian Hospital, Chicago; and Consulting Dermatologist to the Chicago Hospital for Women and Children. Third Edition, thoroughly revised and enlarged. Philadelphia: Lea Brothers & Co. 1893.

It is gratifying to know that dermatological investigation renders necessary the frequent rewriting of text-books on this important subject. The labor required for such revision, correction, and addition is in a measure understood when we learn that no less than thirty five new diseases are touched upon, with more or less fulness of detail, in the present edition of Dr. Hyde's excellent work. Five new and original plates and twenty-two wood-cuts have been added, to the marked improvement of the illustrations.

Some of the important changes noted are in the chapters on tuberculosis and lupus, while among the newly considered disorders are pityriasis rubra, pilaris, keratosis follicularis, pemphigus vegetans, Savill's disease, acanthosis nigricans, alopecia follicularis, etc. The volume reaches eight hundred pages, and in its new form commends itself more than ever to those requiring a treatise on the skin well up to the times.

A Medical Handbook for the Use of Practitioners and Students. By R. S. Aitchinson, M.B.C., M.F.R.C.P. With numerous Illustrations. London: Charles Griffin & Co. (Limited). Philadelphia: J. B. Lippincott Co. 1893.

This little handbook is divided into seventeen chapters, and although it numbers three hundred and forty-seven pages, it is so light that it can be easily slipped into the pocket to be used for quick reference. It is a most valuable book for a busy practitioner having no immediate access to a large and voluminous text-book. One objection, rather fine type, will greatly improve the book. The illustrations, especially from page 128 to 131, inclusive, are very good and practical.

Essentials of Minor Surgery. Bandaging and Venereal Diseases. Arranged in the Form of Questions and Answers. Prepared especially for Students of Medicine. By Edward Martin, A.M., M.D. Seventy-eight Illustrations. Philadelphia: W. B. Saunders. 1893.

This is one of the most practical books that one can desire, not only for students but for the general practitioner. The illustrations are neat and clear. The book deserves to be carefully studied, and will be found full of practical hints.

Technique d'Électrothérapie. Par G. Gautier. J. Larat Maloine, Éditeur, 91 Boulevard Saint-Germain, Paris.

This volume is the beginning of a series, a sort of compendium on electro therapeutics, giving the modern views and current information concerning the uses of electricity in medicine.

A Text-book of Physiological Chemistry. By Olaf Hammersten, Professor of Medicine and Physical Chemistry in the University of Upsala. Authorized translation from the second Swedish edition, and from the Author's enlarged and revised German edition, by John A. Mandel. First Edition. New York: John Wiley & Sons. 1893.

The work is divided into fifteen chapters, and deals with the Protein Substances, Animal Cell, Blood, Chyle, Lymph Transudations and Exudations, Liver, Digestion, Tissues of the Connective Substance, Muscle, Brain, and Nerves, Organs of Generation, Milk, the Skin and its Secretions, Urine, the Exchange of Material. It is clearly written and gives full details for both student and specialist. It should be well received by all desiring complete information on this subject. We welcome the translation as a thorough adaptation of that most earnest and brilliant scholar, Professor Hammersten.

The Art of Living in Australia. Together with Three Hundred Australian Cookery Recipes and Accessory Kitchen Information. By Mrs. H. Wicken, Lecturer on Cookery to the Technical College, Sydney. By Philip E. Muskett, Late Surgeon to the Sydney Hospital; formerly Surgeon Superintendent to the New South Wales Government; Medical Superintendent, Quarantine Station, Sydney, etc. 4to, pp. 431. London, Edinburgh, Glasgow, Melbourne, Sydney, and New York: Eyre & Spottiswoode.

This is a practical treatise on every-day hygiene and dietetics, with special reference to the physical and climatic peculiarities of Australia. In view of the semi tropical climate, the author strongly urges the more general use of fish and fruit rather than meat as an article of daily food, and gives much sensible advice of general application. Incidentally, considerable interesting information is given regarding the history and possibilities of the fisheries and the wine-growing industry of Australia.

A Text book of Physiology. By M. Foster, M.A., LL.D., F.R.S. Fifth American, from the Fifth English, Edition. Thoroughly revised, with Notes, Additions, and 316 Illustrations. Pp. 1,083. Philadelphia: Lea Brothers & Co. 1893.

A Text book of Physiology. By M. Foster, M.A., M.D., LL.D., F.R.S. With Illustrations. Sixth Edition. Part I., comprising Book I. Blood, The Tissues of Movement, The Vascular Mechanism. New York and London: Macmillan & Co. 1893.

Many of our readers will remember a little red book of eight hundred pages which gave them many a bad quarter of an hour in student days. It was "Foster's Physiology," and this small work has grown into a large octavo of eleven hundred pages Life is short, but the study of life gets longer and longer. Coincident with the issue of the fifth American edition we get Part I. of the sixth English edition.

"Foster's Physiology" is classic, and deserves to be. It has lost none of its authority, none of its merits, or its faults. The style is lucid and logical; it teaches the student to think; but its discursiveness at times is unnecessary, especially for the learner, and often a long process of inductive reasoning might be cut out and the reader given simply the conclusion. But "Foster's Physiology" has done a great deal of good, it is mental food and discipline as well as physiology. We are glad to see that it is still in the front of standard text-books. One who reads it can but feel that here is a man indeed, and not merely a book-maker.

A Practical Treatise on Materia Medica and Therapeutics. By Roberts Bartholow, A.M., M.D., LL.D, Professor of Materia Medica, General Therapeutics, and Hygiene, Jefferson Medical College, Pennsylvania. Eighth Edition. 8vo, pp. 820. New York: D. Appleton & Co. 1893.

The large number of students and practitioners who have looked upon this book as an authority on the subject of which it treats will be pleased to welcome a new edition from their favorite author. The peculiarities of the work are such as give to the teachings of Professor Bartholow a value which is thoroughly practical and impress the reader with the fact that the author is a thorough optimist in therapeutics and a firm believer in the power of properly selected drugs for given conditions. The work as a whole has been newly edited, to conform to the many changes in formulæ and remedies made by the decennial revision of the United States Pharmacopœia. Many new drugs are necessarily added, some of which are proprie-

tary in character, but the author explains his course regarding the latter that the demand for exact information regarding them is so great that no book on materia medica would be complete without reference to them. With this proposition many of his readers will agree. The metric system of weights and measures has been adopted, but the equivalents in the Troy measure are also given.

The Treatment of Cutaneous Malignant Epithelioma ta (Cancers). By A. R. Robinson, M.B., F.R.C P. & S. Edin., Professor of Dermatology in the New York Polyclinic, Attending Physician to the New York Cancer Hospital, etc. New York: The International Journal of Surgery Co.

This is a reproduction of two papers published in the *International Journal of Surgery*, 1892. The author is not a believer in the parasitic theory. He shows that secondary tumors owe their origin exclusively to epithelia derived originally from the primary tumor. For certain growths he advocates caustic pastes.

Myxœdema and the Effects of Climate on the Disease. By A. Marius Wilson, M.D. Pp. 36. London: Scientific Press. 1894.

In this brief monograph the author outlines the features of myxœdema as at present understood. In regard to climate he claims that the course of the disease is much slower in the warm countries, and that the abnormal sensations are those of heat instead of cold. Clinical histories illustrate the latter points.

A System of Genito-urinary Diseases, Syphilology, and Dermatology. By various Authors. Edited by Prince A. Morrow, A.M., M.D., Clinical Professor of Genito-urinary Diseases; formerly Lecturer on Dermatology in the University of the City of New York; Surgeon to Charity Hospital, etc. With Illustrations. In three Volumes. Vol. II., Syphilology. New York: D. Appleton & Co. 1893.

The scheme of copartnership in book production—especially in works of such pretension—seems to be simply an outcome of the onward march of science and its achievements. No one man could have written this treatise upon syphilis within any period of time at all proportionate to that consumed by the twenty-three contributors in making it ready for the printer's hands. No one author could have treated all the subjects equally well, and it seems eminently proper that the eye specialist should write upon syphilis as it implicates the eye tissues, the neurologist upon that of the nervous system, the orthopedic surgeon upon syphilis of the bones. The prevailing tendency stamped upon every chapter is the avoidance of unimportant details, and the evident intention that each subject shall be the exponent of the author's views and personal experience, has resulted in a striking freedom from bibliographical references.

It is thus a practical working-book of to-day rather than a history of syphilis of the past, and all the errors that have been connected with it.

We deem it unfortunate that a chapter on chancroid was included in this volume, for although it occupies but forty-seven of the nine hundred pages, it not only mars the monographic feature, but would seem to give a certain warrant for the belief that in some way chancroid is part of the syphilitic process. In those beginning the study of syphilis it is essential that no erroneous views are formed which will have to be unlearned, and for this reason when we read on the first page of Dr. Sach's article "that syphilis of the nervous system appears not infrequently after soft chancre without the customary secondary eruptions," we feel that a note of warning is necessary to guard against a fifty years' step backward. Let it be taught that the infection sore need not of necessity be indurated, if you will, that there may be a mixed infection, but do not give the impression that these primary lesions are chancroids. The illustrations, numerous and excellent as they are, for the most part, might still be improved upon—a few pictures of hereditary syphilis not quite so hideously hopeless as that of Plate XIX. could be introduced. Dr. Bull has illustrated his chapter with an instructive plate of eye affections, and two plates of fundus appearances taken mostly from Jules and Loring's works.

In Fig. 7 of Dr. Allen's plate of syphilitic tongue affections the references *a* and *b* should either have been omitted in the explanation or added in the engraving. The various skin lesions of syphilis are well illustrated in the chapter written by the editor himself.

Visceral syphilis has been ably treated by Dr. Councilman. Exact knowledge concerning many phases of internal syphilis has been most scanty until recent times, and although much yet remains to be learned, this chapter gives a good account of what is now known, and anyone will be repaid in reading "Syphilis of the Lungs." Throughout, the individual work of each writer gives the impression of having been carefully done, and with the desire to make it worthy of the scope and aim of the system to which this volume belongs.

A Manual of Diseases of the Nervous System. By W. R. Gowers, M.D., F.R.C.P., F.R.S. Second edition, Revised and Enlarged. Vol. II., Diseases of the Brain and Cranial Nerves, General and Functional Diseases of the Nervous System. With 182 Illustrations. 8vo, pp. 1,069. Philadelphia: P. Blakiston & Co.

The American publishers issued the first edition of this work in one volume, but the present is in two, making a work of seventeen hundred pages. The second volume has about one hundred additional pages.

The thoroughness and encyclopædic character of Dr. Gowers's work is well known. In reviewing the first edition we enumerated its merits and gave to it unstinted praise. We may be pardoned now for calling attention to some of the book's defects.

The anatomical parts are practically unchanged, and give no suggestion to the reader of the remarkable advances made in this direction during the past four years. The illustrations, though intelligently conceived, are very badly executed. The spinal-cord diagrams greatly need revision.

Dr. Gowers is evidently not a master of pathology, hence his descriptions of pathological changes and his classifications are lacking in clearness and definiteness. We doubt if neurology will long accept such old fashioned chapters as those on myelitis, encephalitis, and insular sclerosis. He has made no addition of importance to the subjects of the pathology of paralysis agitans or of epilepsy, despite recent important contributions to these diseases. He still ignores practically the existence of such a malady as neurasthenia in any of its types, and he gives us nothing regarding the traumatic neuroses. We hardly see the necessity of embodying in a systematic treatise the experience of a single case and giving it a new name; yet we find descriptions of tetanoid chorea, senile paraplegia, and chronic cerebritis, based on these extremely scant data. Such chapters make unnecessary padding to a book already very voluminous.

We should say that the present edition of this work was not nearly as closely in touch with modern neurology as was the first, particularly as regards its pathology, anatomy, and nosology.

Yet it is a remarkable clinical manual, showing learning, research, practical neurological experience, and an industry that is simply marvellous. In justice to the English publishers we ought to say that their edition is a much better printed one, though the illustrations are equally bad in each.

A Dress Reform Advocate asserts that a man should not marry a lady whose waist measures less than twenty-five inches.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, February 22, 1894.

MALCOLM MCLEAN, M.D., CHAIRMAN.

Presentation of Specimens.—DR. PAUL F. MUNDÉ presented the following specimens: 1. Five cases of tubal pregnancy removed by laparotomy; recovery. 2. A large double pyosalpinx; recovery. 3. Uterus with appendages and subperitoneal fibroid, removed per vaginam for epithelioma of the corporeal endometrium; recurrence. 4 Uterus with appendages removed entire by laparotomy for sarcoma of the body; recovery. 5. Abscess of the ovary; perforation into the large intestine; recovery.

Remarking upon the cases of tubal pregnancy, Dr. Mundé said that in the second one both the patient and her husband mentioned the fact that the orgasm was very unusual, a point which had been regarded by some authors as indicating conception. Interruption of the connection had been suggested to be one reason for tubal pregnancy, but this had not occurred in this case. Four of the five cases of tubal pregnancy had been seen within six weeks, the other within a year. In only one did he have any doubt as to the diagnosis after operation.

Referring to the case of double pyosalpinx, Dr. Mundé said that where both tubes were affected, whether free or adherent, he would remove them, but if only one were affected, and this were adherent, he thought it would be proper to drain per vaginam. Referring to vaginal hysterectomy, the speaker said this mode of operating had lost its charms for him; that he would rather do abdominal hysterectomy. In his fourth case, after removing the uterus and its appendages, he drained through the vagina, which he would not do again in a clean operation, as he regarded drainage unnecessary under such circumstances. This case was an interesting one because of starvation due to a cause which became quite clear only at the autopsy. The patient was a maiden lady, forty-nine years of age, who had had difficulty with swallowing since a girl. By some it was thought to be due to hysteria. It was only after peculiar efforts in the erect posture that she could get the food to pass from the œsophagus into the stomach. After the operation the family physician attempted to feed her through a stomach-tube, but later it became evident that he did not always succeed in introducing this farther than a large diverticulum of the œsophagus near its lower extremity; that food had collected here, remained undigested, and caused a great deal of distress. As already stated, death ensued from starvation in what had promised to be a very favorable case.

Referring to the fifth case, abscess of the ovary with perforation into the large intestine, Dr. Mundé thought it somewhat surprising how some women would go about months and years with abscess of the ovary, no accident resulting, while in others serious consequences resulted from rupture, perforation of the gut, etc.

The Chairman, DR. MCLEAN, thought it very possible that the development of the fœtus in tubal pregnancy might be arrested, while that of the envelops went on. In treatment by electricity some held that while the fœtus might thus be killed, the danger did not cease, for the envelops and vessels might go on increasing in size.

DR. MUNDÉ thought it an interesting question whether intraligamentous effusion of blood was always due to ectopic pregnancy. He had always taken the negative view but was becoming doubtful.

Modified Fritch Irrigation Tube—Modified Uterine Dilator.—DR. AGUSTIN H. GOELET presented the instruments which will be described in a later issue of the MEDICAL RECORD.

Umbilical Cord with a True Knot.—DR. S. MARX presented an umbilical cord with a true knot, the first case of the kind which he had ever seen. This labor and all previous ones of this woman had been complicated. The attending physician had temporized, the woman had been long in labor, the cord was prolapsed and could not be replaced, the child's life was in jeopardy, so that Dr. Marx thought it necessary to perform accouchement forcé. In ten minutes the child was on the bed, but unfortunately was still-born. The cord, besides having a true knot, was unusually long, forty-one inches.

Uncomplicated Ovariotomy—Septic Peritonitis from Unknown Cause.—DR. MUNDÉ related a case of laparotomy for removal of a simple multilocular ovarian tumor the size of a child's head; the operation a simple one—no adhesions encountered, time not more than twenty-five minutes—yet for some unaccountable reason the woman got up an intense acute septic peritonitis and died about the second day. All antiseptic and aseptic precautions had been taken, and inquiry failed to reveal any source of infection. Within twenty-four hours after the operation the temperature had risen to 103° F., the pulse to 150; the mind was perturbed. He therefore reopened the abdomen and found evidences of intense acute peritonitis, unquestionably septic in nature. The abdomen was washed out, but the case pursued its fatal course. Nothing was found at the autopsy to indicate the source of infection. The speaker referred to a similar case which had occurred in the practice of Dr. Thomas.

DR. GOELET mentioned a case of Cæsarean section in which the patient died without apparent cause unless from obscure shock.

Notes on Pruritus during Pregnancy and the Puerperium.—DR. H. C. COE sent a brief paper on this subject, which was read by the Secretary, Dr. Jarman. Of the many minor troubles from which women suffered during pregnancy and the puerperium few were more distressing than local pruritus. Physicians were apt to underrate such minor troubles and dismiss the patient with the cold comfort that this was one of the annoyances of pregnancy which must be patiently endured as it would come to an end in the course of time, or else they prescribed a common ointment and made no effort to discover the cause of the trouble.

We were driven to the conclusion, the author thought, that even local pruritus was mainly a dermato-neurosis dependent upon the general nervous condition. One of his patients, eight months pregnant, had pruritus of the external genitals which had been attributed to a discharge from the cervix, but douching and other local treatment did no good until the general nutrition had been improved. Concentrated, irritating urine might cause pruritus, but it had sometimes been given the credit when the state of the general nervous system was the real cause. This was illustrated in a case in which the urine was of high specific gravity, acid, scanty; one day only ten ounces were passed, but it contained no albumin nor casts, nor were there any other symptoms pointing to an organic lesion. Increasing the quantity of urine and local applications failed to give relief; exacerbations of the pruritus continued until after delivery and then disappeared. It was clearly a case of general neurosis depending directly upon pregnancy, and therefore treatment had been without avail.

Puerperal dermatitis was almost always of the form of acute urticaria. A case of this kind was that of a woman who after delivery got up a urticaria with some fever, there being no apparent cause. In a few days the patient was as well as ever, and he was disposed to regard the urticaria as due to some error in diet, until he learned that it had appeared the next morning after great excitement. In another case there was almost complete suppression of the lochia, which, however, had no bad odor. He irrigated the uterus and the flow reappeared. Two days later the temperature rose to 102° F., the patient had an eruption supposed to be measles, which proved to be urticaria, the fever and eruption gradually declined

after forty eight hours, septic trouble was excluded, and no cause of the symptoms could be found except nervousness. The accompanying headache, nervousness, and reduction of the lochia in these cases of urticaria during the puerperium might lead one to suspect sepsis and cause alarm.

The prognosis during pregnancy was doubtful. As to treatment, where the general nervous system was at fault he thought one should avoid strong lotions locally and drugs for internal use which tended only to further irritate the disturbed stomach. Locally one might apply carbolic acid in some form. Salicylic acid, which had been recommended by French writers for internal use, had not given Dr. Coe satisfaction. The kidneys and bowels should be kept regular, nervousness allayed, cooling lotions applied during the puerperium, diet regulated.

A First Experience.—Dr. Marx said that about the first case which he had on entering private practice was one of pruritus vulvæ in a pregnant woman who employed another physician because Dr. Marx failed to cure her. In some cases the pruritus of pregnancy was only a continuation of what had existed before; some of the vulva were due to parasites, others to a true neurosis. He had seen several of the latter kind permanently relieved by the application of the constant current, negative pole, to the affected part. A solution of nitrate of silver or menthol was also useful in this class. He questioned whether those cases reported in Dr. Coe's paper as having partial suppression of the lochia and some fever were entirely neurotic; there might have been some systemic infection.

Dr. Herman Collver thought a number of cases of pruritus vulvæ during pregnancy and the puerperium resulted from ulceration of the external os or small ulcerated patches in the vagina. He had seen applications of nitrate of silver set up so much pain as to almost induce abortion, and cautioned against the use of strong solutions to the cervix during pregnancy. Lukewarm injections with peroxide of hydrogen were advisable, also solutions of nitrate of silver if tried cautiously. Pruritus vulvæ after labor was probably due to infection. The discharge need not necessarily have an odor in sepsis. If the discharge were sufficiently irritating to produce pruritus, one should wash out the uterus, preferably with a weak solution of bichloride of mercury.

In old syphilitic patients a discharge was apt to be irritating whether it were or were not septic. Parasitic cases required special treatment, of course.

Thick Vaginal Secretion and Pruritus.—Dr. McLean said that in some of the worst cases of pruritus seen by him there was, in the folds of the vagina, a thick, "boiled-rice" secretion which seemed to be the exciting factor.

Dr. Goelet said the remedy which had given him the best results was the constant douche with Thiersch's solution, afterward dusting the parts with powdered boracic acid.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PUBLIC HEALTH.

Stated Meeting, March 7, 1894.

J. West Roosevelt, M.D., Chairman.

Objects of the Section.—The Chairman, Dr. Roosevelt, stated some of the objects of this Section. It might not be generally understood that one of its purposes was to form a connecting link between the profession and the general public; that it was proper to bring before it for discussion all matters of interest both to the laity and physicians. The only action which the Section could take upon such matters, aside from discussing them, was to refer them to the Academy when requested to do so by a majority vote.

The Question of State Regulation of Prostitution.—Aaron M. Powell, Esq., read the paper. When Sanger wrote of prostitution, in 1858, the number of women living as prostitutes in the city of New York, from information given by the then Superintendent of Police and from other sources, was estimated to be six thousand. In a paper prepared for the World's Congress of Social Purity, held at Chicago, 1893, Mr. Gerry had stated that he and Superintendent of Police Byrnes had compared notes with the same results, estimating the present number of prostitutes in New York City at forty thousand. But prostitution was not an affair of one sex only. How numerous were the male prostitutes could be estimated only approximately. Dr. Sanger, writing of the liability to infection, etc., had said that if a prostitute received but one visitor a day she would be unable to pay her board and dress as she was required to do; even two visitors daily was a low estimate, and four was not an unreasonably large one. If, then, we accepted as substantially accurate the estimate of Mr. Gerry and Superintendent Byrnes, we could multiply forty thousand by four, and certainly not exceed the number of male prostitutes, or one hundred and sixty thousand. Large as this number appeared, there was no reason to believe that New York was more immoral than other large American cities. The evil was wide-spread, and had been since remotest times. It had been, and continued to be, a great destroyer of physical health and of the finer qualities of womanhood and manhood, and also involved great economic waste. Dr. Sanger had estimated that the weekly income of each courtesan could not be less than eleven dollars; in the more expensive houses it averaged not less than thirty or forty dollars. During his time, therefore, men gave directly to prostitutes over three million dollars annually, and if the number in New York to-day were forty thousand, the sum would amount to more than twenty million dollars, and if the average weekly income of prostitutes was twenty dollars, as it probably was, the sum would mount up to forty million dollars yearly. Add to this the expense of wine and liquors involved in visits to houses of prostitution, and the annual expense on prostitution to-day in the city of New York would probably be not less than sixty five million dollars.

Of course, of an evil of such magnitude, attended by consequences so grave, the State should take cognizance. The Old-World method had been for many years to license it. This plan was based upon the assumption that vice was a necessity for man, and that a certain class of women had to be set apart to minister to his lust; based upon a double standard of morals, one for woman, another for man. Experience had abundantly proven that this one sided plan of regulation, which licensed a few women to pursue prostitution as a trade, subjecting them to compulsory registration, while letting their miscellaneous male consorts go free to disseminate disease at will, and always leaving a large army of clandestine prostitutes without any surveillance whatever, was worse than a failure, for it served to stimulate rather than to check prostitution.

Law in itself was an educator, and might educate downward instead of upward. License gave prostitutes a legal status, yet made slaves of its victims, prepared pitfalls for young men, and perverted the true function of government, which was, according to Gladstone, to make it easy to do right and difficult to do wrong.

St. Louis's Experience with License.—America, he said, had had but a single noteworthy trial of licensed prostitution. By a trick a law was passed through the legislature of Missouri, in 1870, which gave licensed prostitution to St. Louis, and after four years of this system the law was repealed. The petition for its repeal was signed by many hundreds of laymen, lawyers, doctors, and ministers. Mr. Powell analyzed the statistics regarding the results of these four years of license, and thought they plainly demonstrated that the result was not what had been anticipated by its better-minded advocates, for clandestine prostitution was increased, the number of professed prostitutes also increased, venereal

diseases were also more widely spread. He dwelt upon St. Louis's experiment because of a disposition, even at this time, to quote it in favor of the license method, as had recently been done by the chief of police of Cleveland, who had assumed the right to establish a registration system in that city.

Experience in Cleveland.—Mr. Powell had been credibly informed that the result of the recent introduction of the system of registration into Cleveland by the chief of police was to give boldness to those who were registered, as they felt that the police would not interfere, and to demoralize citizens who previously might have led a chaste life. He had been informed that the examinations as to disease were made by medical students, perhaps weekly, for which they received one dollar and gave a certificate of health. These certificates of health were worse than useless. Even eminent physicians had acknowledged inability to say positively from such an examination that the subject was free from venereal disease. Moreover, if free at the time of the examination, the certificate would afford no assurance against infection by the next visitor.

Having referred to the experience with license on the continent of Europe, where, as the author stated, they were about to abandon it as a failure, a review was given of its operation in England, and finally in India. The statistics given by Dr. Nevins, of Liverpool, were accepted as authoritative, and they showed an increase of prostitution and of venereal disease during the years of license in England, up to the repeal of the law in 1886, and also in India, where the object of the system was especially to lessen venereal disease among the soldiers. At different places the number of prostitutes provided for the soldiers varied from about one for seventeen men, one for nine men, and one for three men. Yet venereal disease was more prevalent among the soldiers provided with the greatest number of prostitutes.

Social vice had been made an important factor in police misrule, of which New York was an example. Spasmodic efforts to shut it out were usually made with an ulterior purpose. The police tolerated, and even protected, the brothel for a consideration. Allied with the saloon and gambling room, the brothel had become not only a source of disease and moral degradation, but also of political corruption. The State could not do, and ought not to be expected to do, impossible things; it could do nothing effectively except as law was vitalized by public opinion. But it ought on no account to give prostitution a legal status and recognized right to be. Its aim should be the utmost restraint possible, and ultimate evolution of man's nature out of the thraldom of lust. It ought to be fair and just alike to women and men. It had hitherto dealt too exclusively with women. It rightfully interdicted the brothel as it did the gambling den; it prescribed punishment for the keeper of a house of public debauchery, and also for those who let the house for such a purpose. It ought to rigorously punish the incitement of minors of every sex to debauchery, and especially procurism or trafficking in girlhood. Its penalties should include imprisonment as well as fines, for fines in most cases were readily paid and acted only as a tax upon vice with a minimum of restraint. Especially for the proprietress and the landlord, imprisonment alone would deter.

The physician had greater power to mould public opinion in this matter than any other members of the community, especially concerning the sanitary aspect of prostitution, and could thus lead up to wholesome repressive laws in the interests of morality and health. There was still a popular notion that for men vice was a necessity, and that young men must sow their wild oats. But what was morally wrong could not be physiologically right.

The author would that physicians everywhere might be quickened to declare, with the late Sir Andrew Clark, that immorality was not a necessity, and that chastity for all was a human possibility.

Improbable Statistics.—Before calling for discussion Dr. Roosevelt remarked that it seemed hardly conceivable that the number of prostitutes in New York City, given by the two gentlemen quoted in the paper, could be correct, for forty thousand meant one in twenty of the female population.

Destructive of the Foundations of Government.—Dr. D. B. St John Roosa was not sure, considering his training from childhood, that he was in a position to express an impartial opinion upon the subject of State regulation of prostitution, but he found himself unable to believe that there was any necessity for municipal establishment of a set of people to minister to that which was not necessary, which was vicious, and destructive of the foundations of the country. While he did not claim to be an expert in venereal diseases, yet he had had experience in a large municipal hospital, and he did not believe any doctor, whatever his experience, would say that he could positively state, from a physical examination of prostitutes, that they were free from disease, and if they could not make a positive statement upon the question it would be of no value. Never give authority into the hands of officials anywhere which could easily be abused. The evil consequences in this city from such a system could hardly be imagined; but add to the political power which the authorities now possessed, that which might come from giving into the hands of two or three hundred physicians the right to pronounce for a fee, after examination from week to week, upon the health of prostitutes, and he thought Sodom and Gomorrah ought to have something to say.

It had been placed before our minds that the police authorities had a right to condone evil of any kind. But Dr. Roosa asserted that they had no moral right to condone any legal offence, and we had no more cause to submit to it than to their entering our houses and taking away our property. They were put there to be the defenders of the law, and if the laws were wrong the right remedy was for the people to amend them.

Active Suppression.—Dr. Emma Blackwell referred to the example of Glasgow, in proof of the fact that the police could, if they would, do much in the way of active suppression of prostitution.

Dr. A. F. Currier deprecated the evil of prostitution and the suggestion of giving it what appeared like a legal standing, and also confirmed the view expressed by others that a physical examination by young physicians, or even by experts, would be of little value as security against infection, even if made after the departure of each visitor—an impossible thing when it was remembered that in such an event four examinations or more might be required daily. He also denounced the practice of the police condoning the evil for political purposes.

Chastity Possible for All.—Dr. Andrew H. Smith would like an expression of opinion from the Academy, which would be imitated by the medical profession throughout the length and breadth of the land, that chastity was possible and wholesome, in no way detrimental, but in every way promotive of health and human happiness. If the public could be impressed with the fact that this was the view of the entire medical profession, prostitution itself would accompany the belief that it was a necessity into oblivion.

Dr. C. T. Adams thought the question which concerned physicians chiefly was whether venereal diseases could be diagnosed by a physical examination, and if so, it seemed to him that as long as prostitution existed a law calling for compulsory examination would tend to check the spread of such diseases.

Dr. Lesser expressed the opinion that a system of prostitution avoided a greater evil, the seduction of innocent girls.

Mr. Powell closed the discussion. He earnestly desired that the medical profession would impress upon the public at every opportunity the view expressed by Dr. A. H. Smith, that chastity was good for the health as well as for the morals, and was possible for all men.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

MULTIPLICATION OF SOCIETIES, GENERAL AND SPECIAL—JEALOUSIES AMONG THEM—THE DERMATOLOGICAL SOCIETY AND THE PROPOSAL TO FORM A SECOND—A STORM IN A TEACUP—BRITISH INSTITUTE OF PREVENTIVE MEDICINE—OPPOSITION OF FADDISTS—REV. MR. HAWEIS AS ONE—RECENT LECTURES—LONDON BAKEHOUSES—DEATH OF MR. BERNARD HOLT.

LONDON, March 3, 1894.

I HAVE previously alluded to the recent increase in the number of medical societies here. Notwithstanding this development our number is trifling compared with yours. But we seem rather to run in grooves. Of course there are numerous branches of the British Medical Association, but we do not reckon them. In the country they serve a certain purpose, bringing together a few neighbors, more or less disposed to meet. In London the districts meet and the branch has its dinner. This, too, is an important function of country branches; a president of one told me once that he presided over an assembly of two, three, or four at the local hotel, when the bodily refreshments were well attended to—and nothing else. Another confessed that he and one other had often constituted a meeting.

Some of the societies of specialists have done good work, the ophthalmological, for example. So have the obstetrical and the gynecological, concerning the jealousy between which I have said a word or two. A still more jealous set seem the two laryngological, for the second has established itself. A friend of mine asked one of the most interested in the second what was the necessity of it, and was gravely told that it was for "the respectable laryngologists" to meet! Asked if none of the members of the first were respectable, he "would not go so far as to say that," but it was not select enough. Asked if any one of the most respectable had held aloof from both, he was obliged to admit the fact. It really seems a pity that there should be so much waste of superfluous energy which might be more usefully directed into strictly scientific channels.

The dermatologists, too, have their little difficulties about societies. There has been for a long time a sort of clinical club of dermatologists, restricted to thirty members, who met from time to time to chat over cases exhibited at the meeting. These gentlemen called themselves the Dermatological Society, as they had a full right to do, there being no other body entitled to the name. As their proceedings were quite private, no transactions being issued and no reporters invited, there was no occasion for non-members to recognize their existence. They had their friendly clinical chat ten times a year. Lately, however, it was proposed to form a real Dermatological Society, which could be called British, or by any other distinctive name. Then the harmless club, or rather some of the thirty, became suddenly alive to its privilege, and a "state of tension" was produced between some of the old club and the proposers of the new society. Why, it is hard to say, and Mr. Jonathan Hutchinson seems to think so too, for he lent his support to the new movement, although a prominent member of the old. Then followed a funny little "storm in a teacup."

Mr. Malcolm Morris, in an address, enumerated, as the British dermatologists, the prominent members of the old society, but left out Mr. Hutchinson's name—he, as I have said, having countenanced the new one, and so, it was averred, having given offence. A good deal of talk went on about this little cabal, which somehow found its way into the *Medical Press and Circular*, which rated the thirty rather severely. It was hardly worth while, for Mr. Morris's address would have attracted no attention but for the attack of the promoters of the new society. No one takes Mr. Morris very seriously, either from the side of science or courtesy, and Mr. Hutchinson has no need of the praise of any dermatologist. In fact, he wrote a letter to your contemporary deprecating the tone of the correspondence that had been published and the state of tension among dermatologists, as well as pointing out that, in his opinion, there was room for the new society and no occasion for rivalry. So many spicy stories have been circulated over dinner-tables and at other meetings that it may be doubted whether Mr. Hutchinson's authority will be able to control the ill-feeling engendered. He will certainly experience the usual difficulty of "running with the hare and holding with the hounds." The best thing would be for the club to enlarge its bounds and take in the new society. One well-supported society would surely be enough.

The British Medical Institute of Preventive Medicine is fast becoming a solid fact. Money and a site have been secured. The anti vaccinationists are accordingly enraged, and adopting their usual tactics of circulating statements of a grossly inaccurate character. The Rev. Mr. Haweis is a V. P. of one of the faddists' societies, and has joined in this effort to thwart scientific research. I do not know Mr. Haweis personally, but I hope he is a more pleasant acquaintance to those who do than his public actions would lead some to suppose. He always strikes me as very much of a quack. From the pronunciation of his name in a manner that the letters would suggest to no Englishman, and his conspicuous yellow carriage, up to his sensational lectures on queer topics in his pulpit—all smacks of clap-trap. Then his literary productions—well, perhaps I have been unfortunate in my selection, so will withhold my opinion. But in this matter of the Institute it is too bad that a clergyman who has achieved notoriety should, in the endeavor to enhance it, make accusations which he ought to know are not true. When a man is ignorant on a subject he is not called upon to express an opinion. If his love of notoriety impels him to do so, he is bound to be sure of his facts. This is especially true of a clergyman when charging others with motives of which he would himself be ashamed. But some parsons have so high an opinion of their own acquirements that they consider no subject is beyond their ken. Medicine and science to such seem "milk for babes," and they shower upon others modern euphemisms, for "I am Sir Oracle, and when I ope my mouth let no dog bark."

At the Medical Society of London the Lettsomian Lectures are now concluded. The Milroy Lectures at the College of Physicians have also been given, and their treatment is exciting some comment. The horrible condition of some London bakehouses has again been brought before the public. St. George's Hospital is about to have a statue of John Hunter. The movement can hardly be called premature.

Mr. Bernard Holt, whose name must be well known to your readers from his writings on "Stricture of the Urethra," died on Tuesday last, aged seventy-seven. He had long held a prominent position in London, and was surgeon, and subsequently consulting surgeon, to the Westminster Hospital. He was a lover of horses, and largely interested in a West-End livery stable.

Migranine.—Under this name Overlach (*Deutsche Med. Woch.*, No. 47, 1893) describes the properties of a combination of antipyrin with caffeine and citric acid. He considers it a chemical combination of the three substances, and, after five years' experience of its action in cases of migraine and other forms of headache, he has come to regard it as an almost infallible cure, even in the most obstinate cases. It is useful whether given in the premonitory stage or after the headache has fully developed, and it is seldom that more than one dose is required. The dose is 1.1 gr., to be taken dissolved in water. This quantity contains only 0.09 gr. of caffeine, or one-sixth of the maximal dose of this substance. It is recommended that the patient rest a while after taking the drug, especially in cases of severe migraine.

A HYPOTHETICAL QUESTION.

To the Editor of the Medical Record.

Sir: In the complexity of experience a principle that under certain circumstances shall be a correct rule of action may fail to guide us under different surroundings. There are certain great moral principles which we are compelled to think of as unchangeable. But the rules derived from them are in constant flux.

It is not, then, useless or improper at any time to search among the foundations of any law or custom to know whether it is based upon principles in harmony with the state of society as at present constituted, or whether it is a relic of other conditions now subject to revision. It is not subversive to morality or social order to make such inquiries. If the foundations are based upon principles at present in force and furnishing a logical basis for what they support, investigation can only strengthen the intellectual structure.

If the study shall reveal weaknesses and rottenness, it surely cannot be beneficial to society to conceal the fact, even if it be at some minor point. Gradual repair, the result of foresight, is better than revolution, the result of wilful blindness.

Let us suppose a not impossible case. An arrest has been made of a murderer of the stamp of Guiteau, Prendergast, or Vaillant. The evidence shows that he is a crank, a chronic criminal of inherited criminal tendencies, a constant menace to society. Any expert could pick out his photograph among a hundred others as belonging to the type. He is sent, after a longer or shorter trial, to the gallows or to the insane asylum.

About the same time a woman built after Lombroso's type of female degeneracy finds that she is pregnant by this man. What little foresight she has tells her that loss of any respect she may have would follow the birth of the child, and that she would be unable to support herself with the child clinging to her.

We physicians who have more carefully studied sociology and inheritance can predicate much more. The child might die early in an asylum or from neglect, perhaps the most fortunate result. In this case there is simply left the disgrace of the mother and the effect upon her health, and the time and expense of her accouchement, which are probably directly or indirectly paid by society, then and thereafter. If the child should live it would inherit no tendencies but those of its father and mother. It might grow up no worse than a street Arab or a wharf rat. Probably, however, if a girl she would become a strumpet; if a boy, a thief.

This result, as inevitable as other laws of nature, is now recognized by society. Attempts have been made to counteract the evil. Institutions for the training of such boys, like the Elmira Reformatory, have been established. The indiscriminate cohabitation of criminals said to have been allowed in English jails, would now be looked upon as reprehensible social policy. It is proposed after the third conviction for crime to castrate the criminal. Statistics and essays are being multiplied to arouse society to the immanence of the evil, that some remedy may be found. In these days of train-wreckers and anarchists, that the problem of inherited vice is one of the most important to our increasingly interdependent society is evident.

To return to our hypothetical case. This woman finding herself four or five weeks over time consults me, who have attended the family at times. I find that she is probably pregnant, but I tell her that I am not an abortionist, and if she persist in her importunities, I very properly order her out of the room. What shall she do? The only legal course is to remain passive and trust to society to care for her and her little one.

But she may go to one of the many professed abortionists, who for what money she can raise will introduce a dirty wire through the os uteri, perhaps gonorrheal, and produce abortion for her, either with or without peritonitis. Since these people are not disturbed unless one of their cases should die, one would think that in self-protection they would have already learned surgical cleanliness. But working, as they must, in the dark and underhandedly, with no literature, without the possibility of exchange of thought on this subject, in only the rarest cases ever having a medical education, it is not strange that the risk to life in consulting them is very great.

It is noteworthy that when an abortionist is arrested, it is the death of the mother, not the destruction of the fœtus, that entails danger of punishment. Does this not show that while we still style the production of fœtal death murder, all common judgment unites with the results of the study of development in recognizing the human fœtus at six weeks as not yet a human being.

Or our supposititious case may get a hint from some friend, and, after repeated attempts, herself get some instrument past the internal os. This is illegal and a State-prison offence; but she knows, and everybody knows, that no woman since the adoption of the United States Constitution was ever arrested for it. The only risk she runs is the same as do her married sisters in producing peritonitis, cellulitis, salpingitis, and the train of diseases that swell our gynecological clinics.

There remains but one very improbable, but still possible, hypothesis. She may find a regular, capable physician who, realizing what is portended to herself and to society by letting nature take its course, will perform the operation for her. We will suppose that he had talked the case over with a brother practitioner—that he had done the operation antiseptically as he would curette the uterus—that he had put the woman to bed as after any other operation, visited her till a week was passed, and dismissed her entirely well.

Sometime later this physician is arrested, the facts all come out in court, and according to law he is sentenced to ten years in State prison. In what way is society benefited by his incarceration? Is it impossible to conceive a time in the evolution of society when the operation in such a case shall be made mandatory?

Respectfully,

F. W. Higgins, M.D.

Cortland, N. Y., February 28, 1894.

TURKEY AND PTOMAÏNE.

To the Editor of the Medical Record.

Sir: Since your recent publication of my account of what seemed to be a case of "Atropia Poisoning from Eating Turkey," I have received a number of communications suggesting various other explanations. The one of a "ptomaïne-poisoning," from a partial decomposition of the flesh which was at that time in exactly the right stage for the production of these animal alkaloids, seems the most probable one in view of the arguments brought forth, the recently published experience of L. C. Osmun, M.D., with fish-poisoning, and later experiments carried out by myself with the same turkey meat. In my account of the experience sent to the Medical Record I stated that the "rest of the turkey was burned," but in fact I had left a few small pieces, cut from the portions I had originally examined, which I had put aside in a moderately cool place. After writing that article I did not get time to give further thought to the matter for over a week. But then it occurred to me to repeat the experiments more in detail, to find, if possible, whether the offending alkaloid was contained in the skin, the brown meat, or the white meat, or in all equally. On looking at the pieces I had preserved, I was disappointed to find they had undergone such a degree of putrefaction that the odor was very offensive. But in spite of this I made three separate infusions of the parts mentioned, and at different times instilled some of each in one eye only. I was at first surprised and disgusted to find that in neither case was the slightest effect produced on the pupil, nor yet when the infusions were all mixed together. This result I now find goes far toward proving the ptomaïne theory. For experiments on de-

composing flesh have shown that these atropia simulating animal alkaloids are only originated at a particular stage of decomposition, while a still further advance in the process decomposes them and renders them inert.

I wish here to acknowledge my, perhaps, excusable error in diagnosis while expressing my thanks for the suggestions and information so kindly offered by letter and in print, for the clearing up of this peculiar case.

H. H. SEELYE, M D.

AMHERST, MASS.

BLOODLESS AMPUTATION AT HIP-JOINT.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I enclose Dr. Brashear's description of his method of hip amputation, which is published in an appendix to Mott's "Velpeau's Surgery."

If Dr. Buechner has not seen it, I think that it should add some difficulty to the retention by him of the shade of doubt that he expresses in his letter to you, which was published in your issue of January 27, 1894, to observe that this description was written before the resurrection which claims his faith.

One who did not believe (as I most assuredly do believe) that Dr. Brashear performed the operation as stated, might give him the credit that his priority deserves, when he has described so minutely the method almost universally preferred to-day, with modifications which cannot affect its essential character, to suit individual operators. I was at the pains to correct some misstatements on this subject in a short letter that appeared in your journal, July 18, 1891. This letter indicated the popular diffusion of Dr. Brashear's fame. He was given credit for his work by Dr. Paul F. Eve, both in his "Remarkable Cases in Surgery" and in his lectures for many years on surgery in Nashville, Tenn.; and I am told that Dr. Valentine Mott, Sr., reviewed the case annually in his lectures at Bellevue in *ante-bellum* days.

I have made some efforts, in the way of private correspondence with the authors of some modern representative works on surgery, to secure for this backwoods surgeon the acknowledgment that is due his advanced judgment, but without avail. Hence I announce that I have forwarded to *The Lancet* also a copy of Dr. Brashear's letter, in order to give it the widest diffusion possible in our tongue.

While I appreciate the expedients of Dr. Wyeth to the extent of not only having done everying in my power to have them introduced into our service, but also agreeing heartily with a recent reviewer, who calls this method for the prevention of hemorrhage "one of the greatest improvements of modern surgery," yet I am willing to join forces with Dr. Buechner, if he is willing "to go still farther back." I can perceive no valid objection to the longer journey, and I doubt if Anglo-Saxon justice will deprive a pioneer of his deserved fame, either for having been forgotten or for not having been known.

Very respectfully,

W. F. ARNOLD, M.D.,
Passed Assistant Surgeon,
United States Navy.

UNITED STATES COAST DEFENCE VESSEL MONTEREY,
MARE ISLAND, CAL., February 14, 1894.

[LETTER FROM DR. BRASHEAR TO DR. P. S. TOWNSEND.]

PHILADELPHIA, August 13, 1846.

MY DEAR SIR: In conformity to promise, I now give a brief statement of the operation which I performed in Bardstown, Ky., in August, 1806, on the hip-joint.

The subject was a boy, seventeen years of age. Without assigning the causes which led to the necessity of the operation, the same was, after consultation with Drs. Harrison and Goodlet, conducted in manner following, first premising that, in absence of any knowledge of an established mode for this operation, a common-sense reasoning as to its safety and facility alone dictated the manner of performing it. Therefore an operation of the thigh in the ordinary manner was determined on, as remote from the hip-joint as circumstances might justify (in this case about mid-thigh). The amputation was performed, and the arteries secured.

The next step was to make an incision to and from the lower end of the bone, externally, over the great trochanter to the head of the bone and upper part of the socket. The dissection of the bone from the surrounding muscles was simple and safe, by keeping the edge of the knife resting against the bone. The bone being disengaged from its integuments at its lower extremity, was then turned at a right angle from the body, so as to give every facility in the operation to separate the capsular ligament and remove the head from its socket. After the operation, nothing more than ordinary dressings were used, and in the course of a short time the patient removed to St. Louis, where he was living within a few years past.

I am, very respectfully,

WALTER BRASHEAR.

EX-CONFEDERATES AND PENSION SURGEONS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In your issue of February 24, 1894, page 244, you state in substance that the Commissioner of Pensions has ruled that no ex-Confederate surgeon is eligible to serve on Pension Board, etc., which is taken up and commented on in high dudgeon by the Texas surgeons.

Now, if our section of the United States is any criterion to go by, it is far from true. In Kansas City, Mo., to-day, the Pension Board is composed of two ex Confederates, the third not being old enough to have been one. In Kansas City, to-day also, there are at least a dozen regular reputable physicians of the Democratic persuasion, who served their three and four years in the Union army during the rebellion. Hence there can be no excuse, from a political stand-point that reputable physicians were not attainable. We hear that all over Missouri the same condition exists—that the ex-Confederates take preference. We can easily understand that where there are both ex-Union and ex-Confederates, that naturally the ex Union surgeon should take preference in such a responsible and, I may say, delicate place. But why, in our locality, the ex-Union is totally ignored, can only be answered by the politician. I am of the impression that no such ruling has ever been made by Judge Lochren.

Yours, etc.,

EX UNION.

KANSAS CITY, MO., February 26, 1894.

A STOP OVER EN ROUTE FOR DELEGATES TO THE INTERNATIONAL CONGRESS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The time chosen for the meeting of the International Medical Congress of 1894 will unfortunately prevent most, if not all, of the Anglo-American physicians practising at the winter stations of the Riviera from attending. Many of us have still very vivid recollections of the delightful time we had on the occasion of our visit to the Washington Congress of 1887, of the unbounded kindness shown to us, and of the charming trip from Washington to Niagara, provided for us by the liberal hospitality of our *confrères* of the United States, which will ever live in the memory of those who had the privilege of taking part in it. Our attendance in Rome being impossible, we are unable to arrange any return for the favors received in 1887, and it occurs to one whether it would not be possible to organize a meeting at Nice (the capital of the Alpes-Maritimes), or some other station on the Riviera, of those of our American brethren who will be passing through it *en route* from Rome to Paris on their return from the Congress.

It is extremely probable that many will take this opportunity of making a first acquaintance with the beauties of this coast, then looking its very best, and it would

be, I am sure, a very great pleasure to their *confrères* of this region if, by combined action, they could do anything in their power to make a visit to these sunny climes as agreeable to them as possible.

May I beg the great favor of your inserting this letter, which I have made as short as possible, in an early number of your valuable paper, with an earnest request that the Secretary, or other officer who is responsible for the arrangements of the visit of the American members to Rome, will have the kindness to communicate with me his ideas on the subject; on receipt of which I will place myself in correspondence with the English and American physicians practising on the Riviera in order to arrange combination of action. I am, sir,

Your obedient servant,

S. S. ASHMORE-NOAKES, M.D.

5 PROMENADE DES ANGLAIS, NICE, FRANCE,
February 28, 1894.

New Instruments.

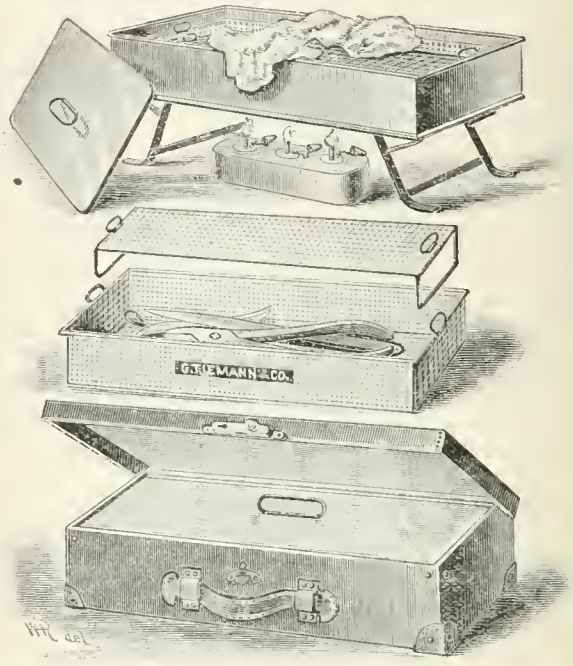
AN ASEPTIC OBSTETRICAL INSTRUMENTARIUM.

BY GUSTAV SEELIGMANN, M.D.,

NEW YORK.

A PUBLICATION by Professor G. Winter, of Olshausen's Clinic, in Berlin, in the *Deutsche Medizin. Wochenschrift*, No. 4, 1894, in which he describes a new aseptic case for obstetrical use, induces me to briefly note an apparatus which I have had constructed for the same purpose and have been using for some time.

Winter lays down three postulates as required in such an apparatus: 1. All instruments which come in immediate contact with the patient must be absolutely sterile. 2. The obstetrician should be provided with all instruments and utensils which may possibly be used in obstetrical operations, including Cæsarean section, laparotomy for abdominal gestation, etc. 3. The instruments should be so arranged that only those probably necessary in any given case need be carried. All of these requirements are perfectly fulfilled in the arrangement which I have devised, and I venture to say, far more conveniently than in the rather cumbersome apparatus of Professor Winter.



I attempted, in my first essays, to provide a suitable sterilizer for obstetrical purposes, to include in one case all the instruments, utensils, drugs, etc., which may be required, but soon found such an arrangement to be unpractical.

In the first place, a satchel containing the twenty or thirty articles necessary besides the instruments, is far too large and too heavy. In the second place, each of these numerous articles must be provided with an appropriate place in the satchel; this complicates the arrangement enormously and creates a third difficulty, namely, that any deviation from the arrangement provided by the instrument-maker is virtually impossible, and the physician is compelled to forego the advantages which he may derive from modifications suggested by his experience.

It seems to me better not to bind the obstetrician too closely to any given armamentarium. Even the very elaborate Winter's apparatus fails to provide for certain instruments which American physicians would not like to be deprived of, as, for instance, a set of Simon's specula, side levers for examination and suture of the cervix in cases of laceration, a colpeurynter or Barnes's dilator, a long probe pointed knife for cervix incisions (though for my part I prefer a scissors for that purpose), axis traction forceps, etc. Kelly's pad and Clover's crutch are considered almost necessities in private practice, and they, of course, cannot be packed into any such case as Professor Winter's. We would therefore, in any case, be compelled to carry along an additional satchel to our patients.

These considerations have led me to modify my former apparatus in the direction of greater simplicity. I make now use of two satchels. One is an ordinary leather portmanteau into which everything except instruments is put, such as all rubber articles, drugs, chloroform inhaler, etc. The other satchel contains the instruments and is at the same time the sterilizer.

A stout leather cover, 17½ × 8½ inches, with handle and lock on one side, encloses a close fitting box of thin nickel-plated copper. The latter contains a similar close-fitting tray of galvanized wire gauze, on the floor of which the stand for the box lies folded, occupying a minimum of space. An alcohol lamp with three burners serves as the source of heat. The apparatus in working order is seen in the figure. The instruments may be

wrapped in clean sterilized towels, or a simple contrivance made by stitching a strip of linen down the middle of a sheet of the same stuff may be employed.

The instruments to be used are taken from their linen cover and boiled for ten minutes in one per cent. soda solution. There is practically always time enough for this procedure. If hot water is used, five minutes are required to bring it to the boiling-point; if the water be cold, fifteen to twenty minutes are necessary. After ten minutes' boiling the tray containing the instruments is lifted out of the water and the instruments upset into a basin of carbolic or lysol solution. Of course the instruments should not be handled.

For the sterilization of dressing material a second tray, half the height of the larger gauze tray, into which it fits, is added, the dressing material is placed on top of this tray, and is sterilized in the steam of the boiling water.

The whole apparatus seems to me as simple as possible. I carry along in each case what of instruments I think will be necessary. If I know nothing of the case in advance I take along everything; if I have examined a primipara a week before her confinement and have found the fœtal head well engaged in a normal pelvis, I know that I shall not require any instruments for craniotomy, etc.

It goes without saying that the apparatus is equally available for gynecological instruments.

The apparatus is made by Messrs. George Tiemann & Co., of this city, and costs, complete, $18 net. It is compact, neat, of moderate weight, and fills all indications demanded in modern obstetrical practice.

Leprosy	0	0

Migration of Syphilis from East Asia into America by Way of the Behring Sea.—Syphilis is admitted by Professor Brinton to have existed in America when Columbus landed. Yet this author will not see any connection between ancient Americans and East Asiatics: in fact, he denies it positively. He is inclined to think that the disease existed independently in America and in Europe, and that Columbus, therefore, could not have introduced it from Europe to America. Now, if syphilis existed in America, that is, the now Spanish America, before the arrival of Columbus, it either originated in the South, in moisture and heat, to speak with the Chinese, for nowhere but in the South have we any evidence of its presence, or it was brought over, say from China or Japan. This happened, if at all, by way of migration, for commerce there was none. We hear, indeed, of a drifting of Chinese junks to ancient Peru and Ecuador; of course this may be only a myth. But the fact that the Aztecs of Mexico, and the Incas of Peru, the most ancient American races, came from the North is not mythical. If they came from the North, say from the Behring Sea, it is reasonable to believe that they crossed from the nearest point of Eastern Asia.—Ashmead, in *Journal of the American Medical Association*, February 5, 1894.

Amendment of Medical Statutes.—The following amendments to existing laws relative to the State medical examinations have been introduced at Albany and are now in the hands of the Senate Committee on Public Health.

Appropriation and Expenses.—There shall be appropriated annually, to be paid to the regents by the treasurer on the warrant of the comptroller, such sums of money as shall be necessary for the conduct of the examinations provided for by this article. Out of the moneys so appropriated, or out of any moneys in their hands, the regents are authorized and directed to use as much thereof as shall not exceed in the aggregate the sum of $25 for each and every candidate who shall be admitted to examination according to the provisions of this article. And out of the moneys which the regents are hereby so authorized and directed to use, they shall pay all proper expenses incurred by the provisions of this article, except compensation to medical examiners; and any surplus at the end of each fiscal year shall be apportioned among the three boards *pro rata* according to the number of candidates whose answer papers have been marked by each.

Admission to Examination.—The regents shall admit to examination any candidate who submits satisfactory evidences, verified by oath, if required, that he: 1. Is more than twenty one years of age; 2, is of good moral character; 3, has the general education required in all cases after August 1, 1895, preliminary to receiving the degree of bachelor or doctor of medicine, in this State: 4, has studied medicine not less than three full years, including three satisfactory courses, in three different academic years, in a medical school registered as maintaining at the time a satisfactory standard; 5, has either received the degree of bachelor or doctor of medicine from some registered medical school, or a diploma or license conferring full right to practise medicine in some foreign country. The degree of bachelor or doctor of medicine shall not be conferred in this State before the candidate has filed, with the institution conferring it, the certificate of the regents that three years before the date of degree, or before or during his first year of medical study in this State, he had either graduated from a registered college or satisfactorily completed not less than a three years' academic course in a registered academy or high school: or had a preliminary education considered and accepted by the regents as fully equivalent; or had passed regents' examinations in arithmetic, elementary English, geography, spelling, United States history, English composition, and physics. Students who had matriculated in a New York medical school before June 5, 1890, shall be exempt from this preliminary education requirement, provided the degree be conferred before August 1, 1895. The regents may, in their discretion, accept as the equivalent for any part of the third and fourth requirement, evidence of five or more years' reputable practice of medicine, provided that such substitution be specified in the license. This act shall take effect upon October 1, 1894.

The Historian Parkman and His Physicians.—Francis Parkman, now in the first glory of his posthumous fame, in a brief autobiography, in the possession of the Massachusetts Historical Society, with a good-natured irony thus hits off his various physicians: "The Faculty of Medicine were not idle," he says, "displaying that exuberance of resource for which that remarkable profession is justly famed. The wisest, indeed, did nothing; commending his patient to time and fate; but the activity of his brethren made full amends for this masterly inaction. One was for tonics, another for a diet of milk; one counselled galvanism, another hydropathy; one scarred him behind the neck with nitric acid, another drew red hot irons along his spine with a view of enlivening that organ. Opinion was divergent as practice. One assured him of recovery in six years; another thought that he would never recover. Another, with grave circumlocution, lest the patient should take fright, informed him that he was the victim of an organic disease of the brain which must needs despatch him to another world within a twelvemonth; and he stood amazed at the smile of an auditor who neither cared for the announcement nor believed it. Another, an eminent physiologist of Paris, after an acquaintance of three months, told him one day that from the nature of the disorder, he had at first supposed that it must, in accordance with precedent, be attended by insanity, and that he had ever since been studying him to discover in what form the supposed aberration declared itself, adding, with a somewhat humorous look, that his researches had not been rewarded with the smallest success."

Pathogeny of Pneumonia.—Dr. Wassermann, assistant in the Institute for Infectious Diseases under the direction of Professor Koch, writes on the differential diagnosis of inflammatory lung affections. Pneumonia may be caused in several ways, hence the importance of a careful microscopical examination of the sputum in each case. We are acquainted, he points out, with a number of parasites capable of exciting pneumonic disturbance—Fraenkel's diplococcus, Pfeiffer's influenza bacillus, Friedländer's bacillus, streptococci, and staphylococci. In two cases of lung disease of long duration, with a temperature of the septic type, the sputum was found to contain large numbers of streptococci, but no tubercle bacilli; had it not been for the examination of the sputum the cases could easily have been taken for tuberculous disease. Dr. Wassermann controverts the commonly held opinion that the prevalence of pneumonia

during epidemics of influenza is due to the effect of the attack of influenza, rendering a person more susceptible to pneumonia. In the Institute for Infectious Diseases, in cases of pneumonia with influenza, the sputum was found to contain pure cultures of influenza bacillus, and hence this pneumonia is to be regarded as being an extension of the influenza process.

The Discovery of Chloroform.—The *Century Magazine* for January contains a paper on "Sir James Simpson's Introduction of Chloroform," written by his daughter Following up the American discovery of sulphuric ether as an anæsthetic, we are told of Simpson's infinite pains and frequent disappointments in his search for a more effectual means of avoiding the agonies of operation. Sir James was daring even to rashness in his experiments, and, as a rule, tried the effect of agents upon himself, more than once endangering his life in doing so. The account of the first trial of chloroform reminds one somewhat of the Bacchanalian orgies of Squire Western and his bucolic companions; and, despite the weighty interests with which the sitting was fraught, we cannot repress a smile at the ludicrous disappearance of the investigators "under the table." On returning home after a weary day's labor, Dr. Simpson, with his two friends and assistants (Drs. George Keith and Mathews Duncan), sat down to their somewhat hazardous work in Dr. Simpson's dining-room. Having inhaled several substances, but without much effect, it occurred to Dr. Simpson to try a ponderous material which, on account of its great weight, he had hitherto regarded as of no use. It happened to be a small bottle of chloroform. It was searched for, and recovered from beneath a heap of loose paper; and, with each tumbler newly charged, the inhalers resumed their occupation. Immediately an unwonted hilarity seized the party; they became bright-eyed, very happy, and very loquacious, expatiating on the delicious aroma of the new fluid. The conversation was of unusual intelligence, and quite charmed the listeners—some ladies of the family and a naval officer, a brother-in-law of Dr. Simpson. But, suddenly, there was a talk of sounds being heard like those of a cotton-mill, louder and louder; a moment more, then all was quiet; then a crash. On awaking, Dr. Simpson's first perception was mental. "This is far stronger and better than ether," said he to himself. His second was to note that he was prostrate on the floor, and that among the friends about him there was both confusion and alarm. Hearing a noise, he turned about, saw Dr. Duncan beneath a chair; his jaw had dropped, his eyes were staring, his head was bent half under him; he was quite unconscious, and was snoring in a most determined and alarming manner. More noise still, and much motion. And then his eyes overtook Dr. Keith's feet and legs making valorous efforts to overturn the supper-table, or more probably to annihilate everything that was on it. After such convincing testimony to its power, Sir James lost no time in publicly proclaiming the virtues of the new anæsthetic.

Sanitary Insurance.—Dr. G. W. Steeves proposes, in the *Nineteenth Century*, a method of sanitary insurance which has the merit of novelty and which seems not impracticable. This plan is that any city or district may organize for itself a sanitary protective and insurance association founded for the purpose of providing the public with a source of protection against unsanitary dwellings and surroundings. The definite objects would be: 1. To examine into the sanitary condition of any building previous to tenancy, or after, and to afford skilled advice on hygienic matters or appliances, either on existing premises or on the plans of proposed arrangements of new buildings. 2. To issue certificates respecting the sanitary condition of dwelling-houses and buildings. 3. To provide the means by which a cleanly and wholesome state of dwelling-houses and premises may be maintained. 4. The sanitary registration of dwellings. 5. The insurance of buildings against a defective sanitary condition.

Succi's Digestion.—Dr. Sansoni has published, in the *Riforma Medica*, some notes on the gastric secretion of Succi, the fasting man, which are pathologically interesting. It would appear that Succi's stomach does not secrete hydrochloric acid, the defect being functional and not the result of an anatomical lesion. It is believed that prolonged fasts have brought about this state of things, and that in consequence of it the sensation of hunger is suppressed. The absence of the acid, moreover, probably helps in the resistance to the effects of starvation. The question arises whether we would not all be better without hydrochloric acid in our stomachs. There would be then no fear of over-eating and the disastrous effects of gluttony would forever be removed. One formal meal a day, containing of proteids 118 grammes, carbohydrates 500, and fats 60, with a pinch of salt, would carry us all through.

The Staining of Living Cells.—Professor Ehrich, at a meeting of the Berlin Medical Society, said that for a number of years he had been attempting to decide certain biological therapeutic medicinal questions by the introduction of coloring material into the bodies of animals. In the course of his investigation he propounded the question, which of all coloring material had the greatest affinity to the living animal. The answer was very simple. On experiments with tadpoles he found that neutral red was the best suited for staining purposes, a material that had not hitherto been used in microscopic work, but which could be obtained from Grubler. If the color was diluted and an alkali added, a fuchsin color was produced. From the manner of staining it could be seen whether an animal tissue was alkaline, weakly alkaline, or acid. If, for instance, a tadpole was made to swim in a weak solution of neutral red (1 to 2,300,000), it was astonishing how it absorbed the coloring material. It became red in a quarter of an hour. If they were kept in the fluid a longer time, all the tissue of the body, the brain, etc., became perfectly red. The speaker knew of no material so suited for staining living cells as neutral red. Such coloring material must, therefore, be possessed of two properties: 1. It must be able to penetrate the covering membranes of the living tissues. 2. There must be something in the cells that has an active attraction for the staining material.

Professor Von Esmarch has done 20,000 important operations.

FURTHER OBSERVATIONS ON CHRONIC RELAPSING APPENDICITIS—EIGHTEEN CASES, WITH ONE DEATH—LIST OF FOUR HUNDRED AND FIFTY OPERATIONS.

BY WILLIAM T. BULL, M.D.,

NEW YORK.

PROFESSOR OF SURGERY, COLUMBIA COLLEGE; SURGEON TO THE NEW YORK HOSPITAL.

ABOUT a year ago I reported to the Practitioners' Society twelve cases of chronic relapsing appendicitis which had been subjected to operation, with one fatal result.[1] My purpose now is to record six additional cases, all successful, and to present fuller statistics bearing on the mortality. All these operations have been done because of acute attacks so frequently repeated as to lead to the belief that there was a chronic appendicitis which had no tendency to disappear spontaneously or with the aid of medical measures. These attacks seriously interfered with the occupations of the patients. In most of the cases there was palpable evidence of chronic inflammation in the shape of a tumor in the iliac fossa, and a history of chronic invalidism to a greater or less degree, marked by such symptoms as irregular pain or discomfort in the iliac fossa increased on exertion, irregularity in action of the bowels, flatulence and pain, and distention after eating. In about the same number of patients—eighteen or twenty—I have advised against operation because the attacks were at long or irregular intervals and few in number, and the condition in the interval was apparently one of good health without tumor and without history of intestinal irregularity or pain. These cases may be called recurring appendicitis in distinction from the others. It is fair to state that one or two operated cases are "on the line" between these two divisions.

For the histories which are appended I will substitute a brief summary of the symptoms, clinical features, and condition of the appendix at operation, drawn from a consideration of the entire eighteen cases. It is worth recording that but 2 of 18 patients were females, fifty and fifty-five years of age respectively. Of the ages of the others, there were 4 between fifteen and twenty, 7 between twenty and thirty, 4 between thirty and forty, and 1 between forty and fifty. Nine patients have presented histories of severe attacks lasting two weeks or more, with vomiting at the outset, and, later, fever, prostration, abdominal pain, and distention. Several of these have not been entirely well and strong after the first attack, and the inflammatory exudation or tumor has resolved very slowly. In 7 pus was found at the operation, either in the appendix or close by in the false membrane, and the adhesions were firm and thick in the majority. By these adhesions the appendix was firmly held in various positions. It was in four instances so closely united to the small intestine as to make it probable that its contents had previously found escape in that way. One small purulent focus contained a fecal concretion, and in 2 cases the cæcal end of the appendix was obliterated. All of these patients had a distinct tumor in the iliac fossa deeply or superficially situated according as the adhesions had drawn the appendix to the anterior parieties or into the iliac fossa. The volume of the tumor was influenced by the inflammatory thickening and involvement of the omentum. It is to be noted of these cases that the history extends over a brief period: in 5, under one year; in 2, under eighteen months; in 2 it covers two and a half and four years, respectively.

Six patients gave histories of frequently repeated (three to ten per year) attacks of moderate severity, lasting a week or less, with little or no fever and no marked prostration. Two of these had constant discomfort in the iliac fossa and pain on exertion. In these the adhesions were lighter, the appendix not so buried in dense membrane, its lumen patulous but bent, stenosed, or contracted at one point and dilated at another. In 2 patients the lumen was entirely obliterated and the appendix adherent in the iliac fossa. On examination 4 presented a distinct tumor, 1 none at all; in the sixth the tumor had been felt only at the time of the attack. These milder and more frequently recurring cases have a longer duration, in five of the six extending over three years.

One patient had been drained only, for an abscess eighteen months previous to operation. The appendix was not found. Following recovery there were occasional attacks, confining him to the bed for a day or two with local pain, tenderness, tympanites, and constipation. Here no tumor could be made out. At operation the appendix, with lumen still patent and sharply curved, was buried in a thick layer of false membrane on the surface of the cæcum.

One patient gave a history of four characteristic attacks, of five to seven days' duration, during two and a half years, with steady discomfort in the iliac region for six months before operation. A tumor was felt, under ether, by the physician a month before my examination, when none was detected. The operation revealed no trace of the previous inflammation beyond an adhesion of the omentum to the anterior abdominal wall and what the pathologist called a normal appendix, though there was thickening of the mucous coat. The patient, a woman of fifty years of age, has experienced entire relief of symptoms.

In one patient (Case XIII.) the operation was undertaken with the view that a neoplasm, chronic appendicitis, or colitis might cause the symptoms. An appendix was found slightly curled up by adhesions and contracted at its middle. A small uterine fibroid and several hemorrhoids were ligated. No distinct tumor was felt before operation; but all symptoms were relieved, and the patient has been well now for a year and ten months.[1]

That the diagnosis is not always clear, I have learned from several experiences quite independently of this list. I have mistaken cancer of the ileo-cæcal region in two instances for chronic appendicitis, and been unable to decide without exploration in a third case. When there are such symptoms as diarrhœa with bloody and mucous stools, and occasional attacks of obstruction with a persisting tumor and gradual emaciation, one cannot doubt the existence of cancer. But this group of signs does not exist in the early stages, at the only time when there is a chance for cure by excision of the neoplasm. Persistent pain and persistent definite tumor point to cancer; less severe and occasional pain and a less distinct tumor which disappears at times argue in favor of appendicitis. But these are only indications of what may be the probable

[1] MEDICAL RECORD, March 18, 1893.

[1] This case was mentioned in my previous paper as an exploratory incision in which the normal appendix was removed. It was incorrect, as I have learned by finding fuller notes than were at my disposal earlier.

condition, and exploratory incision must be our reliance for diagnosis. In one instance of peritoneal tuberculosis, I supposed I was dealing with chronic appendicitis, and the condition was made clear only after ether was administered. Dr. Kinnicutt, also, saw this patient. A clerk, aged twenty, had typhoid fever three and hæmoptysis four years previously to admission to hospital. In last two months persistent dull pain in central region of abdomen, with sharper colicky pains, almost daily, of several hours' duration, referred to right side of abdomen. In last two weeks a tenderspot in iliac fossa, which on examination is found to correspond with a mass the size of an English walnut about midway between spine of ilium and navel. This is superficial. Other organs healthy. No fever. Pain interferes with occupation. Laparotomy, May 28, 1891. After narcosis was complete the tumor could be distinctly felt, and a second smaller one near it. This and the antecedent history of hæmoptysis, and the fact of the pain being more widely diffused than is usual in appendicitis, suggested at once the diagnosis of tubercular peritonitis. The cæcum was covered on its outer and posterior surfaces by a firm mass of inflammatory membrane in which the appendix was embedded. It was not removed. The mesentery contained numerous enlarged glands, two of which constituted the tumors felt on palpation. One of these was examined; its centre was cheesy and it was pronounced tuberculous by Dr. Ferguson. Recovery was prompt and followed by three months' rest in the Catskills. Two years later the patient was reported (not seen) as being in apparent good health.

In another instance a young female domestic was referred to me with the statement that an operation had been advised for relapsing appendicitis. She had frequent attacks of nausea and pain referred to the umbilicus and epigastrium. There was no tumor of the iliac fossa, but this region on both sides was tender at one point on deep pressure. I found the right ovary tender, suggested douches and external counter irritation. The symptoms were relieved for six months, but soon afterward steady epigastric pain and vomiting and distress after eating made it clear that she was suffering from ulcer of the stomach. Here undue stress had been placed on the existence of a tender point in the right iliac fossa. This symptom or sign alone is of little value, in my opinion, unless interpreted by the aid of a history of characteristic attacks, in some of which a larger area of tenderness has been detected by a competent observer and also after comparison with the left side. In one case the tenderness was felt only posteriorly in the lumbar region.

It is desirable to remove the appendix in case the symptoms are reasonably definite, as is shown by the testimony of one case in which the operation had to be repeated and another in which after recovery there was a return of the symptoms. The first case is No. 1 of the first series,[1] the second was published by Dr. Coley in 1891[2] as a case of chronic peritonitis. W. E——, aged twenty three, single, German, was admitted to the hospital on September 5, 1889, and was treated on the medical side for typhoid fever. He was discharged cured on October 28th. After leaving the hospital, he had recurrent attacks of abdominal pain, mostly in the right iliac region, and extending into the lumbar region. He was readmitted on January 1, 1890, and transferred to the surgical side on March 15th. During this time he had had two or three attacks of pain in the right iliac region, accompanied by an indistinct tumefaction and tenderness on pressure. Rectal examination was negative. His general condition was fair; there was moderate constipation, with some nausea and occasional vomiting. At the operation, March 15, 1890, the cæcum seemed to be abnormally fixed in the pelvis, and the appendix could not be found. Extensive manipulation was not thought desirable, and the wound was closed. No drainage was used. The wound healed quickly, and the patient made a good recovery. In the third week after the operation he had persistent nausea and vomiting, but no abdominal pain; a slight feeling of discomfort only. He was up and about in the third week, his condition improved somewhat, and he was discharged. Fifteen months later he reported to me that he was usually well, worked hard as a baker, but had been obliged to stop work four times for several days on account of obstinate abdominal pain without any reference to constipation.

The mortality following the operation has been variously estimated of late. In my previous paper I could find, including my own, but seventy-six cases recorded, and my fatal result was the only one. Since then, by personal correspondence and a renewed search of the journals, in which Dr. Powers has given his kind co operation, I have brought to light a much larger number of cases. Many of my colleagues here and in other cities have given us great assistance, as will be seen by the appended table. Four hundred and fifty operations[1] have been performed, with eight deaths, which would give a mortality percentage of $1\frac{7}{7}\frac{7}{0}$ per cent. This would be raised to over two per cent. if I could include four other fatal cases of which I have indirectly been informed. If we look at the record of individual surgeons and strike an average, we should say that five or six per cent. would be a fairer estimate. Over eighty per cent. of operations have been performed in this country, and three hundred and forty-one cases have been communicated to me by the operators themselves. These figures convey another impression to my mind, which is that we have a large amount of material stored up in private and hospital note-books which could with great advantage be subjected to study and analysis. The absence of such studies by men whose experience has been ample, leads me to think that they are yet in doubt as to many points in the natural history, diagnosis, and treatment, while the success of operative methods leads to their frequent adoption. We need more carefully recorded cases not only of the patients who come to operation, but those who have successive attacks relieved by medical measures. There are many gaps to be filled between the position of the surgeon who operates only when there are definite symptoms of chronic disease which have been found by operation to correspond with definite lesions of the appendix, and those who resort to operation after one or two attacks in individuals who have no symptoms, because they believe future attacks must occur in the order of nature and must endanger life. The position of the former may be too conservative, but I think it is "up to date" with the knowledge we have at present. The attitude of the latter is unscientific, as their statements are not borne out by demonstration. When it is well established by numerous observations that we must "consider an appendix once so affected as to deserve the name of appendicitis" (to quote from a recent paper), "whether from tuberculosis or trauma, as a permanently diseased structure," or that it is "a risk to life to leave an infected appendix baited and set in the iliac fossa," I shall be ready to advise and perform removal of this useless appendage so soon as a patient has recovered from one attack, light or severe.

The number of these collected cases suggests that there is a tendency to recur in a greater percentage than has been hitherto stated. Fitz's first estimate of eleven per cent. must be too small. This point can only be determined by full reports of all classes of cases. If the natural tendency of the majority is to recur, if, as above quoted, the appendix once inflamed is a permanently diseased and threatening condition, we have an argument in favor of operating for far less urgent symptoms in the acute attack. Physicians must co operate with surgeons in determining this point; and I can conceive no better way than for the Congress of American Physicians

[1] MEDICAL RECORD, March 18, 1893.
[2] A Clinical Report of Operative Surgery. New York Medical Journal, April to August 1891.

[1] Braine (Archiv. de la Policlin. de Paris, 1892, p. 313) reports Quénu as having performed forty-two operations, all successful. I have not included these because it is not definitely stated that all the operations were done in the period of quiescence.

and Surgeons at its coming meeting to appoint a committee to collect and edit reports that may be contributed on all questions relating to this important subject.

These observations are intended merely as a guide-post on the way of progress toward a fuller knowledge of this disease. I therefore forbear from formulating any conclusions beyond such as can be inferred from the record of the cases.

* Communicated by Dr. Miles F. Porter, Fort Wayne, Ind.

Case XIII.[1]—A single woman, aged fifty-five, patient of Dr. D. M. Stimson, had had several attacks of pain with tenderness in the ileo-cæcal region during four months She had frequently diarrhœa with mucus and blood in the stools, could not digest solid food, and often complained (aside from the attacks already mentioned) of dull pain in the right side of the abdomen. Examination was negative, except for an indistinct tender fulness in the right iliac fossa and several internal hemorrhoids. Abdominal wall thick.

April 22, 1892.—Operation: The appendix presented itself at once on opening the cavity, with a thin slip of the omentum attaching it in a curled-up form lightly to the cæcum. It was four inches in length; its extremity for one inch and a half stiff and hard; the rest soft. Its lumen, which was patent, contained two small fecal masses and was lightly constricted at the middle. It was excised, a small pediculated fibroid of the uterus (size of an apple), and three hemorrhoidal tumors tied off. Recovery uneventful, save for a small mural abscess. Since then she has been perfectly free from pain or functional disturbance of the intestines. Dr. Ferguson reported the appendix wall in its distal half to be the seat of chronic inflammation.

Fig. 1.

Case XIV.—A student, aged nineteen, a large eater and frequently constipated, was sick with abdominal pain and vomiting for two days on a yacht. On reaching Seabright, June 24, 1892, Dr. R. B. Kimball found no tumor, but tenderness and resistance in the iliac fossa; fever, 103.5° F. Temperature fell in two days; vomiting ceased, but pain and induration continued. Two weeks later I examined him with Dr. Kimball, and found a firm inflammatory mass between the iliac fossa and rectum, as large as the fist. It was not tender, there was no fever, and but slight pain. The bowels moved regularly. A week later the mass was one-half smaller, without tenderness, and no temperature above 99⅕° F. The patient was allowed to get up, to take moderate exercise, and use pills of aloes, belladonna, and strychnia. In the following November and January he was apparently quite well, and I could find no trace of the tumor. The second attack began March 15, 1893, at 2 A.M., several hours after bolting a hearty meal, with abdominal pain and vomiting. Dr. Schiff, of New Haven, at 5 A.M. found him in a condition of mild collapse, with severe pain and still vomiting.

Fig. 2.—Mass of Thickened and Rolled-up Omentum Containing the Appendix.

March 16th, 8 A.M.—The vomiting was repeated. Temperature normal; pulse, 88. At 1.30 P.M.: Pulse, 100; temperature, 101° F.; right side of abdomen rigid; slightly tender in centre of iliac fossa, and resonance in

[1] The twelve previously reported cases are to be found in Medical Record, March 18, 1893.

creased on percussion. Gas passed. I saw him at this time and advised removal to New York. There was a spontaneous movement in the evening, with pulse, 80; temperature, 100° F.; rectum, 101° F. In the following three days the abdomen became natural and free from tenderness, and there was recognized a distinct induration outside the right rectus muscle and above the middle of Poupart's ligament.

After consultation with Dr. J. W. McLane and Dr. McBurney, operation performed March 20th. The omentum covering anterior wall of cæcum was discovered at once on incising the peritoneum. It was firmly adherent to the anterior parietes opposite the lower third of Poupart's ligament, and formed a pretty firm mass as large as a hen's egg, being rolled upon itself and enclosing the appendix and a layer of old granulation-tissue. (Figs. 2 and 3.) The appendix was curled upon itself, its cæcal end obliterated; its lumen contained a few drops of thin pus. It was removed after ligating the omentum, where it was spread over the cæcum. In doing this firm adhesions to small intestines were torn through carefully, but the serous coat was stripped off in two places, an inch and a half, and a half inch in length, which necessitated the use of Lembert sutures. The catgut ligature slipped off the soft and friable omental stump, and half an hour was spent in drawing it, with the transverse colon, down, and securing the vessels. The cavity was irrigated with boiled water, and a tent of iodoform gauze left in. For two days there was frequent vomiting with slight fever (100°–101° F.) but no pain or tympanites, then recovery ensued. The gauze was withdrawn on the third day, the wound was healed at the end of two weeks, and the patient was out of bed at the end of three weeks.

Fig. 3.—Omentum Unrolled Showing Portion of Appendix in Old Abscess Cavity.

Case XV.—A merchant, aged twenty-eight, patient of Dr. Henry C. Pest, of Fultonville, N. Y., presented the following history: He was always well up to the first attack, in October, 1891, when he suffered for twenty-four hours with sharp abdominal pain and collapse. The second attack (January, 1892) was marked by pain and vomiting at the outset. It followed the ingestion of green apples, and lasted six or seven weeks, with fever, right-sided abdominal pain, tenderness and induration, and general abdominal swelling. The third attack, of three weeks' duration, in October, 1892, was of less severe character. A fourth attack (January, 1893) began (after two days' discomfort in New York) with chill, followed by fever and the usual local symptoms, was attended with great prostration, and lasted three weeks. A week later (February 15, 1893) there was a fifth attack, marked by return of the abdominal pain without vomiting, which confined him to the house for two weeks. He had lost flesh, and looked anæmic and felt weak. On examination by Dr. Kinnicutt and myself, the abdominal wall was found thin and relaxed. Beneath the outer edge of the right rectus a soft tumor (size of one-half the index-finger), not adherent, movable antero-posteriorly. At the operation, March 16, 1893, St. Luke's Hospital, this tumor was found to be made up of the appendix sharply bent on itself and enclosed in a layer of false membrane, closely uniting the cæcum on its internal and inferior aspect to a loop of small intestine. The appendix was two and one-half inches long, and its lumen was obliterated at the bend and at the cæcal end—forming two small cavities with only mucous contents. Iodoform gauze was employed for three days. Wound healed in three weeks.

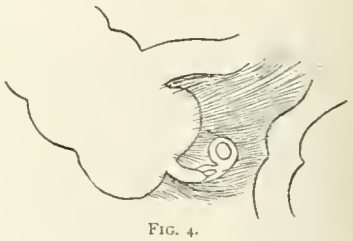

Fig. 4.

Case XVI.—A clerk, aged twenty two, patient of Dr. Van Cott, of Brooklyn, had three years ago an attack of pain in abdomen and right iliac fossa, with fever and vomiting; he was ill for one month. Since then has had every second or fourth month a similar attack, of less severe character and lasting about a week. When seen by me with Dr. Van Cott, October, 1893, he had been sick three days with characteristic symptoms, which were abating. In the iliac fossa there was a slightly tender, deep seated, indurated area, which had disappeared by the eighth day, while the temperature had become normal and the bowels had moved naturally. The operation was then done. The omentum was found adherent to the anterior parietes covering the cæcum, and the appendix, which was short, club-shaped, and thickened, was held by slight adhesions between the cæcum and a loop of ileum. The mucous membrane was thickened and folded into numerous ridges, the lumen patulous, and nowhere stenosed. Dr. Van Cott reported it to be the seat of chronic interstitial inflammation in the serous and muscular coats. Primary union resulted, and the patient was up on the seventeenth day.

Fig. 5.

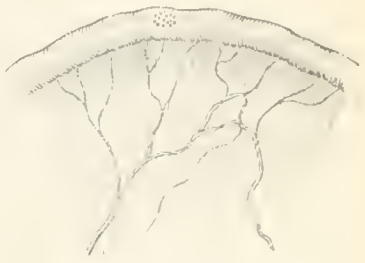
Case XVII.—A laborer, aged twenty, presented himself at the New York Hospital Out-patient Department, October 8, 1893, with the story that four months previously, he had been sick abed for three weeks with "inflammation of the bowels," the pain being on the right side low down. A few days later he was taken again with similar symptoms, and was in bed four weeks. He felt well till a month ago, when the pain returned and compelled him to give up work. On examination by Dr. Nammack and Dr. Forbes, there was felt in the right iliac fossa, beginning opposite the middle of Poupart's ligament and extending upward and outward, an elongated tender tumor, three and one-half inches long by one

inch in breadth. It was attached to the abdominal wall. There was no fever. Slight dulness. He was admitted at once to the hospital, and operated on four days later, October 12, 1893. The swelling remained unchanged. An incision on the outer side of the swelling disclosed the cæcum adherent, and the appendix curled upward and forward around its lower end. At its middle the appendix was closely united to the small intestine, and its tip was detached from a mass of inflammatory exudation which infiltrated the abdominal wall and gave rise to the tumor which was felt. In the centre of this exudation, near the tip of the appendix, was a layer of softened granulation-tissue with a few drops of pus. After excising the appendix the upper half of the wound was sutured; the lower part packed with gauze. Healing was complete without complications in five weeks.

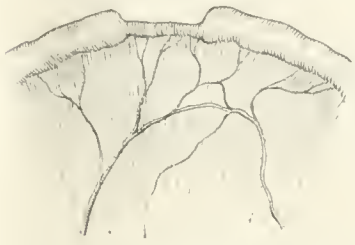
FIG. 6.

CASE XVIII.—A merchant, aged twenty-seven; patient of Dr. J. L. C. Whitcomb; consulted me on October 9, 1893, for frequent attacks of abdominal pain, which he had experienced during the past three years. The first attack was attended with chills, prostration, fever, and abdominal pain; the second occurred nine months later, but without any chill. Since then, two years and three months, he has had an attack about every month, lasting two days. The pain is felt below and to the right of the navel; the abdomen is tender there; there is flatulence, which is relieved by rest and laxatives. After meals there is often tenderness in the right iliac fossa, and the weight and pressure of the clothing is uncomfortable. On examination a small, slightly tender area, of the size of half the thumb, was found midway between the navel and the iliac spine on the right side. At the operation, which was done November 3, 1893, a strip of omentum was found adherent to the cæcum. The appendix was bound by false membrane around the convex end of the cæcum, with its tip lightly adherent to the peritoneum of the iliac fossa. It was three and one-half inches in length; in its proximal three-fourths it was dwindled to a cord no more than one-fourth inch in diameter, while its tip was a trifle larger. No lumen could be discovered with a fine probe. Dr. Ferguson reported that the mucous membrane had entirely disappeared. Primary union, and discharge from hospital on the twenty-first day. A small stitch abscess occurred subsequently.

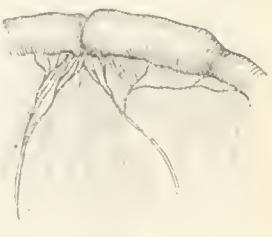
FIG. 7



Ecclesiastical Honors to Hydrotherapy. — Father Kneipp, of Morishöfen, the author of a system of hydrotherapy, was recently called to Rome by the Pope, who desired to create him a Monseigneur, and also, it is said, to consult him professionally. Upon the occasion of his visit, a few weeks ago, he improved the opportunity to deliver a lecture upon the virtues of his peculiar hobby. The lecture was delivered in excellent Italian in the drawing-room of the Hôtel de Minerva, before a large audience of clericals and lay-folk, both Romans and foreigners. His discourse was chiefly upon the value of cold baths and a simple diet as a preservation of health. The Monseigneur is a man of splendid physique, and bears witness in himself to the virtues of cleanly living as a means of warding off the minor ills to which humanity is exposed.



THE PRODUCTION OF ILEAL INTUSSUSCEPTION WITH CARBONATE OF SODIUM.[1]



BY ROBERT T. MORRIS, M.D.,

NEW YORK.

IN order to save time and avoid unnecessary handling of bowel in abdominal work, it is frequently a matter of considerable importance for the surgeon to determine quickly the direction in which the intestine runs. The method which is perhaps most commonly employed consists in exciting reversed peristalsis of the bowel by applying certain irritants, and a note has recently been going the rounds of the medical press to the effect that carbonate of sodium is the best material for this purpose. I have demonstrated by experiments upon rabbits that carbonate of sodium is dangerous, because of its influence in producing intussusception of the small intestine. The mechanism of the process consists in a tonic spasm of the circular muscular fibres of the bowel at a point that has been touched with the sodium salt, and for a considerable distance cephalad and caudad from that point; the segment of intestine which is in a condition of spasm being then slowly, but progressively, intussuscepted by the action of the longitudinal muscular fibres of the unaffected bowel. Several inches of the intestine will eventually become intussuscepted in some experiments, the intussusceptum remaining within the intussuscipiens after normal peristalsis has recommenced. This mechanism is the opposite of that which occurs as a post-mortem phenomenon, as I have observed it in one case. In that case the intussusception resulted from a wave of relaxation of the circular muscular fibres of the ileum, allowing a normal segment of bowel to become deeply introverted within the relaxed portion, the mechanism seeming to depend upon the fact that the nerves of the longitudinal muscular fibres remained active longer than those of the circular fibres.

FIG. 1.—Ileum of Rabbit at Moment of Application of a Trifle of Carbonate of Sodium.

FIG. 2.—Ileum, Twenty Seconds Later. Spasm of Circular Muscular Fibres.

FIG. 3.—Ileum, Five Minutes Later. Intussusception Progressing.

The demonstration of the action of carbonate of sodium which I now give upon an anæsthetized rabbit, explains perfectly the action of the salt, rather more than two inches of the ileum becoming intussuscepted at the end of ten minutes as a result of irritating one-fourth of an inch of the bowel. It is thus evident that a patient may have complications due to intussusception after an operation in which carbonate of sodium had been employed for reversing peristalsis, and the surgeon would be unlikely to surmise the nature of the trouble. Chloride of sodium will excite reversed peristalsis, and in a harmless way, so far as I can determine by a satisfactory series of experiments; but it is well to remove the salt as soon as its object has been accomplished.

It seems to me that a certain proportion of cases of "idiopathic" intussusception may perhaps be caused by the absorption of intestinal ptomaïnes which cause spasm of the circular muscular coat of the bowel. This would

[1] Demonstration and remarks at the meeting of the Surgical Section of the New York Academy of Medicine, February 27, 1894.

be more likely to occur in children, because of the sensitiveness of young subjects to influences which are productive of muscular spasm. The intussusception would be of the descending type, unless reversed peristalsis was caused at the same time, in which case ascending intussusception would occur.

SOME LESS CULTIVATED PHASES OF PSYCHOLOGY.

Being Considerations on the Genesis of the Feelings; or the Relation of Desire to the Will-function—Practical Deductions therefrom Concerning the Management of Various Psychopathic Conditions.[1]

By J. LEONARD CORNING, A.M, M.D.,

NEW YORK.

While the literature dealing with the ratiocinative side of mind is exceedingly voluminous, and the subject itself has been deemed worthy of the sages for two thousand years, the feelings and emotions have formed the theme of much less frequent and searching inquiry, the more derivative phenomena of the same, as manifested in the conative (*conari*, to endeavor) or will-faculty, being alone selected for purposes of analysis. Even in this important but relatively restricted field, failure has been the rule, since most of those who have presumed to cultivate it have neglected to trace the volitional faculty to those simple phenomena of which it is the direct issue.

I am sure that every student of psychology who has given the subject thought must have suspected—even though complete logical appreciation was for the time withheld—this glaring inadequacy; and I feel all the more certain, therefore, that the excellent work of clarification so recently performed by Mr. Lester Ward in this important field will meet, at the hands of advanced scholars, that recognition which it so richly deserves.

For reasons which would require much time to elaborate, but of which the justice will at once appeal to this Society, Ward classifies the emotions and feelings—the affective side of mind—as subjective, as contrasted with the relatively objective or thinking faculty. Hence his revival of the two great subdivisions of psychology—first proposed by Kant, but subsequently abandoned by him—the "subjective" and the "objective" psychology. These subdivisions are scientifically explanatory, and therefore convenient; they are worthy, it seems to me, of more general adoption.

It is, however, chiefly with the subjective branch that we shall have to deal in the present argument, wherein the biological precedence which belongs, both chronologically and psychologically, to the affective side of mind will be briefly set forth. It will likewise be expedient to trace the evolution of desire as well as the relation of the same to the conative faculty.

To these propositions may be added a corollary on the scientific cultivation of the will, a problem which, from the standpoint of psychiatry, involves nothing less than the evoking, direction, and strengthening of desire, which in many conditions, and notably in melancholia and hysteria, are prerequisites that will often tax both ingenuity and patience to the utmost.

As has previously been hinted, only recently has an attempt been made to trace biologically the feelings to their primitive elements. The results of these investigations have been startling, since they reveal conclusively that, contrary to popularly accepted belief, the affective faculties immeasurably antedate those of ratiocination, their rudimentary prototype being distinctly traceable even in insect life. Thus, till the close of Jurassic time, vegetation was composed entirely of plants whose reproductive functions were exercised either by the aid of a species of close fertilization, or, when the sexes were separate, by some precarious agency, such as water or wind. Enormous waste in the form of pollen grains was, of course, the inevitable accompaniment of such hap-hazard reproduction.

But there came a change, which is tersely described by Lester Ward, who is not only a sociologist but a botanist, in this wise: "It is known that during the cretaceous epoch the class of plants which now bear true, often showy and fragrant, flowers was introduced. . . . Toward the close of this same epoch, and especially during early Tertiary time, it is also known that insects resembling the present hymenoptera, coleoptera, and lepidoptera made their appearance. So it is now known that the sole purpose of showy and fragrant flowers is to attract insects and secure cross fertilization."

The existence of these flowers, then, is clearly traceable to the agency of insects whose affective functions they, in turn, still further developed. Here, then, in these modest insects is found the embryonic feeling, the sense of the beautiful—the primordial soul-function. But what for us, as students of mental phenomena, is most significant, both from a theoretic and practical standpoint, is the fact that color still remains one of the two most potent means of awakening desire, even where encephalic development has attained its maximum, as in man. The other desire provoking influence is sound, especially, though not exclusively, in the form of concerted minor accords.

Now, when it is borne in mind that the potency of the will, indeed its very existence, is dependent upon desire; and when, in its ultimate analysis, the will-reaction is seen to take place in accordance with the most ardent desire—or at least that which consciously or unconsciously is for the moment most vivid—it becomes evident that the awakening, fostering, and guidance of desire are of the first importance in dealing with a number of important psychical conditions. This is true of many phases of neurasthenia; it is true of hysteria; it is pre-eminently true of melancholia of the simple, non-delusional type. Yet, while the sociological importance of desire in its relation to volition has been well exhibited, the principle, so far as it is applicable in the management of morbid psychic conditions, has been but dimly apprehended.

Exhortations to "use your will;" "interest yourself in this and that;" "take your mind off yourself," and the like, are confessions that while the nature of the psychic difficulty is perceived, its possible removal by external interference is less apparent. But appeals by way of sight and hearing are hardly sufficient—at least not in pathological cases—to evoke or perpetuate desire.

One lady, who was a sufferer from simple melancholy, and whom I sent to the opera, declared that melancholy reflections would frequently obtrude themselves in the midst of the most enchanting harmonies; and that these distressing thoughts afterward interfered with the perfection of what would otherwise have been delightful memories. Conceiving that this lack of complete emotional responsiveness was due, or largely due, to cerebral atony—if I may so express it—I requested her to take a small cup of strong coffee, to which a moderate dose of cognac was added, immediately before going to the opera. As a result of this the triste reflections failed to obtrude themselves, and the resultant memories were without melancholy admixture.

Stimulation of the sensorium before the sensory appeal is made. is the second important element, then, in the awakening of desire. When submitted to final analysis it will be seen that what has previously been propounded constitutes in reality nothing more nor less than a physiological rebuttal of pessimism. I speak of this overthrow, this rebuttal of pessimistic tendencies as physiological to mark the essentially different character of the process as contrasted with the ratiocinative method, which is really that of speculative philosophy. But while what may be termed the physiological rebuttal of pessimism, *i.e.*, its attack by way of the senses, more especially those of sight and hearing, and by increasing, at the

[1] Read at a stated meeting of the New York Neurological Society, January 2, 1894.

same time, the responsiveness of the central nervous system by material means (stimulants, tonics), is the most effective means of awakening desire and arousing dormant volition, it must be confessed that a purely philosophical appeal is exceptionally not without value, especially where we have to deal with persons in whom the intellectual faculties are predominant.

A gentleman of much importance in the literary world, who was under my professional care for a long time, is a good illustration of emotional inaccessibility. He suffered from what he graphically termed "intellectual despair," the keynote of which was the old pessimistic one that "pleasure is a myth, the only real thing in life its pains." This condition of mind was not materially modified in his case by appeals through the special senses and by cerebral stimulation. But when I said to him: "Ah, yes, pleasure is a reality after all; for it has duration, being computable in units of time," he was visibly affected. Yet he was apparently not altogether convinced, for he remarked, "This may be true, but so far as I can judge, the unpleasant sensations far outweigh the pleasant ones. Either I wish for things I cannot get, or I get things I do not wish."

"This," I replied, "is doubtless partly owing to the fact that your desires are not directed in reasonable channels; that you wish for things which, if obtained, would be inexpedient or fraught with injury to others, instead of desiring those which are simple and easily attainable. In part, however, it is owing to the fact that you forget the pleasant sensations you have had, and store away in memory only those which you have not had, but unreasonably crave. Consequently those sombre memories are alone revived and lend a pessimistic coloring to all your reasoning. In future let me urge you to pursue just the opposite course; commit to memory only the euphonic passages, and forget as speedily as may be the dissonances of life. Try, also, to discourage unreasonable desires by substitution, *i.e.*, by exposing yourself to those suggestions which eventuate in simple, easily obtainable wants."

He seemed decidedly affected by this train of reasoning, and subsequently he told me that the resultant transformation in his philosophy was sufficient to antagonize his habitual melancholy to a notable degree.

I have cited this case somewhat in detail, with a view to exhibiting what may occasionally be accomplished by an adroit appeal made to the intellect alone. Such results are, however, exceptional, and alone attainable in persons in whom the emotional faculties are quite subordinate to the intellect.

Indeed, as noted above, the desires—and ultimately the will—are in most neuropathic individuals best evoked and fostered through the special senses, notably sight and hearing; while, at the same time, the receptivity of the sensorium is increased by proper stimulation. Nor is the effect necessarily evanescent; for, by encouraging the subject to recall from memory—several times a day, if necessary—these vivid sensations, a distinct melioristic tendency is gradually imparted to the mind. That due heed should also be given to the general bodily condition; that nutrition must be improved, and gouty or other morbid tendencies antagonized, in order to insure any degree of permanency, is so self evident that the discussion of this aspect of the question would be supererogatory in such an assembly as this.

The expedients here advocated are, then, both physiological and psychological; and so far as is possible in a brief sketch, I have endeavored to set forth the mutuality of their offices in modifying not only the concept but the emotional state, which, from a medical point of view, is on the whole more important.

To have given more than the barest outline of the subtle, not to say labyrinthian aspects of the psychology involved, would have been difficult in a lengthy communication, and is out of the question in a short paper. To do the matter justice would indeed require a volume of no mean proportions.

The question of influencing the mind to the profit of the patient is, however, on all sides, conceded to be a worthy and important problem of neurology. I have, therefore, dared to hope that the inadequacy of this sketch might be atoned for by the value of the discussion which it might possibly evoke.

With the loss of prestige which has apparently overtaken hypnotism; with the consciousness on the part of many neurologists that, in too many instances, the only service rendered by this expedient is to substitute a veritable neurosis for the morbid condition which it was sought to modify, there has arisen, I am sure, a widespread desire for a more intelligent appreciation of what may be done to influence the mind along strictly scientific lines and without melodramatic assistance. It is in this spirit that these observations are made; and what is inadequate in the presentation, may, I trust, gain completeness in the discussion.

53 West Thirty-eighth Street.

A NEW DISEASE OF THE VAGINA—PERIVAGINITIS SIMPLEX.[1]

By J. J. E. MAHER, M.D. McGill,

NEW YORK.

LATE PHYSICIAN TO THE NEW YORK, THE EASTERN AND THE NORTHERN DISPENSARIES, AND THE NEW YORK ASYLUM FOR LYING-IN WOMEN. MEMBER NEW YORK COUNTY MEDICAL SOCIETY, NEW YORK COUNTY MEDICAL ASSOCIATION, ETC.

It is seldom in a lifetime a man is called upon to describe a new disease, and consequently when the phenomena which characterize the malady are not frequently observed, and nothing can be found in the medical literature of many tongues that could in any possible manner be construed into a parallel, it becomes difficult to assert that the description is entirely complete and all that could be desired. No matter how perspicuous the delineation of the salient features of a case may appear, owing to a possible oversight, or a disregard of some minor details as irrelevant, it may require further elaboration to demonstrate the integrity of the whole. The main and important features of this case, however, are so strikingly unique as to present a harmonious and independent individuality. On the strength of this conviction I volunteer the following description of my case:

Mrs. N——, aged twenty three, a brunette, of average height, 106 pounds, of nervous temperament and irritable disposition, was one of those wiry persons who with a delicate physique always enjoy good health. From a causative stand-point her family history presented nothing of importance, unless we consider the fact that the husband was a megalomaniac at liberty, though shortly afterward confined for general paresis.

She had been married one year, and had just been delivered, nineteen days, of her first child, when I was called to see her on account of puerperal hemorrhages and painful sitting. There was nothing unusual about the male child, nor had there been anything unwonted about the pregnancy. Labor at term had lasted only nine hours, when the attending physician, becoming impatient from whatever cause, delivered her under chloroform anæsthesia by means of the forceps. Soon after delivery she began to cough, and two hours later a hemorrhage ensued. This continued nearly three days, more or less checked by drachm doses of fluid extract of ergot every four hours.

About the fourth day a fœtor was observed and met by carbolic douches, on the supposition that it emanated from the genital tract. At the end of two weeks the disagreeable odor had been quite subdued; the lochial discharge remained a bright red, though small in amount; and the attendant, considering the case favorably disposed, left her to get up when she pleased. On his assurance that she was well, she thought she must be so, and accordingly made an effort to rise the following day. When she assumed the erect posture a gush of blood issued from the vagina. Though frightened at the bleed-

[1] Read before the Medical Society of the County of New York.

ing, she determined to sit down, but found she could not, owing to intense pressure pain in the perineum. She repeated this attempt unsuccessfully during the ensuing five days. She had become frantic, almost desperate, and wished to die rather than suffer so.

It was at this juncture that I saw her for the first time. She lay abed, pale and weak, and wore an anxious look of dread, as if wrought up by the existence of a lulled pain easily provoked and aggravated. The pulse was 120; temperature, 100° F. The skin felt somewhat clammy. The tongue was quite clean, yet inappetence and liquid stools obtained. There was no remarkable thirst. The alvine dejections were said to have been of a liquid character every day since the day following delivery, when she had an unprovoked liquid stool similar to the subsequent ones.

I might here interject that she had been constipated for two or three days prior to delivery, and had taken castor-oil, which proved to be emetic instead of cathartic; and also, that owing to the putrescent odor of the constantly escaping flatus, her mother would jocularly say she was rotten. This is significant.

She was restless, and complained of insomnia, painful sitting, and a disagreeable succussion of liquid in the pelvis on moving suddenly in the horizontal position, with a discharge of blood from the vagina on assuming the erect posture.

The entire perineal body possessed a brawny hardness and was lacerated about a centimetre. The laceration presented thickened, everted, indurated lips that could not easily be approximated. The labia in coaptation presented nothing unusual; but when separated, the visual field beyond was astonishing. The vagina formed a rigid tube, all agape, with the cervix and os uteri distinctly visible at its upper end. One would have thought an invisible speculum held the walls asunder. Never did I see the entire and natural calibre of the vagina so remarkably demonstrated. There was a rigid, cylindrical tube, more funnel shaped at its upper extremity, where the cervix protruded into it from above. The mucous membrane was apparently unaltered. Pressure on the perineum and this vaginal tube was repelled as painful, and identified with the painful sitting. The sensation produced was like that of sitting down suddenly on an apple, ball, or some other similar hard substance. This same pain was elicited by pushing the uterus toward the vulva. Very slight pressure in either direction was intolerable. Pressure on either side of the uterus and over its body gave negative results. The body of the uterus was movable without pain, save in the downward direction. A blunt curette was passed into the uterus and it brought away only a few small coagula the size of a pin's head. There was no return of the bleeding after that. Not the slightest fœtor could be detected. The entire genital tract was, as a matter of precaution, washed out with an antiseptic solution. A glycerine tampon was placed in the vagina. The laceration was treated as an ulcer. Three days later the vaginal walls had collapsed at the upper end to the extent of almost hiding the entire cervix from view. Thus far, be it remembered, no speculum had been used. Though the vagina about the cervix seemed soft enough, the latter remained tilted forward. This gave rise to a suspicion of a possible tumor behind the uterus. The constitutional symptoms still persisted, and the condition of the vagina prevented a digital examination. Under the circumstances I made a digital exploration per rectum instead. The tip of the finger, despite the pain from pressure on the perineum, impinged on what seemed a solid, slimy body. Pressure was made on every side of the rectal walls with no avail. The rectum was filled with injected fluid, and the eccentric pressure repeated with the result of bringing the mass within easy reach of the finger. A piece broken off was extracted. In a few minutes the entire fecal tumor was removed. The dislodged, mouse-colored mass produced such a stench as necessitated the immediate opening of every aperture in the room, and the use of a counter-odor of a more agreeable character.

In a few days after the operation all the general symptoms disappeared, all the induration melted away, the vaginal walls collapsed apace from above downward, and the slight laceration of the perineum was all that remained to indicate a pathological condition.

The symptomatology of the above case evidently consists of the general irritative, febrile condition, and the local complex of relative phenomena. For its origin and persistence the former obviously depends on the latter. The general symptoms: pallor, lassitude, anxiety, inappetence, restlessness, insomnia, clammy surface, elevation of temperature, and rapid pulse.

The local symptoms: The feeling of succussion of fluid in the pelvis in the recumbent position; the gush of blood from the vagina on assuming the erect posture; the inability to sit; the sensation of a hard body in the vagina when attempting to sit; the brawny induration of the perineum; the gaping, cylindrical, and rigid condition of the vaginal tube, which rendered the cervix and os uteri distinctly visible at its upper end without the use of artificial aid; the pain of pressure on either end of the tube, upward or downward, identified with that of painful sitting; the limitation of the disease to the immediate environment of the vagina.

To these must be added those symptoms referable to the rectum: The elusive liquid stools, the deceptive freedom of the bowels, the almost constant escape of mephitic gas, and the presence of a decomposing fecal mass.

The etiology of the disease, in this case at least, can only be apprehended and demonstrated on the assumption that the fecal mass existed before delivery, and that the head of the child was forcibly dragged over it.

This stercoraceous accumulation, flattened out by the compressive force of the passing fœtal head, must have expanded the rectal walls to an extent commensurate with the size of the mass. Simultaneously the vaginal walls were distended to their utmost by the fœtal head.

This mechanical extreme distention of either the rectum or the vagina, considered separately, might be easily regarded as within the scope of the functional laws of either organ, and thus be reckoned within physiological bounds; but if it is possible for either organ to be distended beyond the natural limit, the extreme distention of the two organs synchronously surely exceeds the restrictions of physiology, and consequently enters the field of pathology. While the vagina is enormously distended by the head of the child, the recto-vaginal cellular tissue is expanded *pari passu* to an extreme degree—probably its natural limit of physiological resistance. If, when in this condition of extreme tension of the recto-vaginal cellular tissue, the rectum is greatly distended, there is little doubt that the resistance of the intramural connective tissue has been overspent, and that a physiological function forced to excess eventuated in a pathological condition; because the overstrained connective tissue, subjected to the infecting influence of the decomposing fecal mass (which meanwhile remains in close proximity) is overstimulated in the process of repair; and the ensuing proliferative exudation, exceeding the normal limit of restoration, and spreading to the similar contiguous elements surrounding the vagina, induces thickening of its substance to a remarkable degree, and thus establishes the characteristic inflammation which I have termed perivaginitis simplex.

I would therefore consider the causation in this case as depending on the resultant expansion of the intramural cellular tissue, incident to the distentions of the vagina and the rectum conjointly, plus the infection derived from the decomposing rectal mass.

This theory is, to my mind, all the more tenable when it is observed that precedent lends it color and strengthens conviction.

There is a case[1] recorded in French literature in which a child, by forceps' traction, was dragged over a fecal tumor by dint of the muscular efforts of three students in attendance, and in which the patient died a

[1] Flammant: J. de Méd. et de Chir. pratique, t. ii., 1832, p. 332.

month later with abscess of the intramural cellular tissue. Hence mine would not be the first such case in which the attendant dragged the fœtal head over a mass of fecal matter impacted in the rectum.

The diagnosis of simple acute perivaginitis is readily established by the existence of the pathognomonic sign: the patent condition of the vaginal canal. The extent and character of the inflammation can readily be estimated by passing the left index-finger into the rectum, and the right into the vagina. Between the two fingers thus placed the amount of thickening and induration of the recto vaginal cellular tissue can be easily ascertained. Likewise with a curved sound in the bladder the condition of the vesico vaginal wall may be learned. The uniformity of the thickness and consistence is significant in discovering the inception of softening and abscess formation.

It may be suggested as a question of differential diagnosis that œdema of the perivaginal cellular tissue might be mistaken for perivaginitis. Œdema would be a non-inflammatory affection, and consequently would not give rise to general febrile phenomena. Moreover, I have not been able to find a description of such a disease as perivaginal œdema, and, of course, cannot speak more definitely of it than inferential reasoning will permit.

The pathological condition considered by analogy: I have had the good fortune to find the record [1] of a case which occurred in the New York Hospital forty odd years ago, and which will readily be recognized in its pathological aspect as one of inflammation of the peri vaginal cellular tissue.

The patient, a drunkard, was treated for inflammation of the stomach and liver, on account of the violent gastric symptoms. The autopsy showed all the organs of the body outside of the pelvis to be in a healthy condition, save a slight congestion of the lungs. In the pelvis was found her disease, which was described partly thus: "The cellular tissue uniting the vagina to the surrounding parts was very much developed, being about half an inch in thickness, of a grayish ash color, very moist, but retaining a considerable degree of consistence." Owing, however, to the discoloration of parts of the adjoining mucous membranes of the vagina, bladder, and rectum, the case was called gangrene, probably from want of a better and more explicit term. In periostitis, when the blood supply is cut off by inflammation, and the tissue that should be nourished succumbs to necrosis in whole or in part, we might equally as well call it gangrene; but periostitis is more distinctively significant, and consequently, like perivaginitis, preferable.

The prognosis of acute simple perivaginitis, as illustrated in this case, seems decidedly favorable. But when the inflammatory process is excessive or too long overlooked, the cellular tissue may continue to increase in thickness and density to such a degree as to compress and finally obliterate the vaginal arteries supplying the vagina, a part of the rectum, and a part of the bladder; these parts would then undergo necrotic changes. The intumescence of the cellular tissue might soften and dissolve into purulent elements, forming an abscess. Again, these two processes might co operate or succeed, the one the other, in such a manner as to effect the complete segregation of the entire vagina and a part of the cervix from their environment. Such, indeed, was the occurrence in the obscure cases so incompletely described first by Marconet [2] of Moscow.

The treatment of perivaginitis in its simple, suppurative, or gangrenous form, based on general principles, would appear to me very obvious. The source of irritation, first of all, if possible, should be removed. In the simple form thorough cleanliness and a tampon of cotton saturated with boric acid and glycerine fulfil the requirements of the case.

In the more advanced and violent forms the same treatment demanded in periostitis may be here justly and properly applied. Incision to remove tension and permit the escape of suppurative fluid may be imperatively called for. This, with proper antiseptic absorbent compresses, and scrupulous cleanliness, supplies the necessity of the case.

Though in the beginning I did not intend to digress from my own individual case, the temptation to enter upon analogy proved very seductive. Withal I hope the whole will be found as interesting to others as to myself.

ABSCESS OF THE ANTRUM OF HIGHMORE, WITH CASES AND THEIR TREATMENT.

By E. HARRISON GRIFFIN, M.D.,
NEW YORK.
LECTURER ON DISEASES OF THROAT AND NOSE AT BELLEVUE HOSPITAL MEDICAL COLLEGE; ATTENDING SURGEON OF THROAT AND NOSE DEPARTMENT OF BELLEVUE HOSPITAL OUT-DOOR POOR, NEW YORK.

The treatment of this disease in my hands until late years was always unsatisfactory. I began to look upon it as a condition that could be relieved, but hard to cure. Cases were under my care for months; the discharge would diminish under treatment, but in the spring or fall the patient would come to consult me for that discharge from the nose.

I tried every manner of medication; but with always the same result.

Lately I have been following out a different mode of treatment, and I find the disease surrenders under its application and fails to reappear. The diagnosis is simple if the following points are borne in mind:

If the patient should designate one side of the nose as the source of a discharge, suspect an abscess of the antrum, and substantiate it by the following facts: the secretion from the normal nose is a viscid mucus; in an atrophic condition the crust formation takes place; in a hypertrophic state the secretion from the front of the nose is diminished.

In an acute abscess, the discharge is of a creamy consistency, sometimes of a yellowish white, in some cases it may be pure white, at times it may be mixed with blood. The discharge has a very disagreeable, penetrating odor, distinctly different from the odor that is associated with atrophic rhinitis.

To sum up the symptoms of antrum abscess, first, it generally affects only one side of the nose; second, a muco-purulent secretion; third, it will quickly reform after removal.

Pain may be quite a factor in antrum abscess when the ostium maxillary is closed and prevents the discharge from finding its way out through the nose. In these cases the retention of the pus causes a necrosis of some of the bone and it makes its escape through the alveoli, orbit, or cheek. I have seen this occur in two cases where the patient applied to me for the external abscess rather than the primary cause of the trouble.

The older writers on this subject, Merbomius, Drake, Cowper, and Jucker traced the origin of this disease to decayed teeth.

Other authorities, Zuckerkandl, Schiffers, Chatellier, and Krause, describe, as the most frequent cause, the extension of the inflammatory process from the nasal canal.

Bosworth takes the ground that when the nose is obstructed by hypertrophic rhinitis the ostium maxillary is liable to be completely occluded, the normal secretion of the antrum retained, a moderate hyperæmia of mucous membrane resulting in and leading lastly to an abscess. This he points out to be the most general cause of antrum disease. The abscess produced by occlusion of the ostium maxillary rather than an extension of a catarrhal inflammation.

Cases have been reported where the disease has arisen from traumatism; an accident attendant on parturition: division of the infraorbital nerve and facial erysipelas. The disease is purely a local trouble at the start, and this view is entertained by many of the life insurance com-

panies, as two cases that were under my care stated that they had this trouble and were given policies.

We have at our disposal several ways of gaining an opening into the antrum. First, by the removal of the first or second molar tooth. If one of them is carious remove the one that is diseased; if both are apparently healthy, the one that gives pain by the stroke of a steel instrument is the one to be selected. A spray of ether is also a good diagnostic point. After the tooth has been extracted, it is necessary in some cases to drill through a stratum of thin bone, when the antrum is easily reached. This opening should be made as large as possible, as the larger the opening, the better the drainage. If it should tend to close up, the parts can be touched with a twenty-per-cent. solution of cocaine and can be easily enlarged by passing a good steel probe through the opening. Cotton wrapped on the probe will dilate the parts still more.

The opening into the antrum should show a flow of pus. I have had very little trouble with this opening closing up before I desired. Various tubes are in the shops that can be fitted into the opening and attached to an adjoining tooth. Professor Partsch, of Breslau, recommends one with a valve; but it prevents the discharge from coming down through the opening, thus I think his instrument is a drawback.

When the antrum is first opened it is well to probe thoroughly in search of any necrosed bone. Wyeth had a case where a supernumerary tooth produced the discharge.

M. Lawrovier, in 1743, opened into the antrum below the eminence which is felt by carrying the finger as high up as possible under the upper lip, the mouth being closed, namely the malar apophysis. The membrane is dissected off by a transverse incision and the bone is perforated. This operation shows very good results, its fault is that food is liable to enter the sinus.

The antrum can also be reached through the inferior meatus, as proposed by Michuliez.

M. Jourdain, in 1765, treated these cases through the natural opening by injections. This manner of operating is tedious and unsuccessful. The time of a cure varies from a few weeks to two years. Those that were cured in a few weeks must have been very mild cases or the cure incomplete.

Of all the various operations I have stated I prefer the one that requires the removal of a tooth. It is the easiest operation and at the same time the opening is made at the most advantageous point for drainage.

After the opening has been made into the antrum, the case is ready for local medication. A late authority proposes cleaning the cavity and packing it with iodoform gauze. He claims good results with this mode of procedure. It seems rational, as the gauze keeps the parts open and permits a free drainage.

Solutions of zinc, iodine, mercurials, carbolic acid and peroxide of hydrogen have been used as local injections to the sinus. Of all the drugs I have named, and there are any number of others used for this purpose, I prefer the peroxide of hydrogen. I use it from one fifth to one-half strength, in some cases full strength, although I generally use the milder mixture.

The injection of this cavity is painless if the aperture is touched with a twenty-per-cent. solution of cocaine, and time given for it to act. I use a long rubber syringe made by Tiemann. The point of it is as large as the French No. 8 sound. If the opening is too small to admit this instrument at first, it can be dilated as I have before stated.

The first injection had better be mild, as the peroxide will give rise to a fulness in the head, but the patient soon becomes used to the feeling.

If a cup or a bone dish shaped like a crescent is held under the nose by the patient, the operation can be done without soiling the clothes.

I have used the above drugs and have had only partial success in the treatment of this disease; till lately I have followed up the peroxide treatment with the injection of the following preparation: ten grains of iodoform in one ounce of albolene oil. The iodoform will not dissolve in the oil; but if the bottle is well shaken, it will be held in suspension. In syringing some of the liquid will ooze into the mouth; but the most will flow down through the nose, while a sufficient quantity will remain in the antrum to cover the membrane with this perfect unguent.

At first a mild injection might be used to test the susceptibility of the patient to the iodoform preparation. If the eyes are inflamed or the nose runs very much after the treatment the strength of the solution should be diminished. If the nose should be examined after one of these injections, the mucous membrane will be found covered with the iodoform as perfectly as if it was covered with an ointment. I tried this injection on the maxillary bone covering over the apertures and found upon inspection the same appearance in the sinus.

After two or three injections of this preparation, this discharge through the ostium maxillary will have changed from its creamy pus to about the discharge that it is customary to find in hypertrophic catarrh. The peroxide will diminish the amount of the secretion; but its character will remain the same unless persisted in for a lengthened period.

The iodoform preparation will change it after a few medications. This is also true of aristol or europhen. I use nothing internally unless the patient should be debilitated. If necrosis has taken place and the patient is a syphilitic, the iodide of potash and mercury are indicated. The antrum should be syringed thoroughly once a day at the start with the peroxide and iodoform solution. If the case is one where the the pus quickly reforms, the peroxide might be used twice a day. The mistake is often made of stopping the syringing when the pus discharge has decreased and to trust to nature to perform the rest of the cure. These cases will come back in the spring or fall, and an examination of the internal nose will reveal the old pus discharge in the locality of the ostium maxillary. Keep the parts open till all sign of the pus discharge has ceased. When it is time for the opening to close, it will obliterate without any local medication.

Case I.—Male, tailor, complained that he had a discharge from the nose, he had been under treatment for catarrh before I saw the case, without any improvement. Inspection of the left nose revealed antrum disease. The discharge had flowed from his nose now for one year and over. I had the second molar tooth extracted and enlarged the opening by a steel probe. I treated the case at first with the peroxide treatment, found the discharge diminished, but the nature the same. Three weeks' treatment with iodoform allowed me to discharge my case as cured.

Case II —Female, aged twenty-six, came complaining that she was forced to use her handkerchief very often to one side of her nose; the discharge had a disagreeable odor. Inspection revealed antrum abscess. Removal of tooth and syringing with the above preparations gradually decreased the amount of the discharge and permitted me to dismiss my patient after thirty days' treatment.

The above treatment has been very efficient in the cases that have come under my charge. This mode of medication changes the character of the discharge in a short period, and if it is persisted in the case can be permanently cured.

112 West Forty-fifth Street.

Hysteria and Marriage.—The belief is as old as Hippocrates that hysteria is cured by marriage. But Dr. Wythe Cook finds, from his experience, that in most cases of dysmenorrhœa and hysteria among single women, marriage aggravates the disease. Hysteria is by no means cured by marriage, dysmenorrhœa often returns after pregnancy.—*American Journal of Obstetrics.*

ATONY OF THE STOMACH.

By M. GROSS, M.D.,

NEW YORK.

By the term atony of the stomach we understand that condition of the organ which manifests itself by relaxation of the muscular tissue, that is, a mechanical insufficiency of the stomach.

Unquestionably, the occurrence of paresis of the gastric muscular tissue, which must be looked upon not as a symptom of an anatomical alteration of the stomach-wall, but as a pure neurosis, is far more rare. In the production of dilatation of the stomach such conditions of atony play an important part, as I shall show hereafter.

These primary atonic conditions may occur as an independent disease of the innervation of the nerve centres governing the peristalsis of the stomach, whether situated at the seat of the affection or in the central nervous system, and are a frequent cause of the resulting dyspeptic troubles;[1] but in the great majority of cases atony of the muscular tissue of the stomach appears as a symptom. Thus we find weakness of the muscles either in consequence of excessive work thrown upon them, which is followed by gradual relaxation, or after insufficient nutrition of the contractile elements of the stomach wall in anæmia, chlorosis, nervous affections, debilitating acute and chronic diseases, etc.

In chronic gastric catarrh the ingesta remain for a long time in the stomach; the organ is overtaxed, and the immediate result is relaxation of the muscular tissue, *i.e.*, an atonic condition of the stomach-wall. In hyperchlorhydria, for instance, the digestion of amylaceous substances is retarded, the stomach is emptied very late if at all, and here, too, the consequences of overtaxing the organ will ensue. I have frequently found an atonic condition of the stomach in chronic malaria, which is by no means rare in this city.

The subjective symptoms complained of are mainly caused by the long retention of the food in the stomach and the results produced thereby. Thus the patients complain of a sense of fulness and premature satiety; of burning and eructations with an acid taste, either due to the excessive production of acids, or to the fermentation undergone by the food which remains long in the stomach.

In atony we not rarely find the form of vertigo first described by Trousseau (vertigo stomachalis), probably due to stretching of the gastric nerves. When the trouble is of long standing reflex effects upon the heart may occur, in the form of the well-known symptom-complex of cardiac (dyspeptic) asthma, with palpitation and irregular heart-action, probably the result of a neurosis of the vagus.

Of greater importance are the results of the objective examination. On percussion we find the stomach enlarged; but if we take into consideration how greatly the size of the stomach varies even under normal conditions, we shall ascribe to this sign a corroborative value only. Often enough I have had an opportunity of demonstrating a low position of the greater curvature without being able to find any dyspeptic symptoms. Thus many large eaters have a big stomach (megalogastria) without being troubled by any gastric symptoms. Of still greater importance, however, is it to determine the elasticity or tonus of the stomach.

Penzoldt makes the patient drink a quart of fluid on an empty stomach; should the greater curvature, which stood above the umbilicus, sink to the navel or lower, then the stomach-wall has lost some elasticity, because under similar conditions in the healthy state the greater curvature hardly ever reaches the navel.

Dehio took the view that the more relaxed the stomach-wall the sooner will even small quantities of fluid bring the inferior limit of the stomach to its lowest point. Hence he makes the patient drink half a pint of water in the erect position, and then marks the greater curvature.

[1] Ewald.

Gradually the patient is given more water in like quantities; in health the greater curvature will never pass below the navel, but in the atonic condition of the stomach the greater curvature will reach the umbilicus after one or two doses, and soon descends lower when more fluid is given.

I inflate the stomach by means of the tube devised by me,[1] and thus easily find the position of the greater curvature; its previous position having been determined by percussion. We may also ascertain the atonic condition of the stomach by demonstrating its lessened motor power.

1. Following Leube, we give a test-meal consisting of a plate of soup, a large beefsteak, some wheaten bread, and a glass of water. If remnants are found after the lapse of from six to seven hours, insufficiency of the stomach exists.

2. Ewald and Sievers have devised the so-called salol method, which is based on the fact that salol is decomposed into salicylic acid and phenol by alkaline solutions, or in the presence of the pancreatic juice, or of the microorganisms in the intestine, but remains unaltered in the stomach when its contents are acid in reaction. One gramme of salol is given with the meal, and twenty four hours later the urine is tested for salicylic acid by means of dilute chloride of iron solution; if the reaction is obtained (violet coloration of the urine) atony is present. The appearance of the salicylic acid in the urine enables us to form an estimate as to the rapidity with which the contents of the stomach reach the intestine; or, in other words, as to the muscular activity of the stomach.

Huber has determined the time limit within which the reaction for salicylic acid can be obtained in the urine after the ingestion of salol. This is said to be twenty-four hours for healthy persons, but in patients with weakened motility of the stomach may continue for forty-eight hours and longer.

The chemical examination of the contents of the stomach furnishes different results according to the prevailing conditions of the organ, but they offer nothing characteristic, and are not available for the diagnosis of the atonic state.

It is clear *a priori* that a continual variation from mechanical to chemical disturbance, and the reverse, must be present; for in proportion as the ingesta remain for a longer time in the stomach, they must react by mechanical irritation upon the glandular activity. This irritation will result in increased secretion of hydrochloric acid, which may even amount to a continual flow of the gastric juice (Reichmann). Eventually, however, decrease of glandular activity ensues, the ingesta undergo earlier and more rapid decomposition processes, whose products again act as noxious irritants upon the gastric mucous membrane, and even on the entire stomach-wall. In this way a vicious circle develops, which finally terminates in the stage of intense paresis and relaxation of the muscular tissue—that is, in atony and dilatation.

I have stated above that I have occasionally found in malarious patients, at my policlinic and in private practice, atonic conditions of the stomach traceable to the malarious dyscrasia alone; chemical examination of the contents of the stomach in these patients showed, in most cases, a decrease in free hydrochloric acid.

The course of the atonic condition of the stomach will depend altogether on the fundamental affection, and often assume an acute or a more chronic character.

According to what has been stated, the diagnosis of atony of the stomach would not be difficult. In the differential diagnosis, dilatation alone might come in question, and in this respect the course of the case would be decisive. Moreover, in ectasia the succussion sound can always be obtained, but in atony only for a short time after a meal.

Again, if we give test-suppers (after Boas) consisting of wheat-bread and butter, cold meat, and a large cup of tea, and find the next morning, on several occasions,

[1] New York Medical Journal, November 18, 1893.

that the stomach is invariably empty, we have to deal, not with ectasia, but with atony, if the other signs of this condition are present.

Finally, attention should be paid to the markedly diminished diuresis in ectasia, at least in the advanced stages, while in atony diuresis is approximately normal.

The therapeutic measures to be instituted should be adapted mainly to the fundamental affection; but frequently enough we shall be forced to treat the atony as a symptom. In that event the diet above all should be carefully regulated, so that the stomach-wall be relieved as much as possible of any strain by the quantity of food or its indigestibility. Hydriatic procedures in the form of the so-called "Scottish douche," may be used with good effect, and so may the systematic extra-ventricular or intra ventricular electrization conjoined with massage of the stomach and the intestinal canal. In the way of drugs, the extract of nux vomica might be tried in doses of from one-sixth to one-half grain.

Clinical Department.

SUPPURATION OF FRONTAL SINUS.[1]

By G. D. GREGOR, M.D.,

Salt Lake City, Utah.

I wish, briefly, to call your attention this evening to the subject of suppuration of the frontal sinuses, and to report an unfortunate experience I had with a case some months ago. From the fact that we are liable to learn more wisely from our mistakes than from our brilliant successes, and also from the fact that this subject is given but scant attention in most of our surgical works, affords me the opportunity to place before you the importance of this unusual subject.

You will remember that the frontal sinuses are two irregular-shaped cavities, of variable size, that extend upward and outward between the two tables of the frontal bone upon the vertical portion of its internal surface; that they are situated on each side of the nasal spine of that bone; that they are separated by a thin bony partition which is occasionally perforated, and that their cavities are frequently subdivided by incomplete bony laminæ. They are absent at birth, are small during childhood, are developed rapidly after puberty, and are said to be relatively larger in the male than in the female.

They communicate with the middle meatus of the nose by means of the infundibulum. They are lined with mucous membrane, which is continuous with that of the nose, an important anatomical fact in considering the etiology of the present subject. Owing to this continuity of tissue and similarity of anatomical structure, we would naturally expect that all inflammatory troubles in the Schneiderian membrane would be liable to extend into the sinuses, and this, as a matter of fact, does occasionally occur.

We can safely say that nearly all inflammatory troubles in the frontal sinuses are due to extension of inflammation from the nose, of course excepting those due to injuries or to the presence of neoplasms.

Inflammation of a suppurative nature in the sinuses may also be due to syphilis in the tertiary stage, then beginning as an endostitis.

The symptoms of inflammation of the frontal sinuses vary with the course of the disease. In acute cases we have the symptoms of an attack of cold in the head, to which may be added a feeling of weight and distention over the frontal protuberance, which the patient vainly tries to relieve by violently blowing the nose. If the inflammation becomes more intense, so that the swelling of the mucous membrane obstructs the communication with the nose, the suffering of the patient becomes greatly aggravated, due to the retention of secretions within the sinus. The pain, then, is referable to the forehead, and generally follows the distribution of the fifth pair of nerves in that locality. Sneezing, lachrymation, and suffusion of the eyes are particularly marked.

When these latter symptoms are present, we will find that the general indisposition that accompanies an attack of acute coryza becomes almost a prostration. In the chronic cases the symptoms are simply those of chronic nasal catarrh, with the weight and fulness in the forehead and the frequent attacks of catarrhal headache. This latter symptom is entirely dependent upon the involvement of the sinuses in the morbid process.

Under appropriate treatment the acute cases usually subside in a few days. The infundibulum becomes patent, the pent-up secretions are discharged, the pain leaves the forehead, and the patient gets well.

Unfortunately, however, there are exceptions to this happy termination. There will occasionally be a case in which the infundibulum does not become pervious. The secretion of muco-pus gives place to pus itself. The mucous membrane of the sinus becomes a regular pyogenic membrane, and we have the formation of an abscess, an empyema of the frontal sinuses. Some writers claim that this condition never obtains unless due to tertiary syphilis, others, that such a history is not at all necessary. My experience with one case shows that it unquestionably may occur when there is no suspicion of syphilis.

I am unable to obtain any statistics as to whether this suppurative inflammation is more liable to occur during a primary attack or during an exacerbation of a chronic condition. My own case evidently belonged to the latter type, and we would naturally infer that this generally would be the case.

When an abscess is forming we may know it by the chronicity of the case, the excessive and persistent headache, the rapid pulse, rigors followed by fever and sweating; in fact we have the same symptoms that we get when pus is forming in any situation, to which may be added the local symptoms of pain in the forehead, the local swelling and œdema, and an erysipelatous blush over the frontal protuberances. Now if prompt relief is not given to the patient in this stage, more disastrous results will surely follow. First would be caries or necrosis of the bony walls of the sinus, and second, the membranes of the brain will become involved in the morbid process, or more likely the formation of an abscess from the deposit of septic material on the surface of the brain. Whether this deposit occurs directly, from the lymphatics of the sinus communicating with those of the brain, or by first breaking through the bony partition and coming in direct contact with them, is of little importance. It is sufficient for us to know that, often, abscess of the brain follows very closely upon the inauguration of a suppurative process in the frontal sinus. A few authors state that occasionally the pus may find its way into the cavity of the nose, or by breaking down the anterior wall of the sinus be discharged externally. I have found the reports of a few cases that followed the latter course. However, they all unite in saying that no reliance can, with safety, be placed on the probability of such an occurrence.

In the treatment of the acute catarrhal types, it is only necessary to follow the same general lines that are used in an ordinary attack of coryza, such as opium, diaphoretics, the instillation into the nose of a few drops of a four per cent. solution of cocaine, to which may be added, if the symptoms point to more or less obstruction of the infundibulum, local depletion followed by warm fomentations over the frontal protuberance.

If we become satisfied that that opening is completely closed, and that we have an accumulation of mucus in the sinus, the question of mechanically reopening it should be considered. Some authors speak of it as a very simple operation. Others say it is extremely difficult, and advise us to be satisfied with local applications to the Schneiderian membrane, stating that modifica-

[1] Read before the Salt Lake Medical Society, December 18, 1893.

tion in the inflammation in one cavity will speedily be followed by improvement in the other.

When from the general and local symptoms it becomes evident that we have pus in the frontal sinuses we should not delay, but at once provide for its safe discharge. Again would come up the advisability of trying to render patent the infundibulum by means of probes and to keep it so by drainage-tubes. I must confess that it seems to me a difficult if not a dangerous operation, under such conditions, to introduce a probe into the sinus, and almost impossible to successfully introduce a drainage-tube. As it is imperative, however, that some means should be provided for escape of the pus, we will find an easier and safer method by an external opening. This is done by making an incision along the inner border of the orbit, laying the bone bare over the most dependent portion of the sinus, and then opening the sinus with a small trephine.

The cavity should be washed out with an antiseptic solution and drainage maintained. The importance of early interference, or, rather the danger of delay is only too well illustrated by the following case, which came under my observation some few months ago.

On March 27, 1893, when visiting a patient in an adjoining town, I was requested to see a lady, who, I was informed, had been suffering from neuralgia for some two months. I found the patient a large fleshy woman, thirty two years of age; native of Utah; mother of three bright, healthy children. Family history good. Nothing of importance in personal history except one mild attack of rheumatism some six years previous, and that for a few years past she had been troubled with catarrh. She stated that she was subject to occasional attacks of headache, lasting several days, and which would terminate by a profuse offensive discharge of muco-pus from the nose—"gatherings in the head," as she expressed it. Careful questioning failed to elicit any suspicion of a syphilitic taint. Her present trouble she dated back two or three months since she first began to feel badly, and have some pain in the forehead, but the intense pain did not begin until about six weeks prior to my visit. The immediate cause she attributed to taking cold while doing a washing in an open shed adjacent to the kitchen. From that time until I saw her she was too ill to attend to her household duties. There had been a a little fever, slight chilly sensations, some cough, more or less sneezing, anorexia, and prostration. Her one great cry, however, was the pain in the forehead, which she described as being constantly present and of a dull character, but at times it would become paroxysmal and radiate all over the forehead and even to the back of the head. At such times the pain was almost unbearable. She was unable to sleep except by the use of opiates. About a week before my visit the upper eyelids began to swell, occasionally the eyes were nearly closed, especially after lying down, the dependent eye being the one to swell the most. Most of her time, however, was spent in a reclining position, as the recumbent position seemed to intensify the pain. Examination showed marked œdema over the nasal eminence, extending well up on the forehead and involving both upper eyelids. The skin had a reddish blush. No indication of fluctuation and but little pain on pressure, and that following the distribution of the fifth pair of nerves over the forehead. There was a little fever and a rapid pulse. Further examination of the patient was negative. I diagnosed empyema of the frontal sinuses and advised local fomentations to the forehead, with a warm nasal douche three times daily. Constitutionally she had quinia and iron, with opiates to control pain. I explained to the family that if within a week she did not get relief, they were to bring her up to me and I would open the sinus. I also stated to them that there was some danger of the brain becoming involved on account of the proximity of the abscess to the brain tissue.

On returning to my home and looking the subject up I felt that I had not fully appreciated the urgency of the case myself, so probably had not impressed the friends of the patient with the importance of an early interference, so I immediately wrote the husband, urging him to bring his wife up so we could open the sinus at once. A few days later he reported that the abscess had the appearance of being about to break on the outside, so he would wait. Again in a few days he reported that it had broken and discharged through the nose, and that the patient was greatly relieved. Nothing further was heard from her until April 24th, four weeks from my first visit, when I was requested to see the case. I found her in a deplorable condition, prostrated, rapid pulse, and high fever. There was a large accumulation of pus over the right side of the forehead, and two others on the head, one on the right, and one on the left side. There had been delirium for two nights previous, but there was nothing to show that it was due to more than her general septic condition. I administered ether and opened the external abscesses—and I may say that the pus lay, not in the tissue of the scalp, but beneath the pericranium—washed them out and provided for drainage. I then opened the right frontal sinus by an incision along the inner border of the orbit until the bone was well exposed, and then used a small trephine. Some pus was discharged from the sinus. I washed it out and introduced a small drainage-tube. Two days later the patient had a slight convulsive attack beginning in the right leg, and involving only the muscles of the right side, that is, those of the face, arm, and leg. When I saw her the same day there was paralysis of the right leg, slight paralysis of the arm, and some difficulty in speech. There was no fever, and the abscesses on the head had stopped discharging. There was but little pus in the tube in the sinus. I gave an unfavorable prognosis and advised trephining, but further operative interference was refused.

The patient lived until May 9th, when she died very suddenly. During this time there had been but little change, except that the paralysis of the leg became absolute, and that of speech practically so, while there seemed to be a little improvement in the arm. She unquestionably suffered a great deal of pain, which she would indicate as being on the top of her head. There were no changes in the pupils and they reacted to light readily. She apparently was perfectly clear mentally. There was little or no fever, and a good pulse of about a hundred.

With the above history I think you would all agree that an abscess could have been found at the upper end of the fissure of Rolando, and another one, perhaps, over Broca's convolution. I was greatly disappointed in not being able to operate before death, and again in being unable to obtain an autopsy.

The two mistakes in the case, as you will readily see, were in not opening the sinus four weeks before it was done, and second, in not trephining for the abscess in the cranial cavity when there could have been no doubt of its presence in the location indicated above. In conclusion, then, gentlemen, permit me to say that if these few remarks and this unfortunate case have called your attention to the importance of suppuration of the frontal sinuses, I am amply repaid, and the object of this paper has been attained.

Park City, Utah, November 18, 1893.

Association of Military Surgeons of the United States.—The fourth annual meeting of this organization will be held in Washington, D. C., May 1st, 2d, and 3d, 1894. This national organization is composed of medical officers of the United States Army, United States Navy, National Guard of the United States, and the Hospital Marine Service—in whose service are many of the most celebrated and distinguished surgeons of our country. A brilliant and able literary programme will be presented. The afternoon of one day will be set apart for an object-lesson from the "Manual of Drill," by the Hospital Corps. The evening will be given up to social entertainments. There will be about five hundred delegates in attendance.

Progress of Medical Science.

Phonographic Otitis.—A new competitor for public patronage has made his appearance during the last year or so at the street corners and unoccupied shops. He is the proud possessor of a diminutive machine provided with octopus-like prolongations which hang down gracefully along its sides and ends, and its very appearance is calculated to rivet the attention of the passer-by. This is the latest form of Edison's wonderful phonograph, which, after having for years been seen little of outside scientific societies and evening parties, has now been popularized on a large scale. It cannot be denied that the entertainment is well worth the price charged per *séance*. One has only to push the xylonite extremities well into the ears, and then on touching a spring one is treated to band music, orations, humorous recitals, and the whole, or part, of a very extensive *répertoire*, as per contrast. As a means of educating and amusing the public nothing could be better, but every medal has its reverse, and the phonograph is not exempt from the common failing. Our attention was called to this "reverse" by several cases in which patients with catarrh and even suppuration of the external ear have dated the onset of the affection from their interview with the aforesaid phonograph. One hardly needs a medical education to appreciate at once the gravity of the risks incurred by pushing into one's ears a nozzle which has been used by a motley crowd, possibly only a few instants previously. When one reflects upon the very large proportion of people who suffer from one form or another of suppurative disease the danger, nay the certainty, of the transfer of the *materies morbi* is apparent. In many cases the matter thus introduced into so sensitive an organ as the ear is of such a virulent nature that no special predisposition is necessary on the part of the recipient to insure immediate irritation, followed in all probability by more or less serious local mischief. Every medical man is cognizant of the risks entailed by suppurative disease of the ear. So grave is it, even in comparatively mild cases, that life insurance companies usually hesitate to accept a proposal from anyone thus afflicted. Hence it is sufficient to call attention to the danger to insure that intelligent persons will think twice before listening to a public phonograph, though for the matter of that the risk is not materially less when the exhibition takes place in a drawing-room instead of at a street corner.—*Medical Press.*

Compression of the Phrenic Nerve.—Dr. Bidon, of Marseilles, had recourse recently to digital compression of the phrenic nerve in two cases of spasm of the glottis, imitating thus the treatment of Professor Leloir, of Lille, for obstinate hiccough. The first case observed by M. Bidon was that of a young, hysterical girl who, after a convulsive attack, was seized with spasm of the glottis so violent that her life was in danger. (*Medical Press.*) The practitioner buried his index-finger between the origins of the sterno mastoid muscle, by which means the phrenic nerve was compressed. Almost immediately the patient began to breathe, and continuing the digital pressure for the space of one minute, all symptoms had disappeared. The spasm returned at intervals subsequently, but the same treatment proved to be efficient. The second case was that of a man already suffering from ataxy. He was suddenly seized with a feeling of constriction of the larynx, and in a few seconds fell off into a semi-asphyxiated condition. The attacks occurred every ten minutes. Digital pressure of the phrenic nerve produced an immediate cessation of the spasm, but when the finger was removed it returned. However, by persisting in this treatment the man recovered completely. These cases would go to prove that the above treatment can be relied on in spasm of the glottis, but its action must be indirect, as the nerve pressed does not control the larynx.

Chloralose as an Hypnotic.—Dr. Rossi has tried the hypnotic effects of chloralose on forty patients of both sexes in the lunatic asylum of Reggio-Emilia, suffering from mental disease of the most varied forms, in all of which obstinate insomnia was present. The experiments in the forty cases make up a total of two hundred and fifty observations. (*The British Medical Journal.*) The drug was given in doses of 0.25 grain to 1 grain, sometimes in powder, sometimes in solution, and the efficacy of the remedy was tested by administration in the day-time as well as at night. Rossi's conclusions are as follows: Chloralose in the average doses indicated by Richet (0.30 to 0.40 grain) is not really useful in the case of lunatics suffering from true insomnia; in such cases doses of 0.70 to 0.80 grain and even more are generally required. Given in the daytime in the first-named doses, chloralose is not satisfactory, usually causing nothing more than drowsiness. Given at night it almost always induces sleep in from half an hour to an hour and a half, the sleep lasting a longer or shorter time, not only in proportion to the dose, but according to the idiosyncrasy of the individual. The drug is most active in forms of insanity attended with depression, and least so in those in which excitement is present, its action in the latter type of cases being inconstant and unreliable. Sleep induced by chloralose is quiet, but not generally very deep, the patients being aroused by the slightest noise, but immediately going to sleep again. The awakening does not seem to be accompanied by unpleasant sensations, but Rossi points out how difficult it is to get trustworthy information on this head from lunatics. No alterations of pulse or respiration were observed in patients under the influence of the drug; on the other hand, its action on the cerebral circulation appeared to be to increase tonicity.

Iodine and Iodide.—Dr. Mortimer Granville writes to *The Lancet*: "In an 'Analytical Record' in *The Lancet* of January 6th last, when expressing approval of a wine containing iodine, you say: 'Iodine has been sparingly employed hitherto on account of its irritant and other disagreeable properties.' If that be so, and the profession labors under the erroneous impression that iodine is productive of disagreeable or irritating results when taken in a free state, the sooner that groundless impression is removed the better. It can only have its basis in inexperience. Free iodine, as contained in the tinctures used in France, Austria, Belgium, the United States, Denmark, Norway, Sweden, Holland, Germany, Hungary, Russia, Portugal, Switzerland, and Spain, all of which are free from iodide of potassium, has, when properly diluted, no irritating or disagreeable effect, and from three to five grains can be taken, in doses of from one-half to a whole grain, daily without the slightest discomfort, by the most delicate stomach. It is the iodide of potassium that does the mischief, and why that salt was ever introduced into the 'tinctura iodi' of the British Pharmacopœia no one can divine, unless it be the sage counsellors who were responsible for rendering the present tincture perfectly useless by actually adding to the quantity of the poison with which the tincture had been previously adulterated. If only the autocrats of our medico-pharmaceutical science possessed the smallest acquaintance with practical pharmacy, or combined a smattering of therapeutical knowledge with their drug lore, it would not be necessary—as it now is—to write 'codex' after many of the commonest preparations in order that the drugs prescribed may, at least, be dispensed approximately pure. It is, however, probably hopeless to expect pharmaceutical reform while the profession of medicine in this country bows down to 'soda' and 'potass' as the two giants capable of conquering every foe they have to encounter. Perhaps the time may come when it will be 'discovered' that sodium and potassium are really the greatest enemies of health as employed by those who assume to be its preservers and restorers."

MEDICAL RECORD:

New York, March 31, 1894.

THE OWNERSHIP OF THE PRESCRIPTION.

THE question who owns the prescription has a periodical agitation. Sometimes it comes up in court, occasionally in a medical society, but oftener as one of issue between the physician and the druggist. We are reminded that there are some points connected with its solution that are not yet definitely settled, as every little while interrogatories reach us from widely different localities. This time a correspondent asks if a pharmacist should not be compelled to surrender the prescription to the physician writing it when the latter demands it; also whether the pharmacist has a right to repeat its administration in a given case against the wish of the writer of the same; and lastly, if it is not customary to respect the wishes of the physician under such circumstances.

The subject from these points of view is quite a complex one, when we take into account the number of conditions that obtain from the giving to the taking of the prescription. In a general way we may assume that there are three principal factors to be considered: the physician, the patient, and the pharmacist. In order that each should be suitably protected, a number of considerations should be taken into account. The prescription is an order on a pharmacist for drugs, which is given by the physician to a patient as part of the advice and treatment of the latter for a particular ailment at a particular time. So long as all the conditions are fulfilled in their natural sequence, with a perfect understanding of indications to be met, there never is trouble, and the entire transaction is a straightforward business one. In fact, the only interruption to the harmonious action is where a special claim is made of actual ownership of the prescription.

The question has been viewed from the respective standpoints of the physician, the pharmacist, and the patient, and much unnecessary confusion as to relative rights has thereby resulted.

If, however, we bear in mind why the prescription is written, we can the easier come to some conclusion as to the apparently mixed question of proprietorship when its real purposes are fulfilled. The physician who gives the prescription intends that it shall be used only in accordance with his directions. He is not responsible beyond this, and if the patient insists upon disobeying orders, the physician does not necessarily share the risk, or become accountable for any bad results. Hence the prudent patient follows directions as to whether or not the prescription shall be repeated. In an equitable sense, it is the patient's property only in so far as it can serve the specific purpose for which it was given. When such conditions have been met, the prescription ceases to be as such; and practically, as far as either prescriber or patient are concerned, it has no more existence than if it had never been written. When the patient is no longer in need of it medically, and persists on his own account in repeating the prescription, he is appropriating that which, professionally speaking, does not belong to him, and he does a still greater wrong when he gives it to another whom it may seriously harm, and then the new man who takes the medicine is the bigger fool of the two.

But just here the pharmacist is generally the culpable go-between. While there is no law to prevent a patient repeating a prescription as often as he pleases, it is ethically wrong for the compounder to allow him to do it. The prescription is not in any sense so much the property of the druggist that he can do what he pleases with it. It is simply a particular order for drugs, and can in no proper sense be used as a general one on demand by any would-be customer. The pharmacist places the prescription on file as a legal evidence that he has fulfilled a special contract. It is, in fact, his only protection against subsequent damages arising from alleged inaccuracy in compounding, or mistakes in the selection of ingredients. But he owns it as a voucher only, and cannot legitimately use it for any other purpose. Consequently, when he attempts to do otherwise he is in every way transcending his functions, and acting most unjustly to both physician and would-be patient. If such is granted, the questions arising in connection with the whole matter are simple enough, and appeal to the good sense of all parties concerned.

It has been legally held by several judges in this and other States, that the proper owner of the prescription is the pharmacist. He is responsible for its proper compounding and has a right to it as a voucher. There is no law to prevent his repeating it in any manner he chooses, and the patient, or anyone else, can buy the compound of which it is the order if the druggist chooses to sell the same.

If the mixture contains any poisonous ingredients, or the patient can claim to have been damaged by taking it, the compounder is liable for damages as a seller of poisons without license. The patient, however, is a free moral agent up to the point of attempting to commit suicide by taking a poisonous drug. In case of any serious perversion of the original intent of the prescription, both parties in the action are culpable and take any extra responsibility at their peril. In ordinary cases, however, no legal interference is contemplated. If a druggist recommends the prescription to a stranger, he virtually attempts to give him medical advice, which opens him to the charge of practising without legal authority.

Unfortunately, there is no remedy that will legally fit such unprofessional usages. The physician has no power to insist upon a return of his prescription or forbid its indiscriminate use, save on purely professional grounds of common courtesy. When the prescription is given to the patient it is virtually beyond the prescriber's reach. The patient having paid for it as part of the advice given, claims the right to use it for himself as often as he sees fit, and can with the druggist's consent secure a copy of it for such purposes. It is usual, however, for the pharmacist with a proper moral sense to respect the wishes of

the prescriber, and when he does not do so, it is also customary for the physician to obviate the necessity of having any difference of opinion upon the subject in future by advising the patient to patronize some other shop. Very often, too, the physician retaliates in kind by furnishing his own medicines whenever suitable opportunities offer.

THE ENGLISH OF THE CONGRESS.

An International Congress Bulletin, printed in the three or four official languages, is usually more or less amusing through the efforts of its editors to grapple with the intricacies of the English tongue, but the Rome Congress, determined to be outdone in no particular by its predecessors, has earned the palm for maltreatment of our poor speech. The preliminary documents were not so bad, but in the first issue of the Official Journal under date of March 10th, the editor has warmed up to his work, and handles the English column in a way that would bring a blush to the cheek of the author of "The English as She is Spoke." As a specimen of the many gems with which this learned publication sparkles, we take the order for one day. "Thursday, 29th March—10 hour: Inauguration of the Congress at the presence of their Majesty to the Costanzi Theatre.—General Assembly of the Congressist for the constitution of the Chairman definitive office.—15 hour: Adunance of the Sections for the definitive constitution of the offices.—21 hour: Illumination of the Platea Archeologica."

This is entertaining enough once in a way, but when it is repeated in nearly every line through four pages, it becomes wearisome. There is no excuse for such wholesale murder of English in these publications, especially in Rome where there are numbers of English and American students, and residents who would gladly see to it that the language of the bulletins was rendered intelligible to their medical compatriots. English is the leading language of the civilized world, and it is entitled to demand respectful treatment at the hands even of the editor of a Medical Congress Bulletin.

CHEAP INFANT FOODS.

The subject of infant foods is one of perennial interest; and it is one upon which much more work must be done before a satisfactory solution of the problem has been reached. There seems to be no doubt that the number of artificially reared infants is increasing. A large proportion of women of the wealthiest classes cannot or will not nurse their children. Good wet nurses are difficult to obtain, and are a nuisance at the best.

In the search for a perfect infant food one point has at least been gained. It is acknowledged that no single formula or compound will answer exactly the purposes of human milk: for this latter is a constantly varying secretion. Hence physicians recognize now that the food for every baby must be changed somewhat, according to its age, size, and digestive susceptibility. In a recent address before the Pan-American Congress. Dr. T. D. Rotch says:

"There is no mammal whose milk-production corresponds sufficiently to human milk to render a direct substitution safe or wise. If, therefore, milk is used, the problem demands for its solution a modified milk. The mammal whose product representing a carnivorous food has been proved from the earliest age to best satisfy this demand is the cow."

There is no doubt that several of the infant foods now on the market, if properly administered, can be substituted efficiently for human milk. But among the poorer classes, the expense attending the use of these foods is a great tax. Dr. H. D. Chapin, and Dr. S. Eiloart have undertaken a series of experiments for the purpose of obtaining a cheap substitute for human milk, using cow's milk as a basis. Dr. Chapin advises against the complete sterilization of city milk, but thinks that its partial sterilization or pasteurization is necessary in order to kill the microbe of lactic acid fermentation. The milk used is the ordinary cow's milk of the city, which is twenty-four to thirty-six hours old. This is allowed to stand, and the upper half only used. This contains, according to Drs. Chapin and Eiloart, 4.9 per cent. fat, as against 3.03 per cent. in the lower half. The object sought for by the investigators was to secure some diluent for the milk which would properly enrich it, and at the same time prevent its coagulation in large tough curds. For this purpose the milk is diluted with barley, oatmeal, or wheat flour gruel, and then diastase in the form of malt added. The results obtained from the use of this food on thirty seven cases were good. The special directions for making the food are as follows:

Recipe I.—*Materials.*—Wheat flour or barley meal, two ounces (two tablespoonfuls heaped as high as possible); water, fifty-six ounces (a quart and three-quarters); extract of malt, half a teaspoonful or a small teaspoonful.

Process.—With thirty ounces (a scant quart) of the water make the flour into a gruel, boiling ten minutes in a double boiler. Take out the inner vessel and add the rest of the water cold, the malt extract being dissolved in the last few ounces added. Let it stand fifteen minutes. Put back the inner vessel and heat again in the double boiler fifteen minutes. Strain through a coffee strainer of wire gauze.

If for any reason it is desirable, and in cases of diarrhœa, to give a smaller proportion of maltose, the following recipe is used, and we get a food containing only one-fourth of the solid matter in the form of maltose:

Recipe II.—*Materials* as in Recipe I. Proceed as before, but reserve only one pint of the water for adding cold. After adding the cold water with the malt extract dissolved in the last few ounces of it, let it stand only three minutes instead of fifteen minutes. Then heat ten minutes in a double boiler and strain.

To make the gruel well and quickly, beat the flour with very little water. A little beating with little water is better than much beating with much water. Beat smooth, therefore, while the paste is still almost a dough; then add cold water to make a thin paste, and to this add the rest of the first part of the water boiling hot, with stirring. If these directions are followed, very few lumps will remain on the strainer; in fact, only about five per cent. of the meal need be lost in this way. The water in the outer vessel of the double boiler must be kept boiling throughout. Whichever recipe is followed, the food should be taken mixed with milk.

The Bill of the Quarantine Committee of the Academy of Medicine is meeting general approval in both lay and medical journals.

OFFENDERS BROUGHT TO BAY.

New York should be proud of her distinctive freedom from charlatans in medicine, as compared with many quack-infested cities. The profession is proud of it, and it is just this commendable pride which causes us now to rejoice in the arrest and imprisonment of no less than sixteen individuals, ten being of the softer sex, who are charged with illegal practices having to do mostly with their efforts to keep down population. It may be true that we suffer from overcrowding, that there are too many unemployed starving mortals already here; but the performance of abortion without necessity for the act, has been made illegal, and so long as this view continues to be held by legislators, the glaring advertisements of these specialists in crime must disgust honest men and disgrace the community which tolerates them.

Superintendent Byrnes and the Society for the Enforcement of Criminal Law deserve all praise for their timely and fruitful activity and well-planned raid, and it is greatly to be desired that the courts do their part as well in putting a stop to this violation of the law. Four at least of the men arrested are registered practitioners, three being put down as graduates of eclectic schools, and therefore cannot be held for practising without diplomas, as it is probable most of the women can be; but it is to be hoped that Mrs. Fox, the agent of the Society, obtained sufficient evidence in the detective part played by her to secure conviction of all guilty persons.

MEDICAL BUCCANEERS.

If the *Medical and Surgical Reporter* has not overdrawn the picture, the medical profession is at present suffering from the depredations of "buccaneers" within its own ranks. Our contemporary is much exercised over this lamentable state of affairs. It asserts that to talk of amending codes, or instituting reforms, or improving the status of the profession while this insatiable gourmand is allowed unfettered liberty is a travesty on reason. He plays his part in manifold ways. He often roams in high places, and may even wear a professor's gown. He looms up at medical conventions, and, indeed, may be an author of no mean position. He is always clamoring for reform; he wants to reform the code, let down the bars and clear the way so that his pilfering career may be unhampered. His neighbor stands in mortal terror of him, because he well knows that should he be required to call him in consultation the new arrival would quickly oust him and coolly take possession himself. He performs impossible operations, and always cures every case, and the unsuspecting, simple minded, honest plodder, as he reads his statistics, is quite overcome with amazement and admiration. He has a sneaking way of advertising. To go into the regular column of the quacks would be to mix with the common herd; moreover, it is highly expensive; therefore he has himself interviewed, or one of his helpers will see to it that, while the great man speaks, full stenographic notes are taken, and the thing, highly colored, will be spread broadcast in the early morning press.

Continuing its diatribe the *Reporter* says that the dragnet of the pirate is so far spread out that he leaves almost nothing for the honest plodder. From year to year he becomes more and more bold, and finally having duped and bulldozed his professional brethren, he turns his attention to lay people, before whom his hideous hypocrisy is supported by consummate strategy. He wants to raise funds for a ward "for the poor, you know," run soirées, parties, etc., until a necessary sum is wrung out of the pockets of the unsuspecting. Then he suddenly blooms out a specialist, and now that he is safely entrenched behind his own walls, in his zeal for patients his audacity is villainous, for through the mails he is a constant intruder, incessantly appealing to practitioners to send to him that which they themselves depend upon for their living.

It is not for us to say that the medical buccaneer is a mere figment of an excited fancy. But the danger to the profession at large from his wholesale pillage is hardly as great as we are asked to believe. We are disposed to place credence in what may be termed "petty pilferings" by enterprising medical adventurers. But in New York, at least, the grand larceny of pay-patients is of rare occurrence. Medical men, even of the dangerous consultant type, who habitually appropriate the patients of others, soon get to the end of their tether. Buccaneering does not flourish here, if for no better reason, simply because it would not pay.

REGISTRATION OF THE TUBERCULOUS.

The action of various State and local Boards of Health in regard to the subject of tuberculosis is one of transcendent interest. It marks a new era in sanitation, and means that as years go by tuberculosis will gradually become less and less a scourge, if not actually extinct. A disease which kills twelve per cent. of the population is something that it is worth while to try and abolish.

The New York State Board compels the registration of all tuberculous persons, but does not attempt sanitary visitation and disinfection except under certain conditions. The Philadelphia Board does not require registration, but simply attempts an active educational campaign in the matter of preventing the disease.

MEDICAL WIVES FOR MISSIONARIES.

"Murdered Millions" is the attractive title of Dr. George D. Dowkoutt's book just published to demonstrate the lack of medical care in heathen lands, and to point out the necessity for medical missionaries.

The deplorable ignorance of those who attend the sick and injured in many portions of the globe, and the horrible barbarities inflicted under the name of medical practice, are almost past belief. The Church has already recognized the necessity for ministering to the bodily pains while it strives to heal the soul, and although much has been done already, it is as nothing when compared with the millions who know no scientific medicine. We have but one little suggestion to offer. The young man preparing himself for missionary work requires a long time in theological study. He should also secure a wife to share his lonely lot. Why not pick out his future companion when he enters the seminary, and let her begin a course at a medical school. While he studies to save a life for the hereafter, she will learn how to save it for the here; and then, without loss of time, but filled with knowledge and that contentment which can only come from a noble purpose, they will sail the seas

together in quest of barbarous tribes to teach the better way.

Then will come a time when calomel will reach the spot in the benighted Arab more quickly than the swallowed verse from the Koran. Then will the Korean maid know better than to let them cut off her good right hand to make a broth for her expiring sire.

SKILLED LABOR AND HIGH FEES.

It is quite gratifying to learn that Dr. Galesowski, an ophthalmologist of Paris, is to receive thirty-five thousand dollars and extra expenses for an operation to be performed on a member of the family of the Shah of Persia. We are not informed of the nature of the trouble requiring the skill, but anything from a truant and trickling tear to a ripe and full grown cataract is a good compass for such a fee. We congratulate the lucky ophthalmologist accordingly, and indirectly felicitate his numerous friendly, if not envious, *confrères* in this and other countries. We will not say that the service is not worth anything that can be obtained for it. In fact this rule applies to all skilled manœuvres, and is the proper equitable basis for the estimation of all first-class professional work. There should be no limit for maximum fees beyond the possibility of their being paid by persons abundantly able to do so. Otherwise, how is the operator to be repaid for the time, hard work, and ever-present anxiety as to results of his ventures, which form so much of his dearly bought experiences. His ultimate success is bought only at the expense of countless disasters, numerous mortifications, and silent worries, and yet a particular operation is too often regarded by the patient as having a standard marketable value which can be absolutely measured by the figures on a check. But every operator who has had the dreadful misgivings which come in the line of chances defiantly and desperately taken, knows full well that the real strain is more than the actual work, and that there are many things to the man who must do and dare, that cannot be paid by any amount of moneyed considerations.

CHLOROFORMING IN SLEEP.

It is becoming fashionable for burglars to chloroform their victims in the hope that their work will be the more easily and effectually done. As the plan is to administer the anæsthetic while the patient sleeps, it is no wonder that failure attends the effort. Happily it is one of the most difficult feats to accomplish, requiring the greatest care and the highest degree of skill. By many good observers it has been claimed to be impossible. The latter may be looked upon as the rule, especially with novices. Before primary insensibility is obtained the victim awakes from the irritation of the inhaled vapor when force is necessary for the completion of the purpose. In the meantime the alarm may be given and the assailant may be captured. Fortunately the chances are always against the latter, as his victim, facing the horror of strangulation, is instantly and almost instinctively roused to desperate resistance. Taking all the chances, however, chloroform in the hands of a burglar should be considered as dangerous to his victim as a club, an axe, or a bullet, and its administration should be punished to that extreme limit of penalty which is due to the employment of other murderous measures.

News of the Week.

Congress of American Physicians and Surgeons—Third Triennial Session.—The Congress meets in Washington, D. C., May 29th to June 1st, inclusive. It is composed of the members of those National Medical Societies whose names and Secretaries are given below, and of guests specially invited by the Executive Committee. To enable a physician residing in the United States to become a member of the Congress, with the right to participate in its proceedings, it is necessary that he be a member of one of these Constituent National Societies. A physician may be accredited as a visitor to the Congress by any one of the Constituent Societies. The certificate of the Secretary of one of these societies, to the effect that he is thus accredited, will enable him to register upon payment of the registration fee, which registration will entitle him to a card of admission to the Reception and to a copy of the Transactions of the Congress, but not to take part in the deliberations of the Congress. The following are the names of the Constituent Societies in the order of date of their organization, and the names and addresses of their respective secretaries, to whom inquiries, as to mode of obtaining membership, should be addressed: American Ophthalmological Society, Secretary, S. B. St. John, M.D., Hartford, Conn.; American Otological Society, Secretary, J. J. B. Vermyne, M.D., New Bedford, Mass.; American Neurological Association, Secretary, Græme M. Hammond, M.D., 58 W. Forty sixth Street, N. Y. City; American Gynecological Society, Secretary, H. C. Coe, M D., 27 E. Sixty-fourth Street, N. Y. City; American Dermatological Association, Secretary, Charles Warrenne Allen, M.D., 640 Madison Avenue, N. Y. City; American Laryngological Association, Secretary, Charles H. Knight, M.D., 20 W. Thirty-first Street, N. Y. City; American Surgical Association, Secretary, J. R. Weist, M.D., 118 N. Eighth Street, Richmond, Ind.; American Climatological Society, Secretary, J. B. Walker, M.D., 1617 Green Street, Philadelphia, Pa.; Association of American Physicians, Secretary, Henry Hun, M.D., 33 Elk Street, Albany, N. Y.; American Association of Genito-Urinary Surgeons, Secretary, J. A. Fordyce, M.D., 66 Park Avenue, N. Y. City; American Orthopedic Association, Secretary, John Ridlon, M.D., 103 State Street, Chicago, Ill.; American Physiological Society, Secretary, W. P. Lombard, M.D., Ann Arbor, Mich.; Association of American Anatomists, Secretary, D. S. Lamb, M.D., 800 Tenth Street, Washington, D. C.; American Pediatric Society, Secretary, Samuel S. Adams, M.D., 1632 K Street, Washington, D. C.

The New Medical Practice Law in Connecticut.—The first semi-annual examination under the provisions of the new medical practice law was held last week in New Haven. Eight candidates were examined by the committee appointed by the State Board of Health, and only five were given certificates.

The First and Most Noted and Most Approved institution for the applied therapeutics of crime, at the Elmira Reformatory, has been declared a failure, and its Board of Managers is requested to resign. The State Board of Charities has made its report, and recommend

that corporal punishment, as practised in the Reformatory, should be prohibited by law.

Utilizing High Animal Temperature.—A woman, in Ohio, utilized the high temperature of her phthisical husband for eight weeks before his death, by using him as an incubator for hen's eggs. She took a number of eggs and, wrapping each one in cotton batting, laid them alongside the body of her husband in the bed, he being unable to resist or move a limb. Fifty was the number of eggs first used as an experiment, and after three weeks she was rewarded with forty-six lively young chickens. The happy result of the first trial prompted her to try it again, and this time she doubled the quantity, and was again rewarded for her ingenuity with another brood of chickens. Another hundred eggs were placed in the bed, but this time her husband was so near the end that the necessary heat was lacking, and he passed away leaving behind one hundred half-hatched chicks. The scheming wife, not to be outdone in her plans by grim death, placed the eggs in the oven, thinking to finish the work her husband had failed to complete. During the bustle and excitement of the funeral, however, she allowed the fire to get too hot, and the eggs were all cooked. It is to be hoped that there is no incubator awaiting her in this world at least.

Death of Dr. John H. Rauch.—Dr. John H. Rauch, of Chicago, formerly president of the Illinois State Board of Health, was found dead in bed at the residence of his brother, Cyrus G. Rauch, of Lebanon, Pa., March 25th. Dr. Rauch was a prominent member of the Loyal Legion and of the American Medical Association, a recognized authority on medical education, and one of the most eminent sanitarians in this country. He organized the Board of Health in Chicago and was president and secretary of the Illinois State Board of Health from its organization up to 1891. He was a delegate to the International Medical Association at Berlin in 1890, and to the Pan-American Medical Congress in the City of Mexico. During the war he was brigade surgeon under General Augur, assistant medical director of the Army of the Potomac, and medical director of the Gulf Department of the Nineteenth Army Corps.

Death of Dr. Dwight Russell.—Dr. Dwight Russell died in Milford, Mass., March 25th. He was seventy-four years of age, was born in Madison, N. Y., and was graduated from the Central Medical College in Syracuse, where he was a member of the faculty from 1850 to 1854.

Hackensack Hospital, New Jersey.—The annual reception of the Board of Governors of the Hackensack Hospital was held at the Opera House, Monday evening, March 26th. Dr. David St. John, President of the Medical Board, received with the governors. There was a large attendance of representative citizens and medical men.

The National Health Bureau Bill.—The advocates for the establishment of a National Health Bureau were given a hearing on March 28th, at Washington, D.C., by the Committee on Interstate Commerce, to whom the bill was referred by the House early in the session. Short addresses in favor of the bill were made by Drs. T. Gaillard Thomas, Richard H. Derby, J. H. Girdner, George F. Shrady and T. Mitchell Prudden, of New York, Professor William H. Welch, and President Gilman, of Johns Hopkins University, and by Dr. Rohé, of Baltimore, representing the National Bureau of Health Committee of the Medico Chirurgical Faculty of Maryland. The speakers were most attentively heard by the Congressional Committee, and much interest was manifested in the purposes of the bill.

Fellow of the Edinburgh Obstetrical Society.—Dr. David D. Jennings, of this city, has been honored by election as a Fellow of the Edinburgh Obstetrical Society in recognition of valuable contributions to the pathological condition of the new-born.

Socialism and the Sale of Drugs in France.—M. Jules Guesde, the socialist deputy, intends bringing before the Chamber of Deputies the question of municipal dispensaries for the purpose of providing the poor population with medicine at cost price. The municipality of Roubaix has three times voted that such dispensaries should be organized, and each time the prefect has vetoed the vote. The municipality in question has appealed to the Conseil d'État, which declares that the Assistance Publique can distribute medical and pharmaceutical aid to any extent, and no one has a right to prevent it. The *Journal de Médicine* argues that on legal grounds municipal dispensaries cannot be opposed, if they are organized and directed according to the laws relating to them. The pharmaceutical profession is not the only one that is threatened by state socialism. The new law on medical practice which has been passed will soon be supplemented by another concerning rural medical help, which will place medical men in the position of government servants, like priests and schoolmasters.

St. Luke's Hospital, New York.—The competitive examination for positions on the house-staff of St. Luke's Hospital will be held at the hospital on Wednesday, April 18, 1894. Applications must be personally made to Rev. George S. Baker, D.D., Pastor and Superintendent, at the hospital at any time before April 14th.

The Genius of Billroth.—"Talent," according to a famous definition, "does what it can; genius does what it likes;" and the mighty surgeon, says *The Lancet*, whose loss the whole medical world is deploring was undoubtedly a genius. His mental vitality and energy were literally unbounded. The scientific and the artistic—the analytic and the creative—were faculties not only coexisting in him, but actually independent, owing their vigor and their outward expression or productiveness to the harmony with which they were kept in play. From the temporary exhaustion of one he would pass with renewed life to the exercise of the other, and be all the fresher for the alternation. After hours spent in the bacteriological laboratory he would sit down to the piano forte and dream over the keys for hours more, the intensity of his previous occupation seeming to lend a profounder sentiment or a more aërial spirituality to his interpretation of sonata or nocturne. "Billroth," his pupils have been heard to say, "was never better in the operating theatre or lecture room than after he had been assisting till the small hours at a dramatic representation or a concert in his own house." The severer the work awaiting him on the morrow the more deeply he would plunge into its emotional or intellectual opposite the night before, and *vice versâ*. Billroth was not only a musician, but an accomplished artist and litterateur.

Reviews and Notices of Books.

THE NARRATIVE OF A BUSY LIFE: AN AUTOBIOGRAPHY. By ARTHUR HALL HASSAL, M.D. Lond. Pp. 82. London and New York: Longmans, Green & Co. 1893.

THIS is a personal narrative of the work and experiences of the author during an eventful career as sanitarian, hygienist, and food analyst. A great deal of useful information is incidentally incorporated in the work, and leads the reader, insensibly perhaps, to combine amusement with scientific profit. The author thus cannot be grudged the pleasure he took in telling his short but simple story.

CHEMISTRY AND PHYSICS. THE STUDENT'S SERIES. By JOSEPH STRUTHERS, Ph B., Columbia College School of Mines, New York, and D. W. WARD, Columbia School of Mines, and CHARLES H. WILLMARTH, M.S., N. Y. 12mo, pp. 288. Philadelphia: Lea Brothers & Co.

THIS is uniform with the series edited by Dr. B. B. Gallaudet, and is upon the same general plan of questions and answers. It is well arranged, practical, and consequently useful.

TRANSACTIONS OF THE AMERICAN SURGICAL ASSOCIATION. Edited by DE FOREST WILLARD, M.D, Recorder. Vol. XI., pp. 372. Philadelphia. 1893.

THIS volume is full of material interesting to the practising surgeon, but does not present a variety equal to that which has appeared in the previous ones. The articles by Warren, Senn, Willard, Park, and White more than redeem the work.

OUTLINES OF OBSTETRICS. A Syllabus of Lectures delivered at the Long Island College Hospital. By CHARLES JEWETT, A.M., M D., Professor of Obstetrics in the College. 12mo, pp. 264.

THIS is a very practical little book for the student and practitioner, and extends over a reasonably wide field of obstetric work. It is written in a concise style, and its teachings are evidently founded on experience and are consequently useful and to the point.

THE UNIFORM SYSTEM OF ACCOUNTS, AUDIT, AND TENDERS, FOR HOSPITALS AND INSTITUTIONS. By HENRY C. BURDETT. pp. 76. London: The Scientific Press. 1893.

THIS volume is especially valuable for the use of those about to open a hospital, and gives full directions as to how accounts, etc., ought to be kept. Sample pages for the various necessary office books are given, and also from ward-books, diet-sheets, etc. Though everything is ruled to conform with English currency, the ideas are easily understood and the forms outlined could be adapted to American hospitals and asylums with very little trouble.

MANUAL OF PHYSICAL DIAGNOSIS FOR STUDENTS AND PHYSICIANS. By JAMES TYSON, M.D., Professor of Clinical Medicine, University of Pennsylvania. Pp. 241. Philadelphia: P. Blakiston, Son & Co. 1893.

THE present edition is the second of this manual, which contains certain additions and improvements. A valuable "Appendix" includes several subjects of great clinical value, as examination of blood, bacilli, stomach contents, directions for making autopsies, etc. The various instruments required for all these purposes are fully described. It is very complete, yet concise.

THE ART OF MASSAGE. By A. CREIGHTON HALE. Pp. 139. London: The Scientific Press. 1893.

THE author is a masseur, and like everyone of his craft has been impelled to write a book, dedicated to "my former pupils," etc. The pages abound in loose statements of all sorts. What they contain of real value has been printed twenty times before.

ESSENTIALS OF HOMŒOPATHIC MATERIA MEDICA. By W. A. DEWEY, M D., Late Professor of Materia Medica, Hahnemann Medical College, San Francisco. Pp. 269. Philadelphia: Boericke & Tafel. 1894.

THIS quiz compend is intended as a "guide to that grand edifice, now a century old, the homœopathic materia medica." We have read it with considerable interest, for if it is true the vast majority of medical men are still in the gall of bitterness and the bonds of iniquity. After reading that the "natrum mur. patient has a mild, tearful disposition, aggravated by consolation, while the pulsatilla patient seeks consolation," we unhesitatingly enroll ourselves under the banner of pulsatilla.

MORBID GROWTHS AND SPOROZOA. By J. JACKSON CLARKE, F.R.C.S., Curator and Pathologist to St. Mary's Hospital. London: Baillière, Tindall & Cox. 1893.

THESE essays have already appeared in the "Transactions of the London Pathological Society," but their great importance fully justifies their publication in a separate volume. It is not too much to say that they chronicle a new era in pathological research. Of course most of the information they convey is not as yet of practical value in the management of neoplasms, but they are the pioneer's axe clearing the forest, which broad roads will soon traverse. A large number of well-executed wood-cuts illustrate the text.

ATLAS OF HEAD SECTIONS. FIFTY-THREE COPPER PLATES OF FROZEN SECTIONS OF THE HEAD, AND FIFTY-THREE KEY PLATES WITH DESCRIPTIVE PLATES. By PROFESSOR WILLIAM MACEWEN, M.D., Glasgow. New York: Macmillan & Co. 1893.

THE increasing interest in brain surgery has made it incumbent upon anatomists and surgeons to study more carefully than before the mutual relations of the head and the brain. Within the past three years several valuable contributions to regional anatomy have appeared, those by Professor Albert Adamkiewicz, of Vienna, and Dr. Alexander Frazer, of Edinburgh, and by Professor Cunningham, of Dublin, being the most noteworthy.

The present volume just issued by Dr. Macewen surpasses all others, however, in perfection of its execution and in the completeness of the work. Other writers have contented themselves with representing diagrammatically, or by models, or by means of composite photographs in which successive series of dissections were displayed, the various relations which they desired to show. Dr. Macewen, however, has adopted what must be considered as the most perfect of all methods, that of a series of sections. In his introduction he says: "These sections have been made through the frozen head. The plates show the relation of the various parts of the brain to the exterior of the skull, thereby affording a great aid to cephalic topography. The form of the brain thus seen *in situ* differs in many respects from that presented by the brain removed from the skull and placed upon a flat surface. Even the processes of removal of the brain from its accurately fitting case, in which it is surrounded by a fluid medium, destroys its symmetry; and when, after removal, the soft cerebral substance is exposed unsupported, it sinks by its own weight and becomes flattened and distorted." The actual relations of the brain and skull are perfectly preserved in a frozen section, and thus these sections afford a most reliable guide to the surgeon in operations upon the brain. "The surgeon who is about to perform an operation on the brain has in these cephalic sections a means of refreshing his memory regarding the position of the various structures which he is about to encounter. At any spot which he may select for his operation he has the relations of the various parts of the brain to the outside of the

skull exposed in three different series of sections—coronal, sagittal and horizontal."

There are twenty-four coronal sections, eleven sagittal sections, and eighteen horizontal sections shown in the plates. The varying relations at different ages have been demonstrated in the coronal and horizontal sections, so that the differences in size of the brain in the child and adult have not been overlooked.

There are a number of facts of regional anatomy to which attention has been drawn in the brief introduction of the work, which may be mentioned. The way in which the frontal lobes dip downward near the mesial line in front, thus bringing them in close proximity to the ethmoidal cells and nasal cavity, is well shown in the coronal sections. The proximity of the nasal recess to the intra cranial structures suggests an easy access for erosive infective processes. The relations of the structures in and about the temporal bone to the temporo sphenoidal lobe are admirably shown, both in the coronal and horizontal sections. The difficulties of access to the brain through the mastoid region, and the comparative ease of reaching a temporo-sphenoidal abscess through the squamous portion of the temporal bone, becomes very evident on inspection of the drawings. The relations of the cranial nerves, especially the third and sixth nerves, to the base of the brain are most beautifully displayed. Another fact which is made clear is the great difficulty of reaching the cerebellum in any operation undertaken to remove from it tumors or abscesses.

This atlas should certainly be in the hands of every surgeon who aspires to enter the field of brain surgery, as a careful inspection of these plates will teach more than many volumes written upon the subject. The work has been issued as a sort of essential aid to the understanding of the author's recent work upon the "Surgery of the Brain and Cord," in which he discusses the pyogenic infective diseases of the brain, namely, meningitis, abscess of the brain, and thrombosis of the intra-cranial sinuses, and the surgical procedures for their relief. That volume will be reviewed elsewhere. The atlas presents a contribution to anatomy of even greater value than the volume mentioned. The plates themselves have been executed with the greatest care, the illustrations being very fine photogravures from photographic plates, about two thirds of the actual size of the head. The appearance of the book is a credit both to the author and to the publisher.

Abnormal Man. Essays on Education and Crime, and Related Subjects. By Arthur McDonald, Specialist in the Bureau of Education. Pp. 445. Washington: United States Printing Office. 1893.

This volume, while of interest only to a certain class of specialists of medicine, is to them of great value. The general subjects of criminology, and criminal sociology, are fully discussed, and then come chapters on Alcoholism, Insanity, and Genius, etc. Over half of the book is occupied with an elaborate bibliography of the topics treated. Many valuable statistics are also incorporated in the various sections. We have only praise for the careful industry with which the work has been compiled, and hope that the Government will give it a wide distribution.

Manual of Bacteriology for Practitioners and Students, with Especial Reference to Practical Methods. By Dr. S. L. Schenk, Professor Extraordinary in the University of Vienna. Translated from the German (by the author's permission). With an Appendix by W. R. Dawson, B.A, M.D., University, Dublin, Late University Travelling Prizeman in Medicine. With 100 Illustrations, partly colored. Longmans, Green & Co., London and New York. 1893.

Professor Schenk's excellent handbook of practical work in bacteriology has been creditably translated, and an appendix has been added in which are discussed "Vaccination against Asiatic Cholera," "Parasitic Protozoa" (in carcinoma, Darier's and Paget's diseases, mycosis fungoïdes, etc.), "The action of light upon micro organisms," and some additional methods and formulæ. The time is so short, however, since the original appeared that there has been little to add in the way of confirmed discoveries. In this work elementary technique receives special attention, and in it the student entering upon the study of bacteriology has a faithful guide. Bibliographical references are avoided, and their space is taken up with as ample details of practical points as may be. Many of the illustrations are excellent, but some could be improved upon.

A Handbook of Ophthalmic Science and Practice. By Henry E. Juler, F.R.C.S., Ophthalmic Surgeon to St. Mary's Hospital, etc. Second Edition. 8vo, pp. 549. Philadelphia: Lea Brothers & Co. 1893.

This admirable work comes to us in a second edition, improved in many details and well abreast with the advances made in ophthalmology. The general plan of the work remains the same as that of the first edition, the different ocular diseases being treated in the natural order of affections of the lids, lachrymal apparatus, conjunctiva, cornea, sclerotic, iris, ciliary body, choroid, optic nerve, retina, lens and visual field, amblyopia and errors of refraction. The errors of refraction are treated with exhaustive thoroughness, and leave nothing to be desired by the advanced student of ophthalmology. The illustrations are admirably presented, are in good number, and are well selected.

Physiology Practicums: Explicit Directions for Examining Portions of the Cat, and the Heart, Eye, and Brain of the Sheep, as an Aid in the Study of Elementary Physiology. By Burt G. Wilder, B.S., M.D., Professor of Physiology, Vertebrate Zoölogy, and Neurology in Cornell University; formerly Professor of Physiology in the Medical School of Maine; President (1885) of the American Neurological Association and of the Biological Section of the American Association for the Advancement of Science, etc. Roy. 8vo, 70 pages of Text, with Twenty seven Plates. In a Portfolio. Ithaca, N. Y.: Published by the Author. 1893.

Dr. Wilder's simple and direct method of instructing students is well displayed in this portfolio of practicums, which is the outcome of several years of development of plans for teaching large classes of general students. About ten years ago the members of the general class in physiology at Cornell University, were taught from alcoholic specimens, while brief directions in explanation were drawn upon the blackboard and orally amplified. A little later these directions were written upon cloth sheets that were suspended before the class while specimens were being studied. The directions, together with drawings of specimens, are now comprised in the present series of pamphlets and plates, which are published in portfolio form. The directions are simple, yet very complete. The use of the text is facilitated by the large size of the type and by an excellent method of spacing paragraphs. The printing of the plates on separate manilla cards enables the student to arrange two or more at a time for inspection without turning leaves—the utility of the plan being apparent. As much information as is contained in Dr. Wilder's portfolio of practicums should be required for admission to universities, and this would allow instruction to begin upon a foundation both higher and more substantial than at present. Some of the elementary text-books already embrace "practical work" covering nearly the same general ground as the "Practicums," but with less detail and commonly without figures, which in this portfolio are almost as good as object-lessons.

The real bars to the personal examination of the heart, eye, brain, etc., in the schools, are the scarcity of competent teachers and the imaginary difficulty of providing the requisite material; but Dr Wilder's forthcoming work on directions for preparing specimens for the "Physiology Practicums," will probably do away

with the latter difficulty. Many of his students become teachers, but while the supervision of an instructor may be necessary to enable the beginner to advance with a feeling of confidence, the directions contained in the portfolio of text and plates are so full, and the terms are so free from ambiguity, that any ordinary student can easily understand and follow them.

An Outline of the Embryology of the Eye. With illustrations from the original pen drawings by the author. By Ward A. Holden, A.M., M.D. The Cartwright prize essay for 1893. New York: G. P. Putnam's Sons.

In this little book is condensed a very lucid statement of the development of the eye, admirably illustrated by the author's drawings. It is an account of original research and full of interest. If any portion should be signalized as specially satisfactory, it is the description of the vitreous body. Less complete is the account of the retina, as would be expected from the inherent difficulty of the subject. Quotation or condensation cannot give a suitable account of the work, because only a careful perusal would satisfy one who takes an interest in the subject. The book is a worthy piece of original American work. Its get-up is very commendable.

The Health-Resorts of Europe. A Medical Guide to the Mineral Springs, Climatic, Mountain, and Seaside Health-Resorts; Milk, Whey, Grape, Earth, Mud, Land, and Air Cures of Europe. By Thomas Linn, M.D., with an introduction by Titus Munson Coan, M.D. New York: D. Appleton & Co. 1893.

The comprehensive title of this volume leads one to expect a rather complete work on European health resorts. As a matter of fact, the information given by the author is often so meagre as to be misleading. To write for medical men and the lay public at one and the same time is always difficult, and can in the nature of things be rarely satisfactory. The author's mastery of English is no more complete than his mastery of the subject matter with which he deals. As a fair specimen of the author's style, we quote the following description of Italian resorts (p. 270):

"They one and all lack in attractions such as the French are clever enough to provide for visitors. This may be owing to the Italian character, and the other defects may be owing to want of sanitary science; while the language is perhaps also a reason. In any case, none of these places are resorted to as much as those on the French coast; and just as soon as Alassio is past the climate is no longer suitable for winter residence. Genoa is not possible as a winter resort."

The medical directory appended to the volume is about as needless an infliction on physicians and lay readers as it is possible to contrive. If a second edition of the work should ever be called for, we advise that it be made fairly representative, or what would be much better, that it be altogether omitted.

Transactions of the Medical Association of Georgia for 1893.

A well-prepared volume containing thirty-seven papers on a wide variety of topics, besides matter of local interest.

Transactions of the Association of American Physicians. Eighth Session, held at Washington, D.C., 1893. Pp. 398. Philadelphia: Published by the Association. 1893.

This volume contains thirty papers, all of the highest value and attractively presented. Many of them have been published in the journals and have been carefully read by thousands. The present compilation is one which worthily represents the best scientific thought of American physicians, and will do much for their reputation among their foreign confrères. It is noteworthy that almost no space at all is required for the recording of merely executive business. All the time at the meetings seems to be devoted to scientific work. This example might well be followed by several medical bodies we might name.

A Manual of Practical Hygiene, Designed for Sanitary and Health Officers, Practitioners, and Students of Medicine. By W. M. L. Coplin, M.D., Adjunct Professor of Hygiene, Jefferson Medical College, and D. Bevan, M.D., Instructor in Hygiene in the same Institution. 140 Illustrations, partly in colors. Pp. 456. Philadelphia: P. Blakiston, Son & Co. 1893.

This work is perhaps the most satisfactory one we have yet had on the most important topic of hygiene. This satisfaction arises from its completeness, and from the condensation which has been practised in setting forth various details. "Prevention of Disease" is the implied text of every chapter, and the clearness of the authors will bring home hygienic truths to the mind of the non-medical man fully as forcibly as to that of the physician. Titles of chapters are: Individual Hygiene, Clothing, Food, Air, Water, Climate, Soil, Sewage, Habitations, and Disposal of the Dead. A section on technique is added, with full directions for laboratory work. While the volume contains very little essentially new, it is a commendable setting forth of a subject of paramount importance.

Mental Nursing. A Text-book for Asylum Attendants and Nurses. By William Harding, M.B. Pp. 131. London: The Scientific Press. 1893.

The object of this manual is implied in the sub-title. To the wording of the main title objection can, in a scholastic sense, be taken. Chapters treat of the outlines of anatomy, first aid to the injured, ventilation, and hygiene, etc., with special reference to the insane. We find much common sense in this work and unhesitatingly commend it.

A Theory of Development and Heredity. By Henry B. Orr, Ph.D., Professor at Tulane University of Louisiana. Pp. 255. New York: Macmillan & Co. 1893.

The scope of this work is well expressed in the author's preface, in the statement that he believes that, "by a critical review of the facts of biology in the light of the great conclusions derived from the allied sciences of physics and psychology, we may obtain a view of the great phenomena of life which shall bring into harmony a more extensive range of facts, and explain intelligibly relations which have hitherto been hidden." The facts are presented in an attractive manner, and the work is a valuable contribution to a most attractive and growing line of thought.

Seventy-fifth Anniversary of the Medical Society, District of Columbia.—In an address delivered at this anniversary by President Dr. Samuel C. Busey, he recalled the fact that the charter of the society was granted and approved by President Monroe, February 16, 1819. The Medical Society of the District of Columbia is the youngest of twelve medical societies in this country now in existence, which have reached and passed the seventy-fifth year of continuous active life, and is the oldest, if not the first, scientific body chartered by an act of the Congress of the United States. Ten of its founders were natives of Maryland, four of Virginia, two of Massachusetts, two were born within the present limits of the District of Columbia, and of three the nativities are unknown. In personal lineage it is confined to three of the original thirteen States, but as a scientific body it claims ancestral descent from eleven progenitors, who are present by representation. It is, however, the natural and direct heir of the Medical and Chirurgical Faculty of Maryland.

Society Reports.

LONDON CLINICAL SOCIETY.

Inhalation of Carbolic Acid in Phthisis.—Dr. Smith showed a case of phthisis which had recovered in eighteen months under the influence of change of climate and inhalations of carbolic acid. The inhaler used was an ordinary hat-box in which flannel charged with carbolic acid was suspended.

Dr. Davies showed a patient with myxœdema whom he had presented to the Society two years previously. Thyroid treatment, which had been persevered with since that time was beneficial, but whenever it had been discontinued a relapse occurred. The first indication of a relapse was an increase of weight.

ROYAL MEDICO-CHIRURGICAL SOCIETY (LONDON).

Pleurisy Caused by the Pneumococcus.—Dr. Washbourn described three cases in which all the symptoms indicated pneumonia, but the physical signs were not characteristic. On the tenth day the temperature dropped, the constitutional symptoms disappeared, but the physical signs did not disappear. After a few days the temperature went up and exploration of the chest revealed pus, which on examination was found to contain pneumococci. The pleural cavity was drained and the patient made a good recovery. In another case where the symptoms were of the same class as the first, but much more severe, the patient died after a few days' illness. The autopsy showed the lungs to be in a healthy condition, but the right pleural cavity contained fifty-four ounces of pus, in which were found pneumococci. In the third case, occurring in a child, there was double pleurisy with an effusion which, on being examined, showed pneumococci. Dr. Washbourn emphasized his belief that the pneumococcus might produce the same constitutional symptoms when invading the pleura as it did when invading the lungs. He believed that many cases diagnosed as pneumonia, but with equivocal signs, were really cases of pleurisy caused by the pneumococcus.

(This case is further discussed by our London correspondent on page 413.)

HARVEIAN SOCIETY (LONDON).

Tuberculous Iritis.—Mr. Silcock presented a phthisical patient, a boy twelve years of age, who had well-marked tuberculous iritis. Situated at the inner end of the horizontal diameter of the right cornea was a mass of vascularized exudation about the size of half a pea; this covered the anterior surface of the iris and filled up the corresponding part of the angle of the anterior chamber. There was slight ciliary injection and numerous posterior synechiæ.

PATHOLOGICAL SOCIETY (LONDON).

Rodent Ulcer.—Mr. Bowlby read a paper on rodent ulcer based on a study of sixty-six cases, and reached the following conclusions: 1. That rodent ulcer was more common in males than in females. 2. That it was not usually a disease of old age, but commenced most frequently between the ages of thirty and fifty, and might begin in youth. 3. That the growth might develop for several years before ulceration began. 4. That it very rarely occurred except on the face and adjacent parts. 5. That in the majority of cases where ulceration had commenced, the edges of the ulcer were raised and thickened, and there was good evidence of tumor growth, but that other cases did not differ structurally from others where the edges were flat and sharply cut. 6. That the cell masses and the cells themselves were distinguishable from those of other tumors, and possessed characteristics of their own. 7. That the epithelial nature of the cells and their enclosure in alveoli justified the inclusion of the growth among the carcinomata. 8. That there were good reasons for believing that the growth commenced in the derma, and that it might originate in the hair follicles

LONDON MEDICAL SOCIETY.

Treatment of Peritonitis.—Mr. Treeves, in speaking of the treatment of peritonitis in his third Lettsomian Lecture, said that absolute rest in the recumbent posture was the first indication. As little food as possible should be given by the mouth, rectal injections of peptonized meat extract being the best method of administering nourishment. As little opium as possible should be administered. Aperients can never be adopted as routine treatment. Blood letting may be advantageously employed in the robust forms of localized peritonitis. The operative treatment of purulent peritonitis, especially when the suppuration is localized, has been remarkably successful.

Administration of Anæsthetics Clinically Considered.—Mr. Joseph White related the results of forty years' experience in the administration of anæsthetics. He said that the effects produced by chloroform inhalation might, for practical purposes, be divided into four stages: The first a period of continued consciousness, the second a period of semi-unconsciousness, the third a period of sleep, and the fourth one of coma and threatened death. In most of the early cases of recorded death from chloroform, the patients died in the first stage. He said that he could not agree with the conclusions of the Hyderhabad Commission, that the only point of importance was to watch the respiration, for he held that the pulse was an equally valuable indication, and he watched both jealously. As a preliminary step, the patient should be encouraged as to the prospects of the operation. A few spoonfuls of liquid nourishment may be given three or four hours before the anæsthetic, but no solid food. The anæsthetist should give his undivided attention to the patient. The anæsthetic should be given gradually. When the patient struggles the inhaler should be removed. The operation should never be commenced till the stage of sleep was reached. If the eyeball became fixed and the respiration stertorous, the administration should be stopped. The patient should not be suddenly aroused, but fresh air and ammonia should be used as restoratives. If the pulse or respiration failed, an immediate recourse should be had to artificial respiration. He used the A. C. E. mixture almost exclusively, and found it to be less depressing and irritating, and freer from dangers, than chloroform alone.

MEDICAL SOCIETY OF THE HOSPITALS (PARIS).

Tuberculous Ascites Cured by Puncture Followed by an Injection of Camphor-Naphthol.—A year previously Dr. Rendu had presented to the society a patient cured of tuberculous ascites by puncture and the intraperitoneal injection of camphor napthol. He now presented an analogous case occurring in a girl seven years of age. The ascites had all the appearance of an essential ascites, and on puncture six quarts of a perfectly transparent fluid were withdrawn. Then about three and a half scruples of camphor-napthol was injected; this caused neither pain nor burning sensation. Recovery was quite complete in five weeks.

Hysterical Paroxysms in the Form of Facial Neuralgia.—Dr. Gilles de la Tourette said that hysteria might really be considered as a disease constituted by a collection of permanent stigmata, such as sensory and vasomotor troubles, contractures, amyosthenia, etc., which evolved in paroxysms. He related the case of a laborer fifty four years old, who, when he was thirty-eight years old, had an attack in which he lost consciousness, bit the tongue, and foamed, so that his attack resembled some-

what an epileptic; but was clearly an attack of what has been described as hysterical apoplexy.

After three weeks the patient, who was hemi-anæsthetic on the right side, was taken, without attributable cause, with a right side sciatica. Concurrently with the sciatica he developed right side tic douloureux. These attacks have become paroxysmal, and their cessation often coincides with the emission of a large amount of clear, light-colored urine. Other stigmata of hysteria, such as hysterogenous zones, are present.

Nature of Exophthalmic Goitre.—Dr. P. Marie said that the phenomena observed while applying the thyroid treatment for myxœdema, had led him to believe that the view advocated by Gauthier and Möbius, who state that the thyroid gland is the direct cause of Basedow's disease, is untenable. He said that, although some of the pathognomonic symptoms of Basedow's disease may be caused by a functional disturbance of the thyroid gland, he did not believe that the origin of the disease could be found in that gland. He based his conclusions on the fact, 1, that in no case of myxœdema in which the thyroid had been administered had exophthalmia or Von Graefe's symptom developed; 2, that the theory of the thyroid origin of Basedow's disease does not accord with our present knowledge concerning the etiology of the disease.

It is impossible to reconcile the sudden advent of the symptoms in Basedow's disease, such as frequently occur after fright, with any explanation other than causative factors arising through the intervention of the nervous system, particularly the sympathetic system. From this disorder of the nervous system results exaggerated activity of the thyroid gland, which in turn causes hyperthyroidation of the system, and as a consequence symptoms develop which are common to thyroid feeding and Basedow's disease.

Regarding treatment, the speaker is heartily in favor of the operative in preference to the medical. The results of thyroidectomy, he thinks, are indisputable; and likewise he is inclined to look with favor on the method known as esothyropexia recently described by Poncet.[1]

SURGICAL SOCIETY (PARIS).

Pregnancy Mistaken for a Cyst.—Dr. Monod related the case of a young woman, twenty-four years of age, who was operated on by Dr. Reverdin for an enormous cyst of the ovary. After the operation she recovered very quickly. Nineteen months later she again presented herself on account of a rapidly increasing enlargement of the abdomen. On examination there was a globular tumor reaching nearly to the umbilicus. The cervix was mobile and not altered. Fluctuation was easily obtained on palpation. It was supposed that a new cyst was forming, and an operation was decided on. The abdomen was opened, and old adhesions, the result of the previous operation, were broken up, the tumor was pulled forward, and was thought to be a cyst of the parovarium. A little incision was made into the tumor, which was followed by an escape of fluid and then a mass which was recognized as the umbilical cord. It was not until then that it was recognized that the tumor was a gravid uterus, and that it contained a four months' fœtus with its placenta. The adhesions, the result of the previous operation, had so displaced the uterus and compromised its nutrition that hysterectomy was decided on and done. The patient made an excellent recovery.

THERAPEUTIC SOCIETY (PARIS).

Digestibility of Cod-liver Oil.—Dr. Patein made a report on cod-liver oil. He said it was easily digestible on account of the biliary principles which it contained. It had important excitant and thermogenic properties, due to the phosphorus and the iodide which it contained in organic combination, and to the numerous alkaloids which have been isolated by different investigators. These alkaloids exist more abundantly in the pale oil, and are the result of auto digestion of the livers after three or four days of maceration. It is a process of auto digestion and not putrefaction, because the livers have during this time an acid reaction, whereas if putrefaction were going on, the reaction would be alkaline. In speaking of its therapeutic application he mentioned its value in pulmonary tuberculosis, rachismus, and as an external application in some dermatoses. Its value in rheumatism is doubtful. He advised its administration in small doses, and that it should be stopped altogether if it caused disturbance of the gastro intestinal tract.

Treatment of Pseudo-membranous Angina.—Dr. Piedalu said that in the treatment of that form of angina in which the false membrane contained the bacilli of Klebs-Lœffler he had obtained excellent results from a mixture of biniodide of mercury, 0 50; iodide of potassium, 30.00; simple syrup, 1,000.00. Administer in doses varying from one to two teaspoonfuls every two hours, according to the age of the patient. After several hours the signs of hydrargyrism manifest themselves, and it is then necessary to diminish the amount of the medicine. Two or three times a day he lifts the false membrane with forceps and gently detaches it. As a rule, recovery begins to set in in about forty eight hours.

Accidents with Chloralose.—Dr. Bardet said that chloralose produces an excito motor action on the spinal cord, which should inspire a certain reserve in its administration. Richet has recommended that the beginning dose be about 0.10 gm., and Landouzy has counselled beginning with 0.20 to 0.30 gm. In reality, however, it is often necessary to give not less than 0.50 to 0.60 gm. Poisonous symptoms have been noticed in two cases by Morel Lavalle and in one case by Talamon following the administration of the drug in 0.75 gm. dose. The writer has himself observed two cases of poisoning following the administration of the drug. In one case an old lady, after taking 0.75 gm., developed trembling of the arms and hands, great agitation, dyspnœa, and incoherent delirium. The second case, an infant, was given 20 ctgr., which at first produced sleep, but in two to three hours he began to grind the teeth, kick off the clothing, then had spasms, tetanic contractions, and trembling of the extremities. The speaker concluded that it had no advantages over sulfonal, and he gives his preference to the latter.

ACADEMY OF MEDICINE (PARIS).

Stomach and Cardiac Trouble Produced by the Habitual Posture of School Children.—Dr. Motais, of Angiers, pointed out that the habitual posture of school children is an important cause of myopia and of curvature of the spinal column. It is the cause of dyspepsia, because the bending forward causes constriction of the stomach. The faulty position impairs the current of blood through the vessels of the neck, and the result of this is cardiac palpitation. Most of the cardiac and stomach troubles of students and clerks he believes can be caused to disappear by correcting the faulty posture.

CHIRURGICAL SOCIETY (PARIS).

Trephining in Gun shot Wounds of the Cranium.—Dr. Quenu, in discussing this subject, said that he thought the surgeon should trephine in these accidents before the appearance of meningo-encephalitis. Septic manifestations may come on at any time from the presence of the ball or from foreign substances carried in with the ball, and it is contrary to the first principles of the antiseptic treatment of wounds not to remove the *materies morbi* and cleanse the wound. He is of the opinion that an early operation in perforating wounds of the skin is of great advantage in all cases except where the projectile has sunken to a considerable depth.

Dr. Despres said that he did not believe a surgical

[1] Medical Record, March 3d.

operation was indicated in fractures of the cranial bones where the bullet penetrates the substance of the brain.

Dr. Delorme said that from experiments and practical observation he was convinced that in perforating gun-shot wounds of the cranial bones, where the missile has projected to any depth, operation is not only useless but dangerous.

Dr. Monod thought that in perforating gun-shot wounds of the head a surgical operation when skilfully performed added nothing to the gravity of the patient's condition.

BERLIN MEDICAL SOCIETY.

Syphilis and Aneurism.—Dr. Fraenkel said that some writers have stated that syphilis can be traced as a preceding factor in the causation of aneurism in from sixty to eighty per cent. He found fifty per cent. of his cases suffering from aneurism to have had syphilis. He then demonstrated a specimen of arterio-sclerosis with syphilis of the heart. The patient had had aortic insufficiency, severe headaches, and attacks of vertigo. He also showed a second specimen of aneurism with perforations into the œsophagus.

Vaginal Laparotomy.—Dr. Duhrssess exhibited several photographs illustrating his new method of vaginal laparotomy. The method comprises: 1, opening the anterior wall of the vagina; 2, section of the plica vesica uterina; 3, extraction of the uterus with its adnexas, with vertical incision of the anterior vaginal wall until they are visible in the vulva and can be operated on. He considers the procedure especially indicated in cases of retroflexion and small myomata.

SOCIETY FOR PSYCHIATRY AND NEUROLOGY (VIENNA).

Peculiar Form of Bulbar Paralysis.—Dr. Pineles showed a woman, twenty-five years old, who presented peculiar symptoms of complex bulbar paralysis. The disease began suddenly, without apparent cause, in January, 1892. The first symptoms were headache, dizziness, diplopia, and right-sided ptosis. After a few weeks' duration of these symptoms there was a remission of symptoms for one year. In July, 1893, she had an attack accompanied with difficulty in swallowing and chewing, thick and unintelligible speech, palpitation, great weakness of arms and legs, and, finally, attacks of smothering. All these symptoms developed within a week. There was a remarkable exacerbation of symptoms in the evening and remission in the morning. The patient has recently so far recovered that there is now only a slight nasal twang to the voice, slight ptosis of right lid, and slight paresis of the mouth. The patient has no psychical or sensorial defect. The electrical reactions are normal, and there is no muscular atrophy. The patellar and palate reflex are preserved. The speaker said he had observed two similar cases of respectively one and one-half and two years' duration, which, without any severe symptoms preceding, died suddenly in an attack of dyspnœa. He thinks these cases can be entirely differentiated from other bulbar affections, such as progressive bulbar paralysis, apoplectiform bulbar paralysis, pseudo-bulbar palsy, tumor in the medulla, etc. He said that in similar cases where autopsy has been made no lesion could be demonstrated to account for the symptoms.

MEDICAL CLUB (VIENNA).

Thrombosis of the Portal Vein and Acute Yellow Atrophy of the Liver.—Dr. Foges related the case of a man, twenty five years of age, who a few weeks previously developed an œdema beginning over the lower part of the sternum and gradually involving the scrotum, the lower extremities, and the hands. Associated with this development were severe pain in the back and epigastrium, bloody expectoration, jaundice, dyspnœa, and finally collapse. The autopsy revealed chronic interstitial nephritis, cardiac hypertrophy, and chronic myocarditis, infarction of the lungs, spleen, and supra-renal capsules, thrombosis of the portal vein, and acute yellow and red atrophy of the liver. Dr. Foges thought the kidneys and heart were the starting-point of the other manifestations.

CONGRESS OF RUSSIAN PHYSICIANS.

The Use of Pilocarpin in Disease of the Middle Ear and Labyrinth.—Dr. Jirmunski said that his experience with the use of pilocarpin in acute disease of the middle ear and labyrinth had been a satisfactory one. In old cases it was quite useless, both when used subcutaneously and by direct instillation. He related two cases of deafness due to acute disease of the labyrinth, which were rapidly cured by the use of pilocarpin. The first case was a young man, aged nineteen, who fell down some steps, was unconscious for upward of two hours, and had quite an extensive hemorrhage from the left ear. Thirteen days after there was found complete deafness to both bone and air conduction in the left ear. The diagnosis was traumatic labyrinthitis with hemorrhage. Pilocarpin 0.004 gm. dose was injected subcutaneously, and this amount increased daily one milligram till 0.02 gm. was reached. At the same time, every second day, four to ten drops of a two per cent. solution of iodide of potassium was dropped in the ear. After the fifth injection, hearing in the left ear began to be present, and after nineteen injections hearing was quite restored.

The second case was one of syphilitic labyrinthitis with sudden advent of deafness, which was handled in a similar manner. After twenty-four injections the patient's hearing was entirely restored.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, February 12, 1894.

Charles A. Powers, M.D., Chairman.

Chronic Unilateral Œdema of the Lower Extremity.—Dr. Robert Abbe presented a young woman who had, according to his experience, a rather rare condition, namely, chronic œdema or hypertrophy of the right leg, of four years' standing, slowly increasing, the left leg being normal. It was not like an ordinary œdema, there was no pitting on pressure, there were no varicose veins; no apparent cause. The enlargement was chiefly below the knee, scarcely at all of the upper thigh. There had been no improvement under the elastic bandage or other treatment until electricity was used twice a day, beginning a month ago, since when there had been considerable diminution in size. It was probably a lymphatic disturbance.

Dr. Abbe showed the photograph of another case, under Dr. Weir's care a year and a half, during which time there had been considerable increase in the right leg, commencing in the thigh and extending down. In neither of these cases had there been a history of appendicitis, although this, by giving rise to pressure, had been considered the cause in certain cases on record. Unilateral œdema also affected the left leg occasionally. Dr. Abbe could recall one other case which he had seen.

Dr. Reginald H. Sayre presented drawings of a case found in his father's record books to which his attention had been called by Dr. Yale. The patient was a girl of fourteen years, was seen in 1871, had had increasing enlargement of the right leg since 1868. Dr. Sayre applied pressure, and after a few months the limb was reduced to its normal size. Dr. Reginald Sayre thought failure with pressure treatment might have been due sometimes to want of proper application of it.

Neuropathic Inflammation of the Shoulder joint.—Dr. Willy Meyer presented the patient, a man, thirty-

seven years of age, well nourished, who was first seen by him two months ago, when he complained of inability to use the left arm properly, and also showed a recent swelling in the region of the left breast. The head of the humerus was dislocated into the axilla. The history was that last summer, when the man wished to lie down on the floor, something gave way as he placed his weight upon the left arm. He felt no pain then and had felt none since. Crepitation was distinct. The arm could be moved freely. The swelling in the left chest was evidently due to synovial fluid which had escaped from the ruptured synovial sac. The diagnosis lay between a neuropathic inflammation secondary to tabes or to syringo-myelia, as there were no symptoms of tabes this was excluded. Dr. G. W. Jacoby confirmed the diagnosis of syringomyelia.

Tabes and Neuropathic Inflammation of the Finger-joint.—Dr. Meyer also presented a man whom he had been requested to see in consultation. He had struck a boy and immediately afterward the left index-finger was found to be swollen. After twelve days he saw a physician, who diagnosed fracture at the base of the finger and put on a splint. Dr. Meyer noticed at once that the man's walk was peculiar, found the knee-jerk gone, inability to stand with the eyes closed, and other evidence of tabes, secondary to which was neuropathic inflammation of the index finger. There was a history of syphilis.

In discussing Dr. Abbe's case, Dr. Bryant said he had seen a similar one.

Dr. Kammerer had also seen one and had amputated the enormously enlarged leg as it interfered with getting about. The condition had lasted fifteen years.

Dr. R. H. Sayre had seen a case of swelling of the foot and ankle in a man supposed to have tabes, the swelling was supposed to be neuropathic inflammation, but it disappeared under pressure and quiet. He thought the destruction of the joint in similar cases would not progress so rapidly if protection were given.

Further Observations on Relapsing Appendicitis.—Dr. William T. Bull read the paper (see p. 385).

Dr. Robert Abbe thought it must be apparent to all that a great many persons who had been regarded as hopeless invalids in the past were, by operations upon the appendix, being put upon their feet and restored to their usefulness in the community. The most persistent and annoying symptoms present before the operation disappeared after it, notably dyspeptic symptoms. He mentioned the case of a man who had been a chronic invalid, scarcely able to eat anything, who after removal of the appendix began to eat ravenously. The low grade of inflammation, irritation, and inflammatory adhesions about the appendix had been the cause of the chronic invalidism. If the clinical features were at all strikingly those of appendicitis and there was a previous history an operation should be done at once.

Dr. Bryant had been somewhat surprised at the number of cases in which the secondary operation had been performed, and at the low mortality attending it. Was it possible that experience in this class of cases would come to be so favorable as to lead the profession to the unscientific position of advising removal of all appendices?

Dr. Kammerer said his experience with relapsing appendicitis had led him to advocate the operation whenever there had been two or three relapses.

Dr. Willy Meyer related a case which showed the value of palpation in diagnosis of diseased states of the appendix, and also of operation between attacks, since the abscess found in this case pointed to the danger of procrastination.

The Patient's Story not the best Guide to Operation.—Dr. G. M. Edebohls thought the time had come when, like in other diseases, we were not to depend for guidance in operating upon what the patient could tell us, but upon physical examination.

In acute appendicitis one could feel within twenty-four hours some tumor which, with the symptoms, gave indication for an operation; in some cases there would be a large mass, in others only a thickened, sensitive appendix. Chronic appendicitis, with more or less acute exacerbations, also gave rise to pathological changes which were recognizable by touch. There were some cases, also, in which, after removal of the appendix, no changes were apparent in it, yet the patients were free thereafter from further trouble. Dr. Edebohls then described his method of palpating the appendix, whether healthy or diseased.

Acute Attack Set up by Palpating the Appendix.—Dr. R. T. Morris referred to one case in which he had palpated the appendix, an acute attack of inflammation followed, but fortunately he was able to save the man's life by an operation. Palpation, therefore, was not without some danger. He believed in operating between attacks, and had removed the appendix in some very mild cases where operation had been refused by some most enthusiastic surgeons. A chronic inflammation of the appendix, although of mild grade, might, through long-continued irritation, have grafted upon it carcinoma, or other form of inflammation. He had seen several cases of tuberculosis which developed after appendicitis had lasted some time. He combated the long incision, recommending the inch and a half one, without gauze packing, or drainage-tube; lamp-wick was better, as it was small and caused no pressure.

Dr. Bull closed the discussion. He thought we were indebted to Dr. Edebohls for perfecting the method of palpation. He had failed to feel the appendix so distinctly as Dr. Edebohls had done, and thought the latter might find it less easy in males than in females, since in the former the abdominal muscles were apt to be more rigid. Regarding gauze packing, he had also felt that some of his colleagues used it in excess; that quite as good capillary traction could be secured by a small amount, and if it were properly sterilized the simple gauze was preferable to the iodoformized.

Sarcoma of the Tongue—Dr. Bryant presented some specimens. The first was a round-celled sarcoma of the anterior third of the right side of the tongue, which had followed irritation by a rough tooth. The condition had existed over six months when he saw the patient, and at that time the tumor was round, smooth, hard, sessile. He removed it, with some healthy tissue, under cocaine anæsthesia. Dr. Dunham examined the specimen microscopically. Record was found of only fourteen cases of sarcoma of the tongue. Lipoma was about equally rare.

Sarcoma Developed on Adeno-fibroma.—Dr. Bryant's second specimens consisted of the right and left breasts of a maiden lady, of forty-nine years of age, who had noticed a tumor in each breast since she was sixteen, but which had remained quiescent until three years ago, when that in the right breast began to undergo change which microscopical examination showed to be sarcomatous. Doubtless the original tumor in this breast was, like that in the left breast, adeno-fibroma. The case showed the importance of early removal of tumors, and the relation between sarcomatous growths and adenoid growths.

The third case was one of fibro-sarcoma of the left breast. The right breast also contained some enlargements, which the patient would allow to be removed should they begin to grow.

Dr. Abbe said he had removed a sarcoma of the tongue eight or nine years ago. There had been no recurrence.

Dr. Dowd referred to a paper read by him, in which he described some cases of change from simple to malignant tumors.

Dr. J. P. Tuttle saw a patient, not long ago, who had a tumor of the rectum, pronounced by Dr. Beach, after microscopical examination of part of it, to be adenoma. Three weeks ago Dr. Tuttle operated, removed the tumor, and found distinct evidence of sarcoma, not carcinoma.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 13, 1893.

H. P. LOOMIS, M.D., PRESIDENT, IN THE CHAIR.

Endothelioma of the Tonsil.—DR. WARREN COLEMAN presented, through the kindness of Dr. Asch, a specimen of endothelioma of the tonsil. Dr. Asch presented it before the Laryngological Section of the Academy of Medicine on November 22d. The patient, a lady, thirty-five years of age, consulted Dr. Asch on October 12th, because her dentist had told her on the preceding day that there was something wrong with her throat. She said that when the same dentist saw her two weeks before, there was nothing abnormal visible in the throat. Examination revealed a tumor of the right tonsil, completely filling the right half arch. It extended to the vomer in the middle line, and downward below the base of the tongue. It was flattened on the anterior surface, slightly nodular, red, and bleeding easily when touched. At one point it reached to the anterior pillar. There was no pain whatever, no interference with respiration or deglutition, and the patient had been up to this time absolutely unconscious of its presence. On the same side was an enlarged submaxillary gland, which was said to have been there since childhood. The growth was removed on October 14th, with Knight's galvanic tonsillotome. On October 26th, a small outgrowth from the tonsil was noticed, which increased until November 15th, when it projected beyond the pillars internally, and well down the pharynx posteriorly. This was removed by a second operation.

The tumor after hardening measured 2.85 ctm. in its antero-posterior diameter, 1.58 ctm. in its vertical diameter, 6.35 mm. through the centre, and 9.5 mm. in its thickest portion. The free surface was irregular, and presented nodular elevations at different points. None of these nodules were large. Its attached portion was rough and ragged. Under a low power of the microscope a vertical transverse section through the entire specimen showed the proper substance of the tonsil to be replaced by a tissue consisting of cells larger than lymph-cells, and which contained a large number of blood-vessels. The remains of the tonsillar structure could be seen in places under the mucous membrane in the form of lymph nodules. The new tissue occupied almost the whole gland. In many parts of the section, the cells were arranged in distinct groups, which were only incompletely marked off from each other by small bands of connective tissue containing blood-vessels. The vessels were more numerous than in a normal gland, and were in intimate relation with the cells. Unfortunately the tissue was immersed too long in weak alcohol, and, as a result, the protoplasm of the cells was largely broken down into granular detritus, but those which retained their protoplasm were seen to be irregularly oval and of large size. The cells were distinctly of the flat variety, and both cells and nuclei varied in size; the latter generally showed karyo-kinetic figures, thus giving evidence of rapid subdivision. The section was stained particularly with a view to bringing out any fibres that might penetrate between the individual cells, but in no part of it could they be demonstrated.

The stratified epithelium covering the free surface of the tonsil showed signs of irritation in the vacuolation of the cells of the superficial layers, and the presence of small round cells infiltrating the lower layers.[1] These latter were quite marked, and in places had extended far up into the epithelium.

The recurring portion of the growth presented essentially the same appearance, except that the cells were as a rule somewhat smaller. The section was almost completely surrounded by stratified epithelium, and under this a relatively large amount of lymphatic tissue remained. At the junction of the neoplasm with the lymphatic tissue, fibres could be seen between the cells, but they appeared to be the remains of the retiform tissue, disappearing as one passed into the substance of the neoplasm.

The malignancy of the growth was recognized immediately on examining the section, but its real nature was not apparent without close study. It had to be differentiated from carcinoma on the one hand, and from alveolar and lympho sarcoma on the other. The size, shape, and characters of the cells, and their intimate relation with the blood vessels, distinguished it from carcinoma. It could not be an alveolar sarcoma because the small amount of connective tissue which marked off the cell-groups did not send in prolongations between the individual cells, and because of the variety to which the cells belonged. Nor was it lympho sarcoma, though it had its origin in a lymphatic gland, because of the absence of retiform tissue. The cells were held together by cement substance, the most careful examination having failed to demonstrate fibres between them.

Dr. Coleman said that the literature contained only a very limited number of reports of endotheliomata occurring in any part of the body, and not one in this region. According to the "American Text-book of Surgery" (page 200), when endotheliomata "arise in the pia mater, structurally and from their mode of origin many of them are alveolar sarcomata, while those originating in the pleura or peritoneum are carcinomatous, consisting of nests and clusters of epithelial cells presenting at their periphery a columnar appearance, these cells being surrounded by a dense fibrous stroma." In Delafield and Prudden's book, it is stated that the cells making up an endothelioma may vary from the flat to the spherical variety. In the latter case it seemed to him that a diagnosis would be particularly difficult. Were it not for the special characters of the cells in this tumor of the tonsil, he would unhesitatingly class it as an alveolar sarcoma, despite the absence of fibres between the cells. As before mentioned, the intimate relation of the blood-vessels to the cells excluded carcinoma.

Infantile Cerebral Spastic Diplegia.—DR. FREDERICK PETERSON presented the fresh brain of a case of infantile cerebral spastic diplegia. The case was that of a female infant, aged twenty months, which had congenital diplegia, that is, spastic paralysis of all four extremities. He had frequently observed the child during his rounds at the Randall's Island institutions. It was subject to convulsions, had enormously exaggerated knee jerks, ankle clonus, and the like, and its head was exceedingly small. The head measurements were: circumference, 32.5 ctm.; antero-posterior diameter, 11.5; greatest transverse diameter, 9.5 ctm.; naso-occipital arc, 18; binauricular arc, 19. At the autopsy the skull bones were found to be considerably thickened, and all the sutures and fontanelles closed and united. The dura was very thick. There was an increased amount of subdural fluid. Over each hemisphere, as shown in the specimen, a large group of convolutions, including especially the motor area, was found wanting. The vacuum caused by this atrophy was filled partly by subdural fluid, and partly by the bulging of each ventricle, for there was also internal hydrocephalus. There was no communication between the ventricles and the exterior of the hemisphere, and the roofs were formed by a membranous sclerotic tissue. On microscopic examination of the spinal cord, degeneration and atrophy were found in the lateral columns. The condition seemed undoubtedly to be due to a double meningeal hemorrhage, of which there was now no trace except the atrophied convolutions on both sides.

Chronic Hydrocephalus without a Cerebrum.—DR. PETERSON then presented the skull and brain of a remarkable case of chronic hydrocephalus without a cerebrum. The case was one of a female infant of eighteen months. Little could be learned of its early history. It had a large head with widely gaping fontanelles. The circumference of the head was 51.5 ctm.; antero-posterior diameter, 18; greatest transverse diameter, 15; naso-

[1] D'Arcy Power: British Medical Journal, October 14, 1893.

occipital arc, 32; binauricular arc, 34. The child was blind, and had nystagmus. There was rigidity of all four extremities, occasional convulsions, and toward the last, opisthotonos. The child often cried out at night. It rested easier on either side than on the back. Speaking to or moving the child caused it to cry out. The circulation was poor; the pulse rapid and feeble. The lungs were normal. The urine contained a slight trace of albumin; there was no trouble with the bladder or rectal sphincters. The child could not nurse and was fed with a dropper. It died suddenly in a convulsion. The temperature never rose above 98° F. during its month's stay in the Infants' Hospital. Toward the last it vomited occasionally after feeding. At the autopsy sixty-four ounces of reddish serum were first removed by tapping through the anterior fontanelle. The skull was exceedingly thin; the dura was thin; the falx cerebri had disappeared: at the base of the brain the basal ganglia stood out prominently, and the floors of the lateral ventricles were widely open. On removing the tentorium, the cerebrum was found to be of about the normal size. There was a mere vestige of each hemisphere, in a small part, some three inches long, at the base of each occipital lobe, lying on the floor of the skull. Microscopical examination showed degeneration and atrophy of the lateral columns of the cord.

Dr. S. T. Armstrong said that the condition of the basal ganglia and of the remaining lobes of the brain suggested that this might have been a partial anencephalic monster rather than a case of hydrocephalus with absorption of so large a part of the brain, for such extensive absorption seemed almost incredible.

Dr. Peterson said that he had seen an illustration of another case of hydrocephalus in which there had been almost as much wasting as in the specimen just presented. The fact that it was not a lack of development was proven by an examination of the spinal cord, which showed descending degeneration of the pyramidal tracts. If the case had been one of arrest of development, one would probably not find any trace of the pyramidal tracts.

Dr. Armstrong asked if this would not be a violation of the law that lesions of the cortex could have no effect on producing lesions of the peripheral nerves; in other words, were it not a fact that the evolution of the pyramidal tract was independent of the cortex.

Dr. Peterson replied that any lesion of any part of the fibres would result in degeneration.

Dr. Coleman said he had seen quite often a condition similar to that shown in the specimen, in dogs, monkeys, and pigeons where a portion of the brain had been purposely injured or removed in experiments. Almost an entire cerebral hemisphere had been absorbed in these instances, leaving only a large sac filled with fluid.

Dr. Peterson said that the most remarkable feature connected with this case was that the child was reported to have had convulsions. If this were true, it was very remarkable, because it was now believed that convulsions do not occur except from some cortical disturbance.

Extensive Cystoid Degeneration in the Adult Kidney.—The President presented two kidneys showing extensive cystic degeneration, occurring in the adult. Although this condition was quite common in children, in his experience it was rare in adult life. The patient was forty-three years of age, and was admitted to the alcoholic wards of Bellevue Hospital, suffering from acute alcoholism. He improved for a few days, and then became so lethargic that he was aroused with difficulty. He gradually grew weaker, and finally became comatose, and died in this condition on the twentieth day after admission. Only a chemical examination of the urine was made, but this showed a small quantity of albumin, and a specific gravity of 1.014. The autopsy was made thirty-two hours after death. Physical development was excellent; the brain, heart, lungs, and spleen were normal; the liver was slightly enlarged and fatty. Both kidneys were enlarged, and weighed nine ounces each. The whole surface of both kidneys was studded with small cysts varying in size from a pea to a cherry. Similar cysts were found throughout the substance of the organ. Microscopical examination of the fluid contents of the cysts showed crystals of uric acid, blood corpuscles, granular matter, and some acicular crystals of undetermined composition. The cysts were lined with flat cells. The kidney structure between the cysts showed quite extensive chronic parenchymatous nephritis; hence, the condition of the kidneys, in the absence of other causes, must be looked upon as responsible for the death.

The speaker was of the opinion that adults with cystic kidneys usually died of intercurrent renal disease, the symptoms ordinarily being those of Bright's disease. He was not aware that the condition had ever been diagnosticated during life. Two explanations had been given for this pathological condition: One, that it was an excessive development of the small microscopical cysts seen in the cirrhotic kidney; the other, offered by Virchow, that these cysts represent the low degree of the fœtal cystic kidney.

The speaker said that cysts of the kidney were divided into: 1, Fœtal cystic kidneys; 2, kidneys containing one or two cysts, and having no pathological significance; 3, the cysts found in the small cirrhotic kidney; and 4, extensive cystic degeneration in the adult.

Abscess of the Liver.—Dr. E. K. Dunham presented some specimens for Dr. McAlpin. The first were from a man, twenty-three years of age, of rather intemperate habits, whose last illness extended from October 9th to December 4th. Physical examination showed consolidation of the lung with some exudation into the right pleural cavity, which was diagnosticated as empyema. About half a pint of purulent matter was withdrawn by the aspirator. The patient died a few days later. At the autopsy, it was found that the liver was the seat of two or three large abscess cavities. The upper surface was adherent to the lower surface of the diaphragm, and there were adhesions between the upper surface of the diaphragm and the right lung. The lung appeared to be the seat of a lobular pneumonia, and it appeared also as though the aspirating needle had penetrated the liver, and that the pus was withdrawn from here. Bacteriological examination of the pus taken from the liver at autopsy revealed the presence of a variety of microorganisms, chiefly the colon bacillus and the streptococcus.

Amœboid Dysentery.—The other specimens were taken from a patient who was ill only about four days. The temperature was 104° F., the pulse and respiration rapid, and these were associated with abdominal pains and bloody stools. The case was treated for typhoid fever. At the autopsy the colon was found to be the seat of dysenteric ulceration; the liver contained a number of abscess cavities, and the pus in these was rather thick. Bacteriological examination of the pus from an unopened abscess failed to reveal micro organisms, but microscopical examination of the colon showed bodies of proper dimensions, and containing vacuoles and indistinct nucleus, thus corresponding in appearance to the amœba coli. The amount of suppuration was quite remarkable considering the short duration of the disease.

Dr. Armstrong remarked that studies at the Johns Hopkins University would lead us to believe that amœboid abscesses of the liver from the transmigration of the amœba coli, were more frequent than was usually supposed.

The Society then went into executive session.

The Souls of Animals.—Canon Wilberforce, in a recent interview published in the *Westminster Gazette*, contends that the lower animals are immortal, and uses his belief as an argument against the establishment of a Pasteur Institute in England. For all that, he doubtless takes his roast beef with as much satisfaction as if it had not been necessary to set free an immortal soul in order to procure it for his table.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

ANNUAL MEETINGS OF SOCIETIES—OBITUARIES—INFANTILE PARALYSIS—TUBERCULAR MENINGITIS HEALED BY DRAINAGE—THE PNEUMOCOCCUS—MYXŒDEMA—CARBOLIC INHALATIONS—DIPHTHERITIC PARALYSIS—DROWNED IN TEA—THE IRISH CORPORATIONS—DR. HUGHLINGS JACKSON—THE ROYAL SOCIETY'S CROONIAN LECTURE—PROFESSOR RAMÓN Y CAJAL IN ENGLAND—SIR W. BROADBENT'S RECOVERY FROM INFLUENZA.

LONDON, March 10, 1894.

THERE are already foreshadowings of the close of the session. Two of our societies have held their annual meetings, and although these functions do not conclude the work of the year they mark the approach of the end. In both cases the formal business and the election of officers for the ensuing year were completed as usual. At the Medico-Chirurgical, Dr. Church, Vice President, delivered the annual address, which he naturally opened with a reference to the death of the President (Sir Andrew Clark) and a correction of some erroneous statements about him. Brief mention was also made of other deceased fellows of the Society, but the Vice President doubted the utility of the old custom of commemorating every fellow who had died during the year, and thought that the journals usually gave all necessary particulars. This innovation does not, however, commend itself to all the fellows, some considering that an obituary notice in the address affords an opportunity of commemorating the best qualities of colleagues and stimulating survivors to emulate their virtues. The other annual meeting was that of the Medical Society of London, held on the 5th inst. The report of the council shows that the average attendance at the meetings has increased, that the clinical evenings continue to be very popular, and that the financial condition of the society is satisfactory. There are seven hundred and sixty fellows of this society. At the ordinary meeting which immediately followed the annual one, a paper was read by Dr. Lewis Jones on the electrical treatment of infantile paralysis. He held that good could be done to cases of not more than three years' duration if the children were young. He repudiated the notion that if the ganglion-cells in the cord were destroyed, recovery must be impossible, for some cells might escape, and it has been shown that the nuclei of origin of muscles may occupy considerable extent vertically. He thought the form of electricity applied of secondary importance—the great thing being that it must be prolonged—in fact it had to be continued for months or even years, and must therefore be intrusted to unskilled persons. This was a reason for employing electric baths. Massage and gymnastics were useful but inferior.

A case was then communicated which had been diagnosed as tubercular meningitis and which had recovered after treatment by drainage of the subarachnoid space. Cases in which drainage had been tried were mentioned by several speakers, and it was suggested that there would be better chances of success if the operation were not delayed until after coma had set in.

The pneumococcus took up a good deal of the attention of the Medico-Chirurgical Society on the 27th ult., *apropos* of some cases of pleurisy related by Dr. Washbourn. The constitutional symptoms pointed to pneumonia, but the sputum was not rusty, and the physical signs were not characteristic. The autopsy of the fatal cases discovered pus in the chest, and in the non fatal cases in which the diagnosis was made out and the chest explored, pus was found. In both the pus contained the pneumococcus. I suppose no one doubts that in most cases of pneumonia the coccus is present, but there are certainly some cases in which it cannot be detected, even by skilled bacteriologists. Again, it is found in other cases, *e.g.*, Dr. Kanthack said he had met with it in the pus of purulent meningitis, ulcerative endocarditis, peritonitis, pericarditis, otitis, and empyema of the frontal sinus. A further and more closely associated case is that of simple empyema in typical cases, of which I believe I am correct in saying the pneumococcus has been found in the pus. Are we then to revise our notions of the part played by this parasite, or to seek some other explanation of the facts? One course of variation is probably due to the stage at which investigation is made, for animals injected with the sputum before the crisis has occurred die of pneumococcus septicæmia, but if the sputum after the crisis be employed, they are rendered immune. Such facts suggest that the pneumococcus may, perhaps, set up a general disease of which pneumonia is the most common accompaniment, but which may manifest itself in the pleura, pericardium, or other serous membrane instead of the lung. In these cases some of the symptoms of pneumonia will be present, and this especially if the pleura is affected. Most physicians can recall cases in which they felt some doubt, and some have spoken of equivocal pneumonia. In pleuritic cases the temperature does not fall so rapidly, and after it has declined there is a second rise. When this is the case, if careful auscultation and percussion leave doubts it may be well to resort to the exploring needles, and if pus be found it can be examined bacteriologically. But even if found, we must remember that the pneumococcus has been met with in simple empyema. There is consequently abundant scope for further investigations. It was, of course, suggested at the meeting that influenza may have something to do with the cases in question. Neurasthenia then invaded the meeting in reference to its relationship to disorders of digestion. One member proposed to substitute the term "encephalasthenia" considering the exclusive seat of the troubles to be the brain.

There were some interesting cases exhibited at the Clinical Society on the 23d ult. Among them was a patient of Dr. Arthur Davies, formerly exhibited February, 1892—a case of myxœdema treated by thyroid gland. A relapse occurs whenever the treatment is discontinued. There was also a case said to have recovered from phthisis, under the use of carbolic-acid inhalations from a large inhaler made out of a hat-box, with flannel charged with the medicament suspended in it. The man, aged twenty-five, had used this for eighteen months.

A case of diphtherial paralysis was related by Dr. White, which proved suddenly fatal when the patient was drinking a cup of tea. He began to cough while drinking, extreme dyspnœa ensued, and he was dead within ten minutes. At the autopsy an ounce and a half of tea in the bronchial tubes was the only thing found to account for the death. How much more might have passed the glottis? Dr. White attributed the result to spasm set up by the liquid. Sensational newspapers have missed an opportunity. Drowned in a cup of tea would have been a fetching head-line. It was remarked by subsequent speakers that diphtherial paralysis is a peripheral neuritis, or rather a nerve degeneration—a point made clear by Dr. Sidney Martin's researches, and that it is caused by the diphtheria toxine. Cases of choking by solids were mentioned, but no one else had met with this effect of liquids. The practical remark was made that nasal feeding should be employed whenever there is dysphagia.

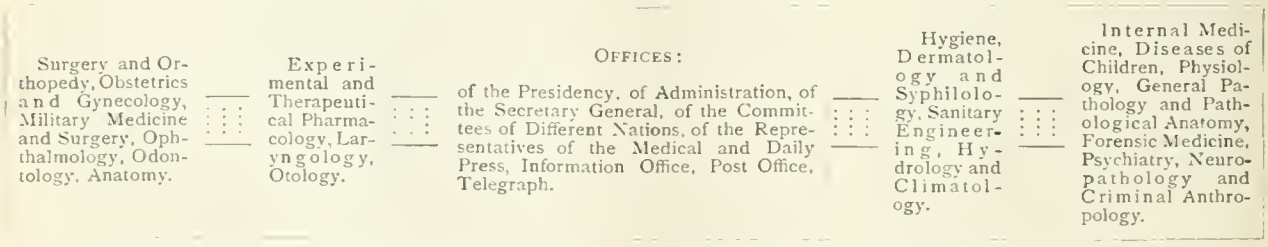
The Irish corporations seem on the verge of a truly national dispute. The general medical council is not satisfied with the curriculum of the conjoint board of the College of Surgeons and Apothecaries Society. The College of Physicians is accused of stirring up the mud in its own interest. The "loaves and fishes" again! That is usually the case with all our medical corporations. The vested interests of these bodies make up a formidable incubus for the profession to carry. No doubt in this case the "very pretty quarrel" will be made up, each of the parties preserving inalienable rights to qualify at a price as to which the student has no vote.

Dr. Hughlings Jackson's time of service at the London

Hospital has expired, and he has been appointed consulting physician. Twenty years is the term which may be held as full physician or surgeon at this hospital. Dr. Jackson had been eleven years assistant physician before his promotion occurred, so he has served the hospital for thirty one years, and well has he served it, too, as he has also served clinical and scientific medicine.

Professor Ramón y Cajal, of Madrid, has been here this week, and the University of Cambridge has conferred on him an honorary doctorship of science. On Thursday he delivered the Croonian Lecture before the Royal Society, in which he gave an outline of the results of his researches during the last five years into the structures of the nervous centres. The subject required close attention, as the learned lecturer spoke in French, which rendered it more difficult for an English audience to follow him; for a good colloquial knowledge of a foreign language, even with much reading, scarcely gives practice enough to enable an auditor to appreciate fully the fine points of a rather abstruse lecture.

Sir W. Broadbent, who has had influenza, is recovering, and expects to be able shortly to go out of town for change.



LETTER FROM ROME.

(From our Special Coespondent.)

THE OFFICE OF THE SECRETARY GENERAL OF THE CONGRESS—THE GENERAL SESSIONS AND THE SECTION MEETINGS—THE POLICLINIC—PROFESSOR BACCELLI—ARCHÆOLOGICAL INVESTIGATIONS — EDUCATION IN ITALY — PROFESSOR PAGLIANI—THE BUREAU OF PUBLIC HEALTH —VANDALISM IN ROME—PREPARING FOR A CROWD.

ROME, March 10, 1894.

THE office of the Secretary-General of the Congress was removed on March 2d from Genoa to Rome. On the same day the office of registration was opened in the Eldorado, in the Via Genova. The general sessions of the Congress will be held in the same building, a not very large wooden structure known as the Eldorado amphitheatre. There is little that is attractive in its present appearance, but doubtless the bare walls will be made less ugly by the decorations with which the committee has in mind to embellish them. The chief objection to the building is the small size of the auditorium, which does not look as if it could possibly accommodate the crowd that is always present in the first two or three public sessions. There will be five of these general sessions, at which twelve addresses will be delivered, in addition to the opening and closing meetings of the Congress. The nineteen sections will hold their meetings each day of the Congress, except the first and last, from eight to three o'clock, in the pavilion of the new Policlinic, outside of the walls of the city, near the Porta Pia. The buildings which will be occupied by the administration and sections of the Congress are placed as follows:

The Policlinic is a large building devoid of any architectural merit, but excellently adapted to the purpose for which it is intended, and also to its temporary use as a home for the sections. Each section will have a large hall for its meetings, and also smaller rooms for the use of the president and secretaries, and for the storage of instruments, pathological specimens, microscopes, and other scientific apparatus. The structure is not yet entirely completed, but it will be ready in ample time for the opening of the Congress.

Professor Baccelli, the President of the Congress, is an accomplished Latin scholar and archæologist, as well as a learned physician. Much of the excavation and identification of the ruins of the Forum and elsewhere has been carried out through his incentive. He is also Minister of Public Instruction under the present government, and the cause of primary education in Italy finds in him a zealous advocate. Professor Pagliani, the Treasurer of the Congress, is the Director General of Public Health at Rome. The International Exhibition of Medicine and Hygiene, to be held during the Congress week in the new and handsome Palace of Fine Arts, in the Via Nazionale, is a special object of his solicitude, and he has assumed the chairmanship of the special committee having this exposition in charge. The Exhibition will be opened on March 28th, the day preceding the inaugural session of the Congress, and on that evening the committee will give a reception to the members of the Congress and their wives, in the Fine Arts Palace. The Bureau of Public Health, under the able administration of Dr. Pagliani, has done, and is still doing, much to better the sanitary condition of the poorer quarters of Rome.

These works and those of the archæologists are, no doubt, useful and in accordance with the spirit of the times, but they are fatal to the beauty of Rome. Wide and well paved streets, and new, light, and well-ventilated buildings are demanded by hygienists, and physicians, of all others, should not complain of them—but they are not picturesque and, in Rome at least, not beautiful. All of the new buildings, indeed, are not even to be commended from a hygienic point of view, for many of them are so high as to shut off from their neighbors the sunlight which is here so peculiarly essential to the preservation of health. But the spoliation of the ruins of Rome is an artistic crime which finds no excuse on the score of hygienic necessity, and which no one but the most cobwebby and short-sighted archæologist can help execrating. The Thermæ of Caracalla and the Colosseum, which were once such marvels of beauty, with the climbing plants and brilliant flowering shrubs on their old walls, and the ilexes and almond trees in their open places, are now as cold and bare as the fire eaten remains of a Broadway dry-goods store. There was once a book written on the "Flora of the Colosseum," but now a day's hunt wouldn't reveal the presence of a blade of grass on those grim old walls. The same wanton destruction of all verdure has been going on all over the city, and even on its outskirts, and everywhere magnificent trees of a century's growth have been chopped down and cut up for fire-wood. The sight of modern Rome is a pain to those who knew the city but a quarter of a century since. Still Rome was not built in a day, and it is not to be destroyed in a day, and despite the vandalism of the past two decades the city is yet a delight to the painter and the poet, to the student of mediæval and ancient history, to the pagan and the Christian archæologist, to the lover of warm sunshine and brilliant skies, to the Catholic and to the non-Christian, to all who love whatever makes for beauty or suggestion in nature, in art, in the story of mankind.

The city promises to be more than crowded during the Congress week, in spite of the committee's optimistic assertion that there will be room for all who come. It is true that many of the non medical visitors will leave after Easter, yet there will be many here all through the month of April. Even now it is almost impossible to secure a

room at any of the leading hotels, and some of the boarding-house proprietors, with that happy insouciance or reckless greed that characterizes their class, have promised every hole and corner in their not too spacious apartments twice over. There are plenty of furnished apartments in different parts of the city still to be had, but it is not easy for strangers to find good ones at short notice, and they are, moreover, not very convenient for those who intend making only a brief stay. Nevertheless, as an indication of the pressure that there is already for room, the Secretary-General has an advertisement in to-day's paper calling on all those who have rooms to let in any part of the city to give notice at the office of the Congress, as there have already been many requests for them from members, and a special committee is scouring the city engaging whatever rooms are to be had for the Congress week. The attendance promises to be made up chiefly of Italians and Germans, though not a few French and English have signified their intention to be present.

LEPROSY AND VACCINATION — A LETTER FROM CALCUTTA, INDIA.

To the Editor of the Medical Record.

Sir: *Audi alteram partem* is a seldom practised adage when the mother country deals with the Western Atlantic tracts, and everything American is dubbed "That's Yankee, you know," and more or less pitched aside.

On page 708 of your December 2d issue, Dr. Beaven Rake says that I published a long series of cases (of leprosy) in which the data are too scanty to prove their connection with vaccination. I did nothing of the sort, and the facts are: Mr. W. Tebb published a pamphlet ("Public Health") wherein he made certain statements that I took exception to, and replied to in pamphlet form in 1891. This opened up a correspondence which resulted in my sending Mr. Tebb full medical histories of several lepers who were at that time under the observation of a fully competent committee of qualified medical men. From these histories Mr. Tebb (not I) published extracts which he embodied in pp. 191–9 of his "Recrudescence of Leprosy," which it is apparent Dr. Rake did not peruse carefully: else he would not have drawn the conclusions he now publishes in your columns.

When Dr. Rake was taken to task for the neglect displayed by the Leprosy Commissioners, he replied that he never heard of Dr. Chew's cases or he would have impartially (?) considered them (*British Medical Journal*, April, 1892); but he forgot to add "Mr. Wilson of the I. D. N. and the editor of the *Mohammedan Observer*, repeatedly called my attention to those very cases, but I ignored them" (vide *Indian Daily News*, June 11, 1891).

Now, sir, I am not ashamed of being a "Yankee," but knowing from experience the bitter criticisms I would be subjected to I made a point of thoroughly mastering Hindustani, and as I did not, like Dr. Rake, have to depend on "dubious" interpretation I was in a position to glean more definite information than he could. Before I attempted to write *causa morborum* against any patient I spent four or five hours in cross-examining each of my patients, even to the third and fourth generation of their antecedents, and demanding proofs of the statements made me. Consequently the conclusions arrived at by me are not so faulty as Dr. Rake, who knows practically nothing of India, pretends they are. (I have been out here for twenty-seven years.)

Dr. Rake repudiates vaccination as a factor in leprosy, but at the same time quotes instances where leprous infiltration has been proven to be consequent on vaccination. He ought also to remember that as termites change their form in accordance with the nutriment they receive even though they are the offspring of the same parent, so, also, do the bacilli lepra manifest differences in size, thickness, and activity, in compliance with the conditions of their surroundings.

The endemic theory does not hold when brought to bear on my cases, as not a single one of those that Dr. Rake holds up to ridicule belongs to a district where lepra is endemic; and, as a matter of fact, the majority of them were vaccinated when they came to Calcutta, and it was only on their return to their several districts (where the maps published by the Leprosy Commissioners show the least indications of lepra) that the disease manifested itself.

Lastly, as to the census returns for India, I am in a position to point out in Calcutta alone no less than fifty genuine lepers who were not included in that enumeration, and while Mr. J. A. Baines shows 127,056 lepers in the whole of India, and submits that only 173 of these were in Calcutta, the *Medical Reporter* of September 1, 1892, points out that at that very time there were, in and about Calcutta, the small number of 2,518 lepers; and Mr. H. F. T. Maguire, the Census Commissioner, complains in Sections 125 and 128 of his 1891 Report: "I do not pretend that the census for 1891 is a perfectly accurate one. Considering the difficulties in the way, and the men with whom I had to work, it has sometimes been a matter of surprise that any census was taken at all, or any returns prepared that could be accepted [Mind! not proven] as accurate." I therefore fail to see the grounds for Dr. Rake's deduction "There is thus an absolute 'decrease' of 4,604" (page 710 of your issue).

In conclusion, I trust you will do me the justice of publishing this letter, and thus disabuse the public mind of errors that are calculated to do much harm to the world at large if they be allowed to pass unchallenged.

I am, sir, yours truly,

Roger S. Chew, M.D., M S.C.

CHLOROFORM NARCOSIS — SHOULD IT BE TREATED BY THE APPLICATION OF ELECTRICITY TO THE PNEUMOGASTRIC?

To the Editor of the Medical Record.

I notice in the issue of the Medical Record, of February 24th, an article on "The Action of Electricity on the Pneumogastric—Is it of Value in Chloroform Narcosis?" by A. D. Rockwell, M.D., New York, which seems to invite a reply, and I venture some remarks.

The case which Dr. Rockwell reports was a child, aged six, on whom he was in the act of operating for nævus materni. He says: "She was chloroformed and needles introduced into the enlargement preparatory to the electrolytic action of the current, when suddenly the respiration ceased, the pulse became imperceptible, and the only evidences of life were very faint and convulsive heart-beats. A faradic apparatus was at hand, and one pole was immediately placed at the junction of the clavicle and the outer border of the sternocleido mastoid muscle, and a vigorous current applied. Evidences of returning vitality were seen almost immediately, and in a few moments the heart was again beating regularly. Did the electricity accomplish the good in this case, or, as some might claim, did the heart unaided resume its normal action?"

I am decidedly of the opinion that the heart unaided would have resumed its normal action, provided the respiration had been looked after. I am also decidedly of the opinion that a strong current applied to the pneumogastric during chloroform narcosis is dangerous. Why? It has been shown by physiologists that the pneumogastric is the cardiac inhibitory, and that a moderate faradic current applied to it slows the heart, a strong one stops it. It is true there are a few filaments of the sympathetic—cardiac motors—that join the pneumogastric, but the pneumogastric proper predominates. So, if the faradic current had been applied strong enough to have affected the pneumogastric, the heart would have been stopped rather than stimulated to better action.

Now, in this particular case before us, we have a patient under the influence of chloroform in whom respiration has ceased. Now let us look at the phenomena which present themselves when respiration ceases. When the oxygen is cut off, the exosmosis and endosmosis, by which there is an interchange of oxygen and carbonic-acid gases, cease. Consequently the blood is not relieved of its impurities, and becomes dark and thick. When it gets in this condition the circulation is very much impeded in the capillary system. The consequence is the capillaries first become engorged, then the arteries become engorged and distended, the blood dammed back to the heart, and its cavities rapidly distend. At first the heart beats regularly and is capable of emptying itself, but if respiration is not resumed again, in the course of a minute or two the heart becomes unable to empty itself, and the contractions become less and less frequent, and after a little cease altogether.

Now, in this case before us, we see the respiration ceased, and on account of the engorgement the heart was put to the convulsive movements referred to. So we claim that the application of the electricity did no good in this case, so far as the stimulation of the heart was concerned, but it may have stimulated the centre of respiration and caused a gasp of breath, as perchance a slap on the chest and abdomen with a cold wet towel would have done. Thus the respiration again started and relieved the engorged and distended heart. I also think that this case confirms the report of the "Hyderabad Commission."

On October 18, 1892, I was called to a boy, aged sixteen, whose foot had been run over by a large wheel of some kind, mashing the great toe almost off, and splitting the space between the metatarsal bones of the first and second toes back almost to the tarsal bones. He was at once chloroformed preparatory to amputation of the great toe and cleansing and stitching up the wounds. He seemed to be taking chloroform admirably, his heart was beating regularly at the rate of about 80 or 90 per minute, when all at once the pulsations became so rapid that I could not distinguish them apart at the wrist, and upon placing my ear to the chest I could just hear a flutter, such a noise as a partridge makes when flying up. I don't know, but I think his heart must have been going at the rate of about 250 or 300 per minute. I at once threw off the cone from which I was administering the anæsthetic, and in about thirty seconds the pulsations jumped down in a twinkle to about 90 per minute. I waited for some time, then cautiously began the chloroform again, but pretty soon had the same result. We then finished the operation without any more chloroform at all.

Now, what was the condition of this patient's heart, and what ought to have been done for him?

I compare his condition to that of an engine whose speed is regulated by a governor. As long as the governor is in good condition the engine runs smoothly and regularly, but if the governor belt runs off the engine "runs away." So in this case, I take it that the pneumogastric nerve is the governor of the heart, and when it became paralyzed from over-stimulation with the anæsthetic, the heart "ran away," as it were.

Now, if this be true, what good would a faradic current applied to the pneumogastric have done? It was paralyzed from over-stimulation, and we know that a nerve will not respond even to electricity when it has been already over-stimulated.

So I, like Dr. H. A. Hare (in his "Address on Medicine," before the Mississippi Valley Medical Association which met in Cincinnati, October, 1892), believe that the indiscriminate application of the faradic current to the pneumogastric in such cases is dangerous.

I think that in such cases, especially where respiratory failure is imminent, the best treatment is (although not new) to slap the chest and abdomen with a cold wet towel. If this does not cause the patient to gasp, then if a battery is at hand, attach a wire brush to the positive pole and sweep it across the chest and abdomen as you would in treating a case of opium poisoning. If this does not excite the respiratory organs to action, then commence vigorously to produce artificial respiration. By this means you can force enough air into the lungs to partially aërate the blood, so as to help its circulation through the capillaries, and furnish a stimulant (aërated blood) to the heart, lungs, and brain, which will bring about reaction.

Another remedy that is of very great value in the treatment of chloroform narcosis, or shock, is the hypodermic injection of large doses of strychnia; but don't fool with small doses, give decided doses, not less than one-twentieth grain, and if it is a desperate case one tenth, or even one-fifth grain may be given with impunity.

J. H. Blanks, Jr., M.D.

Meridian, Miss.

PURGATIVE TREATMENT OF TYPHOID FEVER.

To the Editor of the Medical Record.

Sir: Not having had any experience with the eliminative treatment in typhoid fever, I am not prepared to express an opinion on its advantages or disadvantages, but I would like to call the attention of my countryman, Dr. Thistle, whose article on the subject appears in your recent issue, to the fact that he must not claim to be the introducer of it to the profession. If he will turn to the pages of the *British and Foreign Medical Review* for October, 1841, he will find, at page 297, the notice of a work by Dr. De Laroque, Physician to the Necker Hospital, Paris, who announces in purgatives a panacea for typhoid fever, which he believes is the "mere product of the action of decomposing fluids in the alimentary canal." The reviewer states that M. De Laroque had gained a certain Parisian notoriety by treating "typhoid fever with purgatives in the morning, purgatives at noon, purgatives in the evening, and purgatives in the morning again."

Very truly yours,

William Osler, M.D.

1 West Franklin Street, Baltimore, Md.

DIGESTIVE PROTEOLYSIS.

THE CARTWRIGHT LECTURES FOR 1894.

BY R. H. CHITTENDEN, PH.D.,

PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN YALE UNIVERSITY.

LECTURE I.

PART I.—THE GENERAL NATURE OF PROTEOLYTIC ENZYMES AND OF PROTEIDS. INTRODUCTORY.

IN digestive proteolysis we have a branch of physiological study which of late years has made much progress. Chemistry has come to the aid of physiology and by the combined efforts of the two our knowledge of the digestive processes of the alimentary tract has been gradually broadened and deepened. That which at one time appeared simple has become complex, but increasing knowledge has brought not only recognition of existing complexity, but has enabled us, in part at least, to unravel it.

By digestive proteolysis is to be understood the transformation of the proteid food-stuffs into more or less soluble and diffusible products through the agency of the digestive juices, or more especially through the activity of the so called proteolytic ferments or enzymes contained therein; changes which plainly have for their object a readier and more complete utilization of the proteid foods by the system.

In selecting this topic as the subject for this series of Cartwright Lectures I have been influenced especially by the opinion that both for the physiologist and the physician there are few processes going on in the animal body of greater importance than those classed under the head of digestion. Further, few processes are less understood than those concerned in this broad question of digestive proteolysis, especially those which relate specifically to the digestion of the various classes of proteid food-stuffs, and to the absorption and utilization of the several products formed. Moreover, the subject has ever had for me a strong attraction as presenting a field of investigation where chemical work can advantageously aid in the advance of sound physiological knowledge; and certainly every line of advance in our understanding of the normal processes of the body paves the way for a better and clearer comprehension of the pathological or abnormal processes to which the human body is subject.

You will pardon me if I specially emphasize in this connection the fact that advance along the present lines was not rapid until physiologists began to appreciate the importance of investigating the chemico physiological problems of digestion by accurate chemical methods. Something more than simple test-tube study, or even experimental work on animals, is required in dealing with the changes which complex proteids undergo in gastric and pancreatic digestion. The nature and chemical composition of the proteids undergoing digestion, as well as of the resultant products, are necessary preliminaries to any rightful interpretation of the changes accompanying digestive proteolysis; but physiology has been slow to appreciate the significance of this fact, and, until recently, has done very little to remedy the noticeable lack of accurate knowledge regarding the composition and nature of the proteid and albuminoid substances which play such an important part in the life history of the human organism, either as food or as vital constituents of the physiologically active and inactive tissues. This is to be greatly deprecated, since our understanding of the nature of proteolysis, of the mode of action of the enzymes or ferments involved, and of the relationships of the products formed, is dependent mainly upon an accurate determination of the exact changes in chemical composition which accompany each step in the proteolytic process. How otherwise can we hope to attain a proper appreciation of the real points of difference between bodies so closely related as those composing the large group of proteids and albuminoids? Surely, in no other way can we measure the nature or extent of the changes involved in the various phases of proteolysis than by a thorough study of chemical composition and constitution, as well as of chemical reactions and general properties.

In the early history of physiology there was, quite naturally, little or no thought given to the nature of proteolytic changes. The gastric juice, as one of the first digestive fluids to be studied, was recognized as a kind of universal solvent for all varieties of food-stuffs, and this even long before anything was known regarding its composition, but beyond this point knowledge did not extend. Active study of the gastric juice, as you well know, dates from 1783, when the brilliant Italian investigator Spallanzani commenced his work on digestion. The names of Carminati, Werner, and Montégre[1] are also associated with various phases of work and speculation in this early history of the subject, especially those which pertained to the possible presence of acid in the stomach juices. In 1824, however, Prout showed conclusively that gastric juice was truly acid, and, moreover, that the acidity was due to the presence of free hydrochloric acid, and not to an organic acid. Still, many observations failed to show the presence of an acid fluid in the stomach, and it was not until Tiedemann and Gmelin's[2] masterly researches were published that the cause of this discrepancy was made clear. It was then seen that the secretion of an acid gastric juice was dependent upon stimulation or irritation of the mucous membrane of the stomach, and that so long as the stomach was free from food or other matter capable of stimulating the mucosa, it contained very little fluid, and that neutral or very slightly acid in reaction. These early observers also recorded the fact that the amount or strength of acid increased with the outpouring of the secretion, incidental to natural or artificial stimulation, thus giving a hint of the now well-known fact that any and every secretion may show variations in composition incidental to the character and extent of the stimulation which calls it forth.

The period between 1825 and 1833 was characterized especially by the presentation of the many results bearing on gastric digestion obtained by Dr. Beaumont on Alexis St. Martin, followed a little later, in 1842, by a long period of experimentation by many physiologists, as Blondlot,[3] Bassow,[4] Bardeleben,[5] Bernard,[6] Bidder and Schmidt,[7] and many others on methods of establishing

gastric fistulæ on animals, by which many interesting results were accumulated regarding the physiology of gastric digestion. Up to 1834, however, there was no adequate explanation offered of the solvent power of the stomach juice; aside from the presence of hydrochloric acid, nothing could be discovered by the earlier chemists to account for the remarkable digestive action. Eberle,[1] however, attributed to the mucous membrane of the stomach a catalytic action, and claimed that it only needed the presence of a small piece of the stomach mucosa with weak hydrochloric acid for the manifestation of solvent or digestive power. It remained for Schwann[2] to show the true explanation of this phenomenon, and although he was unable to make a complete separation of the active principle which he plainly believed existed, he gave to it the name of pepsin. Wassmann, Pappenheim,[3] Valentin, and later Elsässer,[4] all endeavored to obtain the substance in a pure form, and Wassmann,[5] in 1839, surely succeeded in obtaining a very active preparation of the ferment—one capable of exerting marked digestive action when mixed with a little dilute acid. Thus a true understanding of the general nature of gastric juice was finally arrived at, and the cause of its digestive power was rightfully attributed to the presence of the ferment pepsin and the dilute acid. Further, the analysis of human gastric juice made by Berzelius,[6] in 1834, showed that the secretion contains very little solid matter (1.26 per cent.), thus calling attention to the fact that the digestive power of this fluid is out of all proportion to the amount of pepsin, or even to the amount of total solid matter present, and consequently paving the way for a general appreciation of the peculiar nature of the dominant body, *i.e.*, the pepsin.

The original conception regarding the manner in which gastric juice exerts its solvent power on proteid foods was apparently limited to simple solution; chemical solution if you choose, brought about by catalytic action, but without any hint as to the possible nature of the soluble products formed. Mialhe,[7] however, recognized the fact that this transformation, by which insoluble and non diffusible proteid matter was converted into a soluble and diffusible product, was a form of hydration, comparable to the change of insoluble starch into soluble sugar, and he named the hypothetical product albuminose. Mialhe's study of the matter in 1846 was followed by Lehmann's[8] investigation of the subject, and the coining of the word peptones as an appropriate name for the soluble products of gastric digestion. The peptones isolated by Lehmann were described as amorphous, tasteless substances, soluble in water in all proportions and insoluble in alcohol. They were likewise precipitated by tannic acid, mercuric chloride, and lead acetate, and were considered as weak acid bodies, having the power of combining with bases to form salts of a more or less indefinite character. Twelve years later, in 1858, Mulder[9] gave a more complete description of peptones, but his study of the subject failed to advance materially our knowledge of the broader questions regarding the nature of the process, or processes, by which the so-called peptones were formed. A year later, in 1859, Meissner[10] brought forward the first of his contributions, and during the following three or four years several communications were made representing the work of himself and pupils upon the question of gastric digestion, or more especially upon the character of the products resulting from the digestive action of pepsin-hydrochloric acid

The general tenor of Meissner's results is shown in the description of a row of products as characteristic of the proteolytic action of pepsin-acid on proteid matter. In other words, there was a clear recognition of the fact that proteid digestion in the stomach, through the agency of the ferment pepsin, is something more than a simple conversion of the proteid into one or two soluble products. The several bodies then isolated were named parapeptone, metapeptone, dyspeptone, α, β, and γ peptone; names now seldom used, but significant as showing that at this early date there was a full appreciation of the fact that digestive proteolysis as accomplished by the ferment pepsin is an intricate process, accompanied by the formation of a series of products which vary more or less with the conditions under which the digestion is conducted.

This was the commencement of our more modern ideas regarding digestive proteolysis, but only the commencement, for it ushered in an era of unparalleled activity, in which Brücke, Schützenberger, and Kühne each contributed a large share toward the successful interpretation of the results obtained. Further, knowledge regarding the proteid-digesting power of the pancreatic juice was rapidly accumulating, thus broadening our ideas regarding digestive proteolysis in general. Corvisart[1] had called attention to the proteolytic power of the pancreatic juice in 1857, and although his observations were more or less generally discredited for a time, they were eventually confirmed by Meissner,[2] Schiff, Danilewsky,[3] and Kühne,[4] the latter particularly contributing greatly to the development of our knowledge concerning this phase of digestive proteolysis The proteolytic power was proved to be due to a specific ferment or enzyme, now universally called trypsin, which digests proteid foods to the best advantage in the presence of sodium carbonate. Digestive proteolysis in the human body was thus shown to be due mainly to the presence of two distinct enzymes, the one active in an acid fluid, the gastric juice, the other in an alkaline reacting fluid, the pancreatic juice, but both endowed with the power of digesting all varieties of proteid foods, with the formation of a large number of more or less closely related products.

So much for the early history of our subject, and now, without attempting any exhaustive sketch of its gradual development during the last decade and a half, allow me to present to you digestive proteolysis as it stands to-day, developed somewhat, I trust, by the results I have been able to contribute to it during the last twelve years.

General Nature of the Proteolytic Enzymes.—These peculiar bodies owe their origin to the constructive power of the gland-cells from which the respective secretions are derived. During fasting, the epithelial cells of the gastric glands and of the pancreas manufacture from the cell-protoplasm a specific zymogen or ferment antecedent, which is stored up in the cell in the form of granules. These granules of either pepsinogen or trypsinogen, as the case may be, are during secretion apparently drawn upon for the production of the ferment, and it is an easy matter to verify Langley's[5] observation that the amount of pepsin, for example, obtainable from a definite weight of the gland-bearing mucous membrane is proportionate to the amount of granules contained in the gland-cells. During ordinary secretion, however, these granules of zymogen do not entirely disappear from the cell. When secretion commences and the granules are drawn upon for the production of ferment, fresh granules are formed, and inasmuch as these latter are produced through the katabolism of the cell-protoplasm it follows that anabolic processes must be simultaneously going on in the cell, by which new cell protoplasm is constructed Hence,

as Heidenhain, Langley, and others have pointed out, during digestion there are at least three distinct processes going on side by side in the gland-cell, viz., the conversion of the zymogen stored up in the cell into the active ferment, or other secretory products, the growth of new cell protoplasm, and the attendant formation of fresh zymogen to replace, or partially replace, that used up in the production of the ferment. Consequently, we are to understand that in the living mucous membrane of the stomach there is little or no preformed pepsin present. Similarly, the cells of the pancreatic gland are practically free from the ferment trypsin. In both cases the cell-protoplasm stores up zymogen and not the active ferment, but at the moment of secretion the zymogen is transformed into ferment and possibly other organic substances characteristic of the fluid secreted. Absorption of the products of digestion tends to increase the activity of the secreting cells, but we have no tangible proof that any particular kinds of food are directly peptogenous, *i.e.*, that they lead to a storing up in the gastric cells, for example, of pepsinogen, although it may be that the so-called peptogenous foods give rise to a more active conversion of pepsinogen into pepsin.[1] As already stated, the zymogen is manufactured directly from the cell-protoplasm, and the constructive power is certainly not directly controlled by the character of the food ingested.

All this in one sense is to day ancient history, but I recall it to your minds in order to emphasize the fact that these two energetic ferments or enzymes stand in close relation to the protoplasm of the cell from which they originate. So far as we can measure the transformations involved, there are only two distinct steps in the process, viz., the formation of the inactive zymogen stored up in the cell, and the conversion of the antecedent body into the soluble and active ferment. In this connection Podwyssozki[2] has reported that the mucous membrane of the stomach exposed to the action of oxygen gas shows a marked increase in the amount of pepsin, from which he infers that the natural conversion of pepsinogen into pepsin is an oxidation process. Further, he claims the existence of at least two forms of pepsinogen in the stomach mucosa, one closely akin to the ferment itself and very easily soluble in glycerin, while the other is more insoluble in this menstruum. Langley and Edkins,[3] however, find that oxygen has no effect whatever on the pepsinogen of the frog's mucous membrane, thus throwing doubt on the above conclusion. Still, Podolinski[4] claims that trypsin originates from its particular zymogen through a process of oxidation, and Herzen[5] has proved that the ferment can be reconverted into trypsinogen under the influence of carbon monoxide and again transformed into the ferment by contact with oxygen gas. This latter observer[6] has also noticed a connection between the amount of trypsin obtainable from the pancreas and the dilatation of the spleen, from which he was eventually led to conclude that the spleen during its dilatation gives birth to a zymogen-transforming ferment which thus leads to the production of trypsin, presumably from the already manufactured zymogen. In any event, their peculiar origin lends favor to the view that these two enzymes are closely allied to proteid bodies, and that they are directly derived from the albuminous portion of the cell-protoplasm. Analysis shows that they always contain nitrogen in fairly large amount, although the percentage is sometimes less than that found in a typical proteid body.

It must be remembered, however, that in spite of oft-repeated attempts to obtain more definite knowledge regarding the composition of these proteolytic enzymes our efforts have been more or less baffled. We are confronted at the outset with the fact that no criterion of chemical purity exists, either in the way of chemical composition or of chemical reactions. The only standard of purity available is the intensity of proteolytic action, but this is so dependent upon attendant circumstances that it is only partially helpful in forming an estimate of chemical purity. My own experiments in this direction, and they have been quite numerous, have convinced me that it is practically impossible to obtain a preparation of either pepsin or trypsin at all active which does not show at least some proteid reactions. Furthermore, such samples of these two enzymes as I have analyzed have shown a composition closely akin to that of proteid bodies. I will not take time to go into all the details of my work in this direction, contenting myself here with the statement that the purest specimens of pepsin and trypsin I have been able to prepare have always shown their relationship to the proteid bodies by responding to many of the typical proteid reactions, and their composition, though somewhat variable, has in the main substantiated this evident relationship.

The most satisfactory method I have found for obtaining a comparatively pure preparation of pepsin, and one at the same time strongly active, is a modification of the method published some years ago by Kühne and myself.[1] The mucous membrane from the cardiac portion of a pig's stomach is dissected off and washed with water. The upper surface of the mucosa is then scraped with a knife until at least half of the membrane is removed. These scrapings, containing the fragments of the peptic glands, are warmed at 40° C. with an abundance of 0.2 per cent. hydrochloric acid for ten to twelve days in order to transform all of the convertible albuminous matter into peptone. The solution is then freed from insoluble matter by filtration and immediately saturated with ammonium sulphate, by which the pepsin, with some albumose, is precipitated in the form of a more or less gummy, or semi-adherent mass. This is filtered off, washed with a saturated solution of ammonium sulphate and then dissolved in 0.2 per cent. hydrochloric acid. The resultant solution is next dialyzed in running water until the ammonium salt is entirely removed, thymol being added to prevent putrefaction, after which the fluid is mixed with an equal volume of 0.4 per cent. hydrochloric acid and again warmed at 40° C. for several days. The ferment is then once more precipitated by saturation of the fluid with ammonium sulphate, the precipitate strained off, dissolved in 0.2 per cent. acid and again dialyzed in running water until the solution is entirely free from sulphate. The clear solution of the ferment obtained in this manner can then be concentrated at 40° C. in shallow dishes, and if desired the ferment obtained as a scaly residue. So prepared, the pepsin is certainly quite pure, that is comparatively, and although it may contain some albumose, the latter must be very resistant to the action of the ferment; indeed, pepsin is in many respects an albumose-like body itself.

In any event, the enzyme prepared in this manner shows decided proteid reactions, and contains nitrogen corresponding more or less closely to the recognized composition of an albumose. My own belief, therefore, is that these enzymes, both pepsin and trypsin, are proteid bodies closely related to the albumoses. They are soluble in water and more or less soluble in glycerin; at least glycerin will dissolve them from moist tissues, or from moist precipitates containing them. Langley,[2] however, states, and perhaps justly, that we have no positive proof that either ferments or zymogens are soluble in pure strong glycerin, and that if they are soluble, it is extremely slowly. In dilute glycerin, however, these ferments dissolve readily, as we very well know. Furthermore, they are practically non-diffusible, and, like many albumoses, are precipitated in part

by saturation with sodium chloride and completely on saturation with ammonium sulphate.

When dissolved in water and heated above 80° C. these enzymes are decomposed to such an extent that their proteolytic power is totally destroyed. The amount of coagulum produced by heat, however, is comparatively small, though variable with different preparations. Thus with trypsin, Kühne originally considered that boiling an aqueous solution of the ferment would give rise to about twenty per cent. of coagulated proteid and eighty per cent. of peptone-like matter. With the purer preparations now obtainable there is apparently less coagulable matter present, and Loew[1] has succeeded in preparing from the pancreas of the ox a sample of trypsin containing 52.75 per cent. of carbon and 16.55 per cent. of nitrogen, and yielding only a small coagulum by heat. Loew considered the ferment to be a true peptone, but in view of our present knowledge regarding the albumoses, I think we are justified in assuming it to be an albumose-l ke body rather than a true peptone. At the same time it may be well to again emphasize the fact that our only "means of determining the presence of an enzyme is that of ascertaining the change which it is able to bring about in other substances, and since the activity of the enzymes is extraordinarily great, a minute trace suffices to produce a marked effect. From this it follows that the purified enzymes which give distinct proteid reactions might merely consist of very small quantities of a true non-proteid enzyme, adherent to or mixed with a residue of inert proteid material."[2] This quotation gives expression to a possibility which we certainly cannot ignore, but my own experiments lead me to believe firmly in the proteid nature of these two enzymes. Further, we find partial substantiation of this view in the results obtained by Wurtz[3] in his study of the vegetable proteolytic ferment papain, and in my own results from the study of the proteolytic ferment of pineapple juice.[4] Thus, Wurtz prepared from the juice of Carica papaya an active sample of papain, and found it to contain on analysis about 16.7 per cent. of nitrogen and 52. 5 per cent. of carbon, while the reactions of the product likewise testified to the proteid nature of the enzyme. Martin, too, has concluded from his study of papain that the ferment is at least associated with an albumose.[5]

With the proteolytic ferment of pineapple juice my observations have led me to the following conclusions, viz., that the ferment is at least associated with a proteid body, more or less completely precipitable from a neutral solution by saturation with ammonium sulphate, sodium chloride, and magnesium sulphate. This body is soluble in water, and consequently is not precipitated by dialysis. It is further non-coagulable by long contact with strong alcohol, and its aqueous solution is very incompletely precipitated by heat. Placing it in line with the known forms of albuminous bodies it is not far removed from protoalbumose or heteroalbumose, differing, however, from the latter in that it is soluble in water without the addition of sodium chloride. At the same time, it fails to show some of the typical albumose reactions, and verges toward the group of globulins. In any event, it shows many characteristic proteid reactions, and contains considerable nitrogen, viz., 10.46 per cent., with 50.7 per cent. of carbon. Consequently, we may conclude that the chemical reactions and composition of the more typical proteolytic enzymes, both of animal and vegetable origin, all favor the view that they are proteid bodies not far removed from the albuminous matter of the cell-protoplasm.

Further, the very nature of these substances and their mode of action strengthen the idea that they are not only derived from the albumin of the cell-protoplasm, but that they are closely related to it. One cannot fail to be impressed with the resemblance in functional power between the unformed ferments as a class and cell-protoplasm. To what can we ascribe the particular functional power of each individual ferment? Why, for example, does pepsin act on proteid matter only in the presence of acid, and trypsin to advantage only in the presence of alkalies? Why does pepsin act only on proteid matter, and ptyalin only on starch and dextrins? Why does trypsin produce a different set of soluble products in the digestion of albumin than pepsin does? Similarly, why is it that the cell-protoplasm of one class of cells gives rise to one variety of katabolic products, while the protoplasm of another class of cells, as in a different tissue or organ, manifests its activity along totally different lines? The answer to both sets of questions is, I think, to be found in the chemical constitution of the cell-protoplasm on the one hand, and in the constitution of the individual enzymes on the other. The varied functional power of the ferment is a heritage from the cell protoplasm, and, as I have said, is suggestive of a close relationship between the enzymes and the living protoplasm from which they originate. We might, on purely theoretical grounds, consider that these unformed ferments are isomeric bodies all derived from different modifications of albumin and with a common general structure, but with individual differences due to the extent of the hypothetical polymerization which attends their formation.

Whenever, owing to any cause, the activity of the ferment is destroyed, as when it is altered by heat, strong acids, or alkalies, then the death of the ferment is to be attributed to a change in its constitution; the atoms in the molecule are rearranged, and as a result the peculiar ferment power is lost forever. The proteolytic power of these enzymes is therefore bound up in the chemical constitution of the bodies, and anything which tends to alter the latter immediately interferes with their proteolytic action. But how shall we explain the normal action of these peculiar bodies? Intensely active, capable in themselves of producing changes in large quantities of material without being destroyed, their mere presence under suitable conditions being all powerful to produce profound alterations, these enzymes play a peculiar part. Present in mere traces, they are able to transform many thousand times their weight of proteid matter into soluble and diffusible products. All that is essential is their mere presence under suitable conditions, and strangely enough the causative agent itself appears to suffer no marked change from the reactions set up between the other substances.

There are many theories extant to explain this peculiar method of chemical change, but few of them help us to any real understanding of the matter. These enzymes are typical catalytic or contact agents, and by their presence render possible marked changes in the character of the proteid or albuminoid matter with which they happen to be in contact. But the conditions under which the contact takes place exercise an important control over the activity of the ferment. Temperature, reaction, concentration of the fluid, presence or absence of various foreign substances, etc., all play a very important part in regulating and controlling the activity of these two proteolytic enzymes. In fact, as one looks over the large number of data which have gradually accumulated bearing upon this point, one is impressed with the great sensitiveness of these ferments toward even so-called indifferent substances. Their specific activity appears to hinge primarily upon the existence of a certain special environment, alterations of which may be attended with an utter loss of proteolytic power, or, in some less common cases, with a decided increase in the rate of digestive action. This constitutes one of the peculiar features of these proteolytic enzymes; powerful to produce great changes, they are nevertheless subject to the influence of their surroundings in a way which testifies to their utter lack of stability. Furthermore, as you well know, conditions favorable for

[5] The Nature of Papain, etc. Journal of Physiol., vol. 6, p. 336.

the action of the one ferment are absolutely unfavorable for the activity of the other, and indeed may even lead to its destruction. Thus, while pepsin requires for its activity the presence of an acid, as 0.2 per cent. HCl, trypsin is completely destroyed in such a medium. Again, trypsin exhibits its peculiar proteolytic power in the presence of sodium carbonate, a salt which has an immediate destructive action upon pepsin. Hence, a medium which is favorable for the action of the one ferment may be directly antagonistic to the action of the other.

Another factor of great moment in determining the activity of these two enzymes is temperature. That which is most favorable for their action is 38 to 40° C., and any marked deviation from this temperature is attended by an immediate effect upon the proteolysis. Exposure to a low temperature simply retards proteolytic action, doubtless in the same manner that cold checks or retards other chemical changes. There is no destruction of the ferment, even on exposure to extreme cold, the enzyme being simply inactive for the time being. Exposure of either pepsin or trypsin to a high temperature, say 80° C., is quickly followed by a complete loss of proteolytic power, *i.e.*, the ferment is destroyed. It is to be noticed, however, that the destructive action of heat is greatly modified by the attendant circumstances. Thus, fairly pure trypsin, dissolved in 0.3 per cent. sodium carbonate, is completely destroyed on exposure to a temperature of 50° C. for five to six minutes, while a neutral or slightly acid solution of the pure enzyme is destroyed in five minutes by exposure to a temperature of 45° C. On the other hand, the presence of inorganic salts and the products of digestion, such as albumoses, amphopeptone, and antipeptone, all tend to protect the trypsin somewhat from the destructive effects of high temperatures, so that in their presence the enzyme may be warmed to 60° C. before it shows any diminution in proteolytic power. Alkaline reaction, combined with the presence of salts and proteid, viz., just the conditions existent in the natural pancreatic secretion, constitute the best safeguard against the destructive action of heat, and under such conditions trypsin may be warmed to about 60° C. before it begins to suffer harm. But all this testifies in no uncertain way to the extreme sensitiveness of the ferment to changes in temperature; a sensitiveness which manifests itself, not only in diminished or retarded proteolytic action, but terminates in destruction of the ferment when the temperature rises beyond a certain point.

Similarly, pepsin dissolved in 0.2 per cent. hydrochloric acid feels the destructive effect of heat when a temperature of 60° C. is reached. In a neutral solution, on the other hand. destruction of the ferment may be complete at 55° C. Here, too, peptone retards very noticeably the destructive action of heat, especially in an acid solution of pepsin, so that under such circumstances the ferment may not be affected until the temperature reaches 70° C. I have tried many experiments along this line, not only with pepsin and trypsin, but also with many other ferments. We may briefly summarize, however, all that is necessary for us to consider here in the statement that the pure isolated ferments are far more sensitive to the destructive action of heat than when they are present in their natural secretions. This, as stated, is due not only to the reaction of the respective fluids but also to the protective or inhibitory action of the inorganic salts and various proteids naturally present. We may thus say with Biernacki[1] that the purer the ferment the less resistant it is to the effects of heat.

It is thus plain that these enzymes, capable though they are of accomplishing great tasks, are nevertheless exceedingly unstable and prone to lose their proteolytic power under the slightest provocation. When, however, they are surrounded by their natural environment, the acid or alkali of the respective secretion, together with salts and proteids, they then appear more stable; their natural lability becomes for the time being transformed into semi-stability, and the temperature, for example, at which they lose their peculiar power, is raised ten degrees or more. I have also found the same to be true of the vegetable proteolytic ferments, and also of the amylolytic ferment of saliva.

The above facts furnish us, I think, a good illustration of how dependent these proteolytic enzymes are upon the proper conditions of temperature, to say nothing of other conditions, for the full exercise of their peculiar power. Toward acids, alkalies, metallic salts, and many other compounds they are even more sensitive than toward heat, and much might be said regarding the effects, inhibitory or otherwise, produced by a large number of common drugs or medicinal agents on these two ferments. Any lengthy discussion of this matter, however, would be foreign to our subject, and I will only call your attention in passing to one or two points which have a special bearing upon the general nature of the enzymes. Take, for example, the influence of such substances as urethan, paraldehyde, and thallin sulphate on the proteolytic action of pepsin-hydrochloric acid[2] and we find that small quantities, 0.1 to 0.3 per cent., tend to increase the rate of proteolysis, while larger amounts, say one per cent., decidedly check proteolysis. Similarly, among inorganic compounds, arsenious oxide, arsenic oxide, boracic acid, and potassium bromide[3] in small amounts increase the proteolytic power of pepsin in hydrochloric acid solution, while larger quantities check the action of the ferment in proportion to the amounts added. Again, with the enzyme trypsin, similar results with such salts as potassium cyanide, sodium tetraborate, potassium bromide and iodide[3] may be quoted as showing not only the sensitiveness of the ferment toward foreign substances, but likewise its peculiar behavior, viz., stimulation in the presence of small amounts and inhibition in the presence of larger quantities.

Furthermore, we have found that even gases, as carbonic acid and hydrogen sulphide, exert a marked retarding influence on the proteid-digesting power of trypsin. Moreover, while it is generally stated that proteolytic and other enzymes are practically indifferent to the presence of chloroform, thymol, and other like substances that quickly interfere with the processes of the so-called organized ferments, pepsin and trypsin certainly do show a certain degree of sensitiveness to chloroform, and indeed even to a current of air passed through their solutions. Thus, very recently. Bertels[4] and Dubs,[5] working under Salkowski's direction, have called attention to the peculiar behavior of pepsin to chloroform; their results showing, first, that small amounts of this agent tend to increase the proteolytic power of the enzyme, while larger amounts decrease its digestive power. Another interesting point brought out especially by Dubs's experiments is the fact that an impure solution of the ferment. viz., an acid extract, for example, of the mucous membrane of the stomach containing more or less albuminous matter, is far less sensitive to chloroform than an acid solution of the purified ferment, thus showing again the protective influence of proteids and other extraneous matters, guarding the enzyme to a certain extent from both the stimulating and inhibitory action of various agents.

Another point to be emphasized just here is that any chemical substance, such as a metallic salt, having a specific action upon proteid matter, will almost invariably interfere more or less with the proteolytic action of these enzymes, both through a direct action upon the soluble ferment itself, and also through an indirect action in modifying or inhibiting the digestibility of the proteid exposed to proteolysis. All of these facts emphasize more or less the proteid-like nature of the enzymes, or at least the carriers of the ferments. It is further very suggestive that the destruction of these enzymes by heat hap

pens to occur at approximately those temperatures which are generally recognized as the coagulation points of ordinary proteids. Moreover, the apparent lack of stability so characteristic of these ferments, their inherent proneness to alteration, their marked susceptibility to every change in environment, all point to large complex molecules, such as we have in proteids and are familiar with in living protoplasm.

Whatever the exact nature of these proteolytic enzymes, they are certainly endowed with the power of transforming relatively large amounts of proteid matter into soluble products, even though they themselves are present in very small quantity. They are derived, as we have seen, from living protoplasmic cells, and we might perhaps, with v. Nageli[1] and Mayer,[2] consider them as retaining a portion of that molecular motion so characteristic of living protoplasm, by which the equilibrium of the dead food proteid may be disturbed and thus changes started which result in what we call proteolysis. However this may be, we must look to some phase of catalytic or contact action as the true explanation of this power of proteolysis. At first glance, any explanation or theory involving the use of catalysis seems exceedingly vague and indefinite, and yet many illustrations can be given of chemical reactions where the dominating agent evidently acts in this manner. "We call a force catalytic," says the philosopher of Heilbron, "when it holds no communicable proportion to the assumed results of its action. An avalanche is hurled into the valley. . . . A puff of wind or the fluttering of a bird's wings is the catalytic force which has given the signal for, and which is the cause of the wide spread disaster."[3] In the older theories of catalytic action, the catalytic agent was supposed to remain passive, but not so in the more modern conception of catalysis. The ferment by its presence makes possible certain changes and combinations which could not occur in its absence, at least under the existing circumstances, although all the other conditions might be favorable. The proteids, for example, have a natural tendency to undergo hydration; thus simple boiling with dilute acid or exposure to the action of superheated water alone,[4] will produce many if not all of the products formed in natural digestive proteolysis. To be sure, they are not formed as readily as in artificial or natural digestion, and there may be some minor points of difference, but still proteolysis can be imitated in this manner. The proteolytic enzymes simply help on this natural tendency of proteid bodies to undergo hydration, and by their presence and action enable it to occur at lower temperatures than it otherwise could, and at the same time render it more rapid and complete. This is not accomplished, however, by simple contact. The enzymes, we may assume, combine in some manner with the proteid undergoing digestion, starting thereby a train of reactions in which the proteid and the water present are the main actors, they being, however, perfectly passive in the absence of the inciting agent, the enzyme. As expressed by Gamgee, "the ferment phenomena resemble those in which there is apparently a periodic synthesis and dissociation of the catalyzing agent, which acts in a similar manner to the agent which explodes a train of gunpowder."

We can find many illustrations among chemical phenomena where one body, even though present in small quantity, acts as a go-between and makes possible an almost indefinite exchange of matter and energy. Take as an illustration, the part played by water in determining the explosion of oxygen and carbon monoxide gas. Some years ago, Dixon[5] called attention to the fact that a mixture of these two gases when perfectly dry would not explode even by contact with red hot platinum wire. The presence, however, of a small amount of aqueous vapor would at once cause an explosion to occur. In confirmation of this observation, Traube[1] has reported that a flame of carbon-monoxide gas introduced into a perfectly dry atmosphere is at once extinguished. In a moist atmosphere, on the other hand, the flame will continue to burn indefinitely, that is as long as the CO gas is supplied. In these cases, the water, which is so necessary for the appearance of the reaction, and which furnishes a striking illustration of the action of a contact or catalytic substance is not purely passive. To be sure, only a minimal amount is necessary for the combustion of an indefinite amount of carbonic oxide, but the water enters into the reaction itself. It is to be noticed that carbonic oxide and water alone, even at high temperatures, will not react, but in the presence of oxygen the water is decomposed with formation of hydrogen peroxide, thus:

$$CO + 2\,H_2O + O_2 = CO(OH)_2 + H_2O_2.$$

The hydrogen peroxide thus formed combines with carbonic oxide to form carbonic acid, which in turn is decomposed into the anhydride CO_2, with regeneration of water, the latter being available for further action of the same order:

$$H_2O_2 + CO = CO(OH)_2$$
$$2\,CO(OH)_2 = 2\,CO_2 + 2\,H_2O.$$

Indeed, as can be readily seen from the equations, this may be kept up indefinitely, a small amount of water, *i.e.*, the go between, the catalytic agent, sufficing to accomplish the transformation of almost any amount of carbon monoxide. This, I think, furnishes an excellent illustration of the way in which catalytic agents, such as the proteolytic enzymes, may be supposed to act. It is truly contact action, but the agent is not purely passive; the enzyme combines with the substance undergoing proteolysis, and the resultant compound thus formed is enabled now to combine with water and undergo hydrolysis, something which could not be accomplished by the proteid and water alone, that is at body temperature. This new and more complex compound is naturally less stable and soon undergoes dissociation or cleavage with a splitting off of the original enzyme for one product, which is thus available for further action of the same order; while, as other products, we find the hydrated and otherwise altered substances coming from the proteid, and whose formation is the ultimate object of the whole process.

The parallelism between this hypothetical action of the proteolytic enzymes and the known reactions in the above combustion of carbonic oxide is certainly very close and leaves little doubt that this explanation of enzyme action is, in a general way at least, correct. Thus the carbonic oxide, CO, brought in contact with pure, dry oxygen gas (apparently all this is necessary for its direct oxidation into carbonic acid, CO_2), undergoes no change; the burning CO gas is at once extinguished. Evidently, something more is necessary in order to start the process of oxidation. So, too, in proteolysis; the process, as we shall see later on, is essentially one of hydration, but bring the proteid and the water, or acid-water, together and although all the conditions are apparently favorable for hydration there is, as you know, little or no change. But introduce the catalytic agent and immediately the reaction commences. In the case of the burning CO gas in contact with oxygen, the water acting as contact agent makes oxidation possible, enabling the main actors in the transformation to react upon each other. But, as we have seen, the contact agent is something more than a mere looker-on, it becomes for the time being an integral part of the molecule, undergoing change, combining with it and thus making possible the subsequent alterations characteristic of the specific transformation, in which, however, the regeneration of the contact agent is a prominent feature.

[5] Chemical News, vol. 46, p. 151.

[1] Bericht. d. deutsch. chem. Gesellsch., Band 18, p. 1890.

So, too, with the proteolytic enzymes, pepsin and trypsin, they are the go-betweens, making possible the union of the proteids with water by combining with the proteid molecule and thus paving the way for both hydration and cleavage. In the cleavage of the complex molecule, we have the regeneration of the ferment as a prominent feature, and in proteolysis we understand that the regenerated ferment may act not only upon more of the original proteid, but likewise upon the primary products of its action, thus giving rise eventually to a row of more or less closely related cleavage products. Finally, we can conceive that the enzyme may gradually be affected by the process, that its regeneration may become less complete, and thus digestive power be eventually diminished.

Much more might be said in support of the above hypothesis. On the other hand, some objections might be raised against it, but I know of no more reasonable explanation of enzyme action than that here presented, or one which so well accords with all of the known facts concerning the conditions which modify proteolytic action.[1] Thus the influence of heat, of the products of proteolysis, of acids, alkalies, and various organic and inorganic salts on the action of these digestives enzymes is such as lends favor to the above view rather than opposes it.

(To be continued.)

The Chloroform of To-day.—In his last *Ephemeris* Dr. E. R. Squibb says: The same three prominent anæsthetics have maintained their standing throughout the entire forty odd years of the writer's experience, and have so far outlived the many substitutes that have been offered and used, that to-day ether, chloroform, and nitrous oxide are the anæsthetics of general use, as they were forty years ago. Neither have their relations to each other appeared to change very much. The use of all three agents has increased year by year, so that now each numbers its cases by tens of thousands.

In another most important respect their relative standing does not seem to have changed materially. Notwithstanding the increased care and skill that years of experience bring in the use of all agents, the fatalities from chloroform may still be estimated as about twenty to five from ether and to one from nitrous oxide, and the physician or surgeon who uses chloroform in cases where either of the other agents would be applicable has the same grave responsibility. This is a very singular condition of the usage, but it exists and persists, and seems to be generally accepted. About twenty years ago ether seemed to increase in use more rapidly than chloroform, and there seemed a chance that it would supplant the less safe agent, and confine it to special cases and uses, but during the last ten years chloroform seems to have recovered its prominence without sensible effect on its death-rate. Ether is certainly more used in this country, and its almost exclusive use in the general practice of hospitals shows that the enormous quantities of chloroform made and sold must be used in private practice.

In the *British Medical Journal* of July 29, 1893, p. 277, is found a "Preliminary Report of the Anæsthetics Committee," of the British Medical Association. This committee have records of 26,086 administrations of anæsthetics. Of these there were:

By chloroform	13,999
By ether	4,571
By gas and ether	2,001
By A. C. E. (alcohol, chloroform, and ether)	691
By gas and various mixtures and combinations	4,824
Total	26,086

Yeast Destroys the Typhoid Bacillus, or at least takes away its power for evil, so says Dr. Springthorpe, by means of an acid which it secretes.

Original Articles.

FURTHER OBSERVATIONS ON THE PHYSIOLOGICAL OCCURRENCE OF CONICAL STUMP AFTER AMPUTATION IN CHILDREN.[1]

By CHARLES A. POWERS, M.D.,

SURGEON TO ST. LUKE'S HOSPITAL AND TO THE CANCER HOSPITAL, NEW YORK.

In March, 1890, I presented before this Section a number of children whom I had seen in the hospital wards of Dr. Bull, and one boy who had been under my own observation. Each of these had suffered amputation of the arm above its middle, and each had developed a conical condition of the stump. Reference to the histories of these patients did not reveal a faulty technique at the time of the original operation, which could account for this condition, and I was forced to accept a physiological cause, namely, natural growth of the bone by elongation.

This conclusion was not original on my part. It had already been made by Verneuil, Bull, and others; but that it was generally understood or accepted would seem improbable, from the complete absence of reference to it in surgical text books or in special works on amputations.

At that time I made the following summary:[2]

1. Amputation through the arm or leg in children may be followed by a conical condition of the stump, and this sequel is a probability rather than an improbability.

2. This conicity may be physiological, and independent of inflammation or retraction in the soft parts, or of osteophytic deposit at the end of the bone.

3. The younger the child and the nearer the seat of the amputation to the upper epiphysis of the limb, the greater the probability of early conicity. These factors should be considered when making prognosis.

4. The weight of extant authority favors flaps of excessive length, but this measure may not prevent development of the conical condition.

5. When the conical condition is present, the only suitable treatment consists in the resection of a sufficient portion of bone.

6. Successive re-amputations may be required.

7. The above considerations may apply, but with very much less of force, to amputations through the forearm or thigh.

I have here an amendment to make to the above. Inflammatory deposit may take place at the end of the bone, this being due to pressure of this end against the tightly stretched skin. This deposit contributes but slightly, however, to the growth of the bone in length, the main part of which is due to the growth at the epiphyseal cartilage. Further, flaps of excessive length will very probably fail to prevent the conical condition.

A brief narration of the following cases may serve to strengthen the above conclusions.

Case I.—In January, 1892, I saw in the wards of Dr. R. F. Weir, at the New York Hospital, a boy,[3] six years of age, whose right arm had been amputated at the junction of its upper and middle thirds a year and a half before. The bone had grown down, the skin was adherent to its end and ulcerated (Fig. 1). An inch and a half of bone sawn off.

Under date of February 8, 1892, Dr. F. Ferguson, pathologist to the New York Hospital, writes me as follows regarding the pathological condition: "The material is a piece of the humerus of a child, measuring 4½ ctm. in length, and 1¾ ctm. in diameter, at one end, while the other end gradually tapers to a point. The medullary canal is present throughout, excepting a little less than the last 1 ctm. It is covered in places by soft tissues, but the bone very generally is devoid of periosteum; section through the small end shows, where it is covered by periosteum, that the periosteum is very greatly thickened

[1] Read before the Surgical Section of the New York Academy of Medicine, January 8, 1894.

[2] New York Medical Record, June 7, 1890.

[3] Case presented before this Section, February 8, 1892, unpublished.

and very dense in the arrangement of its fibrous tissue, but presents no evidence of recent inflammation. In the interior of the bone, at the end of the stump, there is considerable fibrous tissue, in the meshes of which there are many small round cells of inflammation. The stroma

FIG. 1.—Dr. Weir's Case.

of the medulla is also infiltrated with similar cells. The changes in the end of the stump are regarded as the result of the development of the bone, probably occurring in a physiological way, and pressure upon the soft parts."

CASE II.—Timmer[1] relates the case of a boy, aged fifteen, whose arm was amputated in its lower half eleven years previously; the bone gradually grew down, and produced a typical conical stump. Resection of bone.

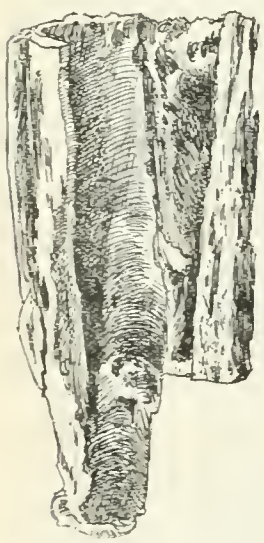

FIG. 2.—Cut Section of Bone from Dr. Weir's Case. The medullary canal is seen to extend to the end.

CASE III., by Mr. Owen,[2] of London.—"A boy, five years of age, put his right arm and forearm into a sausage-machine in March, 1884, with the result that amputation had to be performed just above the elbow. The ample flaps promptly united, and the boy went home. In October, 1889, he was readmitted because the stump had become conical and painful, and the bone was close against the scar. Chloroform being administered, the house surgeon, Mr. Hanson, removed about one inch and a half of the humerus from beneath the periosteum. The wound healed rapidly, and the boy returned home within a week. In a little more than a year he was again admitted, because the bone had grown too long for the stump. This time the house surgeon, Mr. Winter, removed two inches of the end of the humerus. And it is by no means unlikely that the boy will ere long be again admitted for a repetition of the operation.

[1] Nederl. Tijsch. für Genesk Anat., 1891, No. xxvii., p. 567.
[2] Lancet, October 3, 1891.

"Unless the fact be generally recognized that a conical stump is very apt to follow certain amputations in childhood, parents may be dissatisfied and the surgeon disappointed when a sawn humerus or tibia is found pressing against a tender and threadbare scar. Still, the occurrence is almost as physiological as that of the growing schoolboy's sleeves and trousers 'getting too short.' When amputation is done in the diaphysis the bone keeps on growing from its upper epiphysis, regardless of the fact that the skin and subjacent tissues have no provision for keeping pace with it."

CASE IV., by Dr. Lediard.[1]—"G. M——, a schoolboy aged fourteen, was admitted into the hospital on September 23, 1891. He had the left upper arm crushed seven years ago, and it was amputated some distance above the elbow. A conical stump resulted some years later, and three years ago Dr. Lediard resected the humerus, leaving ample flaps. On admission, the patient complained of the stump, which on examination proved to be conical, the bone protruding at the apex and causing pain. The skin was adherent to the bone. The bone protruded about half an inch. There was some pus. Over two inches of the humerus removed.

"The above account shows how active the upper epiphysis of this humerus has been, and it bears out the fact that conical stump is very apt to result in the arm after amputation in boys. It is curious that the bone seems to have grown more rapidly during the last three years than it did during the seven years previously. Unfortunately, it is not known how much bone was removed in the first instance, in proportion to the length of the flaps."

CASE V., by Dr. Bland Sutton.[2]—"Mary——, aged thirteen, came under my care suffering from a painful stump. When two years of age she underwent amputation of the leg at the junction of its upper and middle thirds, for injury. As she grew older the stump became painful, and at last so distressed her that she sought relief. I found the skin over the end of the stump red, tender, excessively thin, and the end of the tibia, which was pointed, nearly through the cicatrix. Amputation was performed at the knee-joint by the method known as Stephen Smith's.

"The cause of the stump becoming conical in this case is obvious; growth had continued at the epiphyseal lines, and gradually pushed the sharp ends of the bones through the thin tissue of the cicatrix. Most surgeons can recall similar conditions. Mr. Bryant mentions the case of a boy aged seven years, whose leg was amputated. Subsequently, on two occasions, at intervals of three years, it became necessary to remove a piece of the tibia an inch long; the tibia grew faster than the fibula, so that at the second operation the fibula required no shortening. So troublesome is this condition after amputation through the tibia in children, that I think it better practice to remove the leg at the knee."

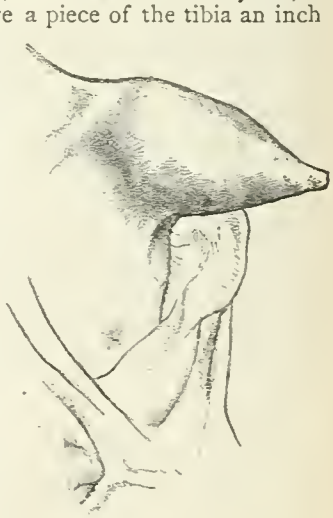

FIG. 3.

CASE VI.—Dr. J. A. Elliford, of Laurel, Del., writes me as follows: "I send you a tintype of a typical case of conical stump. Amputation through the upper third of the humerus for gunshot injury, when boy was twelve years old; operation by a competent surgeon; four years later, condition as seen in picture." (Fig. 3.)

CASE VII.—Dr. J. H. Finfrock, of Laramie, Wyo. Ter., writes me under date of June 22, 1890: "J. A——, aged eleven, had right arm crushed by a car-wheel July 19, 1892 (I copy notes made at the time). Amputation between

[1] Lancet, January 9, 1892. [2] Lancet, December 8, 1888.

upper and middle thirds. Liberal anterior and posterior flaps; one year later the stump was slightly conical, and continued to become more so for the following three years, at the end of which time he removed to Kentucky. I

Fig. 4.—Dr. McCosh's Case at Time of Original Amputation.

attributed the condition to a growth of the bone, and proposed to operate, but was refused an opportunity, as another physician had told the parents that I had cut the flaps too short at first."

Case VIII. is exhibited before you this evening by Dr.

Fig. 5.—Dr. McCosh's Case Three Years Later.

H. L. Shively. It is that of a little girl aged five, whose arm was amputated by Dr. Shively, three years ago, in the service of Dr. McCosh, at the Presbyterian Hospital.

In Fig. 4 the stump is shown directly after amputation. Fig. 5 shows the conical condition three years later, or at the present day. No comment on these pictures is necessary, the condition is a typical one. At the time of amputation, Dr. McCosh and Dr. Shively were good enough to speak to me of the case, and we watched the course with interest. We expected a development of the conical stump. Indeed, one may expect it in all similar cases.

Case IX.—Dr. L. J. Ladinski, of this city, writes under date of January 18, 1890, of a little girl, eight years of age, who was seen by him while on the house staff at the Mount Sinai Hospital, in 1889. The arm had been amputated at the middle, three years previously. When seen the stump was typically conical, and two inches of bone were resected.

Bruyelle, in a Thèse de Paris, 1887, relates histories of

Fig. 6.—Bruyelle Leg.

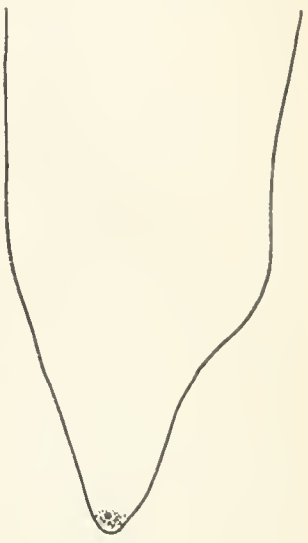

Fig. 7.—Bruyelle Arm.

four cases. The condition in two of these is shown by the reproduced tracings. Figs. 6 and 7.

I do not know that I have anything to add, by way of comment, to the narration of the foregoing cases. They would seem to strengthen, amply, the contention made in a previous discussion, namely, that after amputation through the upper part of the arm or leg in a young child, the slow development of a conical stump is to be expected.

35 West Thirty-fifth Street.

The Proper Care of the Sleeping-room should have a prominent place in the hygiene of the home. Every morning the windows should be opened, not a few inches, but wide, that the room may be filled with good, sweet air. Meanwhile the bed should be open, the clothes exposed to the air, and fortunate it is if the morning sunshine can lend its aid in purifying and revivifying. In the well-ordered house, where intelligent heed is given to healthfulness, the beds are not made early in the morning. The folding bed is undesirable for the reason that it is closed in the morning before the bedclothing has a chance to be aired. Day after day the bed-clothes, with their accumulated exhalations from skin and lungs, are packed tightly away, and when opened each evening at bedtime have a smell and feel not pleasant to one who is accustomed to a clean and well aired bed. Someone made the pertinent remark about beds, that people are afraid of clean damp, but not of dirty damp. The meaning is that they insist upon having everything from the laundry thoroughly aired before it goes upon the bed, but that after it is in use on the bed they fail to understand why the dampness and the foul exhalations should be dissipated every morning before the bed is made.—*The Sanitary Inspector.*

THE BARBER-SHOP AS A SOURCE OF CONTAGION.[1]

By GEORGE THOMAS JACKSON, M.D.,

INSTRUCTOR IN DERMATOLOGY, AND CHIEF OF CLINIC, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK; PROFESSOR OF DERMATOLOGY, WOMAN'S MEDICAL COLLEGE, NEW YORK INFIRMARY.

"NEXT!" How familiar the sound! How it brings up visions of past and present tonsorial artists who have tweaked our noses, cut our faces, and run the sharp point of their shears into the most tender parts of our necks. These same artists may have been black, with woolly hair; or brunette, with dark eyes and curly black hair; or large and blond, with flaxen locks; or short and thick, with high cheek bones and shocky hair; no matter whether he was negro, or Italian, or German, or Irish, or whatever his nationality, there was one common bond that bound them all, and that was a want of observation of the rules of personal hygiene.

As there are different nationalities among the barbers, so are there different grades of barber-shops, from the very cheap one in the cellar of the Bowery, where one towel is used for all customers, through that more pretentious one that displays a sign telling the passer by that every customer is entitled to a clean towel, and that a shave costs ten cents—with bay rum fifteen cents—up to such showy ones as that in Chicago, that boasts of being paved with silver dollars. Here, again, there is one common bond that binds them all, and that is, a want of observation of the rules of hygiene.

How often have you seen a barber with absolutely clean finger-nails? How often have you seen one that was particular in washing his hands after attending to one customer before going to the next? How often, in even the best of shops, have you found perfectly dry towels? How often has a feeling of disgust come upon you when you have had your hair brushed by a barber, and thought of what the conditions of the heads of the previous customers may have been upon whom the same brush had been used since last it was thoroughly washed and disinfected? If you have allowed the barber to use his hair-clipping machine upon you, have you ever thought how difficult it would be to disinfect that machine, and how very unlikely it was that such an idea as disinfecting it would enter the barber's head? What better means of infection could you invent than first to soften the epidermis with soap and water, then to scrape off some of the protecting cells with a razor held in hands whose nails harbor many a micro-organism, then to pat the tender, perhaps denuded, surface with a moist towel, and last of all, powder it with a powder-puff that has been in contact with unnumbered scores of faces?

And yet we, who are educated men, many of whom would perhaps hesitate to use the brush, comb, or other toilet utensil of a friend, submit to these things without a murmur, and even without a thought!

Most of you, perhaps, think of only one disease as contagious through the medium of the barber, that being ringworm of the beard and scalp. But, alas! that is but one of many. In the same list belong impetigo contagiosa, syphilis, sycosis, various forms of dermatitis, erysipelas, alopecia, alopecia areata, pediculosis, and perhaps acne frontalis, tuberculosis, and some others. Cases of all of these dermatoses have been reported by competent men as having their origin in all probability in the barber's shop. And as micro-organisms have been demonstrated in connection with all of them, why should they not be so communicated?

The agents of contagion are dirty finger-nails, the head-rest of the chair, damp towels, the shaving-brush, the razor, the powder-puff, comb, brush, sponges, and the hair-clipper. The most active carriers of contagion are, probably, the finger-nails, the towels, powder-puff, brush, and clipper. As the razor and the shaving-brush are dipped in boiling water from time to time, perhaps their dangers are somewhat lessened. We all know how hard it is to render the hands aseptic. We all remember Mr. Tait's historic remark in regard to the finger-nails and aseptic abdominal surgery. We all have noticed that the barber's finger-nails are often far from clean. As to towels, it is said, and doubtless with truth, that they are seldom boiled and washed after being used, but most usually simply put through the mangle, and then returned damp to the warm barber-shop to form most excellent culture media. And as to the clipper, we have already sufficiently remarked upon it as an instrument hard to disinfect.

Perhaps you are sceptical about the dangers that lurk in the barbers' shops, because you have not seen instances of contagion arising from them. I do not wish to pose as an alarmist, but I assure you that I am fully convinced of them, and if you are conversant with German and French literature, you must have noticed how our foreign confrères are fully awake to them. So much is this the case that in certain parts of Germany rigorous rules have been promulgated by the Government regulating the hygiene of the barber shops. In France epidemics of alopecia areata in regiments have been traced to the use of that infernal machine called the hair-clipper. Surely if there is any better instrument for spreading contagious disease of the scalp than this machine I do not know it. Do you?

This age takes just pride in its preventive medicine. Cholera, small-pox, typhus fever, and other contagious diseases have been greatly lessened and controlled by active preventive measures. The Board of Health in the city of New York, thanks to Dr. H. M. Biggs, has taken a long stride forward on this path in its recent resolutions as to the segregation of tuberculous patients. It is true that the diseases that may be spread by barber-shops may seem trivial when compared with the diseases just mentioned. But it is no small damage that is done to the child when he contracts ringworm of the scalp; or to the man when he loses all the hair from off the top of his head, or gets a chancre on his cheek.

It is useless to make laws unless public opinion is behind them. It seems to me that it is our duty as physicians and sanitarians to at once begin to educate public opinion in relation to the dangers that the barber-shops foster. When the people are aroused to a sense of their dangers it will be easy to formulate laws that can be enforced to mitigate and remove the evils to which I have had the honor to call your attention. There is one thing that can and ought at once to be done, and that is, to make it an offence punishable by fine to use the hair-clipper. Quite frequently do I see a patient with ringworm of the scalp in full bloom, whose hair has been clipped with a hair-clipper in the hands of a barber. Just think what mischief that barber may do in his ignorance!

I shall not attempt even to outline a system of rules for the hygiene of the barber-shops. I only hope that I have been able to sow the seed here that before long will bear fruit in correcting evils that have been allowed to exist too long, because public attention has not been drawn to them.

14 EAST THIRTY-FIRST STREET.

[1] Read before the Medical Society of the State of New York, February, 1894.

The First Chinese Medical College.—The first medical college worthy the name established by the Chinese Government was recently opened with formal ceremony at Tientsin. The project owes its origin to the intelligence and energy of the Viceroy of China and his wife, who constructed the necessary buildings and placed the direction in the hands of a distinguished graduate of the University of Dublin, selected by the late Sir Andrew Clark. The establishment of the college is attributed to the efforts of the Viceroy's medical attendant, Dr. Irwin, and to the influence of a Canadian woman, Dr. King. Some twenty well-educated English-speaking Chinamen have enrolled themselves as students, and the work of instruction has already been begun.—*Medical News.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, April 7, 1894.

THE INTERNATIONAL CONGRESS AT ROME.

THE International Medical Congress at Rome, of which we publish full cabled reports in our present issue, was in many respects a remarkable success. The attendance was large and reasonably representative, while the subjects discussed possessed in the main an interest commensurate with the wide scope of purpose and the high aims of such an august body. It was an imposing spectacle to witnesss thousands of medical men gather in the Eternal City, amid classical surroundings and mementos of ages long gone by, to renew history, to note progress, and to compare the civilization of the past with what it is at present. Science, strong with her centuries of training, bristling with brilliant discoveries, armed with demonstrated facts, widened with the broader views of humanity, came with its messages of peace and goodwill to men, with its assurance that the world is growing wiser and better, and with that helpful aid of wise counsel to state and king, to prove its right to command in the grandest and oldest of forums the best attention and highest respect of a listening world.

As each delegate felt a pride in bringing his best work it would not be surprising to learn that the presentation of the hundreds of original papers would aggregate a degree of excellence, finish, and worth which would be in ample keeping with the deep interests involved and the widespread influence at stake. Thus it was eminently becoming that the addresses before the general session should be of a character that appealed to the greatest number of thinkers, should touch largely on broad and comprehensive topics, and should more especially appeal to the necessity of focalizing dispersed efforts in the direction of proper organization and consequently more effective results. Consequently some of the addresses were quite suggestive of increased possibilities of advancement, especially in the direction of advocating governmental aid in scientific research and in the dissemination of useful knowledge thereby obtained. The opportunities offered for an interchange of views on matters of international import were also abundantly productive.

It is too soon to judge now of the lasting value of the scientific accomplishments of this Congress as compared with its predecessors. But in any event it is safe to say that many contributions of real importance to the medical world were made in the crowded section meetings and general assemblies.

In regard to the social features of this Congress, it was noted that they were arranged and carried out on a scale of unusual magnificence, all the more surprising in a country at present in the throes of acute financial distress. America was very meagrely represented, but in view of the great distance of Rome from the United States, and the perhaps rather unfortunate postponement of the original date for the Congress, this is only what might have been expected. Altogether the Eleventh International Medical Congress is likely to go down to history as a distinctly creditable and successful meeting.

AN ATTEMPTED LEGISLATIVE OUTRAGE ON THE ARMY MEDICAL CORPS.

IT is with indignation that all lovers of justice will look upon the latest endeavor of certain members of Congress to injure the efficiency of the Medical Corps of the United States Army by reducing its numbers thirty-five men.

This measure, now pending, is a pretentious attempt to gain credit for economy with political constituents; and the medical men are selected for attack because they, and more is the pity, do not combine politically for self-defence and are therefore a safe mark. In this case the bill is a most insulting one to these honorable physicians, implying, as it plainly does, that thirty-five of their number draw pay without earning it.

It is well that the facts of the case should be clearly formulated.

The Army Medical Corps consists of 193 members, attending to various hospital routine work, drilling the Hospital Corps detachment in field and in other duties, and ministering to the medical and surgical needs of the 28,000 soldiers constituting the present United States Army: and also attending their wives and families; the total of soldiers and adult male civilians at United States Army posts being to-day 43,431.

These 193 doctors are scattered over an area greater than all Europe, and divided among the one hundred and twenty military posts.

In event of field duty at any time, it is plain that one surgeon, at least, must accompany the troops from each post, and another should stay behind to take medical supervision of the hospital, and of the women and children. It will thus be seen how small—even too small—is the present corps.

Moreover, it occasionally happens that a doctor (being human) falls ill; and thereby reduces the effective list. Several are thus incapacitated at this time. And again, the law permits officers to take a month's vacation in each year without loss of pay. Therefore this reduces by one twelfth the list actively on duty; and about sixteen medical officers are thereby relieved for a time. As a matter of fact, such is the pressure of duty that the Surgeon-General must often refuse this well-earned vacation, compelling continual duty.

A simple calculation will suffice to show that these various factors, and the present five vacancies, reduce the number of the active medical corps much below its nominal strength of one hundred and ninety-three members; and should the present bill, removing thirty-five more, become a law, a grievous injury will be inflicted not only on the efficiency of the corps, but also on the soldiers and their families, who must look to the United States Medical Corps for attendance in sickness.

If it be alleged that contract surgeons—civilians—might be appointed to fill these vacancies at a lower cost, the reply is obvious; that there is now no appropriation made for contract doctors, though formerly this was the case; and even if there were, there is no provision of law whereby they can be placed in charge of the medical department at a military post.

Therefore they cannot take charge of the discipline and field drill of the Hospital Corps detachment, nor be responsible for the post hospital with its supplies.

To effect economy as far as practicable, the Surgeon-General has long employed only private physicians at all the arsenal posts in the country; these being small ones.

A further grinding down of medical estimates is worthy of the hearts and intellects from which the thought emanates.

Should this bill pass, it will of course stop the operation of the new Army Medical School, which is doing such good work, and which employs itself with the special education in sanitation of hospitals and troops, commissary knowledge, bacteriology, military surgery, and other subjects urgently needed by the new men among the assistant surgeons.

No further comment is needed, save the statement that upon March 15th the Commanding General of the United States Army, General J. M. Schofield, addressed a letter to the Secretary of War, stating that this bill would be "seriously injurious to the military service;" also, "the Medical Corps of the Army is none too large for the necessities of the service."

And yet it is considered likely that this measure will pass the House!

THE TREATMENT OF EPILEPSY BY GLASSES.

English ophthalmologists are slowly taking up the subject of the relation of eye-strain to epilepsy. In the last issue of *Brain* (Winter, 1893), Mr. H. Work Dodd publishes the results of the study and treatment of one hundred cases, with special reference to the ocular conditions. Examination of the eyes was made in one hundred normal and one hundred epileptic patients. Among the former were seventy cases of simple hypermetropia, while among the epileptics there were forty-two. On the other hand, he found some form of astigmatism among forty-two per cent. of epileptics, and only sixteen per cent. among the normal cases. He thinks, therefore, that in epilepsy there is an excess of astigmatism at the expense of simple hypermetropia. There were six cases of myopia in the epileptics, and only two per cent. in the normal, which is certainly a very low rate. The amount of emmetropia and metropia was about equal in the two classes. About two-thirds of the abnormal cases had dilated and sluggish pupils.

Of the two hundred cases, twenty-five did not need glasses, and twenty-three were lost sight of. Among the remaining fifty-two there were thirteen who had no fits, after wearing glasses, for periods varying from one year to four months; three were unimproved, and thirty-six were improved.

These results are rather striking, but do not bear close analysis. Many patients go for four months or a year without fits, yet are far from being cured. Mr. Dodd's cases continued to take bromide, and according to the text of some of his reports, attacks of *petit mal* occurred, although there were no "fits." In fact, the reports given are very much like those which are obtained whenever any new treatment is applied to a consecutive series of cases of epilepsy. We cannot consider that they show that glasses have any especial therapeutical efficacy, though they may afford some temporary relief, sufficient in some cases to justify their being used.

Curiously enough, Mr. Dodd seems to be quite unaware of the extensive labors of American ophthalmologists and neurologists upon this subject. And he does not refer at all to the muscular conditions of the eye, upon which so much stress is laid by some. Still his results seem to be just about as good as those obtained by the use of prisms and tenotomies.

THE INTERNATIONAL SANITARY CONFERENCE.

We learn by cable despatches that the International Sanitary Conference at Paris has completed its labors and has formulated rules in reference to the prevention of cholera which have a wide significance for good. At a time when there are grave apprehensions for the coming season, when the disease is already raging in Poland and Constantinople, it is most encouraging news to know that the strictest regulations are to be adopted in all those ports whence the plague is spread and in which previously no adequate precautions have been taken. Thus in all those places in India from which pilgrims for Mecca embark there is to be adequate medical inspection, the enforcement of disinfection and of all the other recognized sanitary regulations necessary for the maintenance of a proper health standard for the voyagers. All ships carrying pilgrims will be required to have a physician on board and a proper supply of pure water.

The Turkish lazarettos on the Red Sea are to be reorganized on a proper sanitary basis, and regular and thorough inspections are provided. The quarantine of pilgrim ships is to be so modified as to be reasonable without being oppressive, so that such as have clean bills of health will not be detained in quarantine longer than necessary for inspection, while in doubtful cases they will be held long enough to guarantee their safe liberation. Very thorough precautionary measures are to be taken in case of the pilgrims returning from Mecca, so that the inception and spread of the disease may be combated by the enforcement of all the known preventive measures. Thus virtually the very sources of the disease are attacked and a reasonable guarantee is offered that chances of dissemination will be reduced to a minimum.

The international character of the Conference, the tremendous interests it must necessarily exert, the degree of power for good which it represents, command for its suggestions the highest respect and give to its recommendations that moral force necessary to back the most stringent laws and to support the most radical measures. The Conference has been a success, and the prospect for the future is proportionately bright.

Women Physicians for the Insane.—The Virginia Legislature has a bill pending to cause the appointment of a proper number of women physicians to each hospital for the insane.

PATHOLOGY IN HOSPITALS FOR THE INSANE.

The eighteenth annual report of the New Jersey State Hospital for the Insane, at Morris Plains, is readable and interesting. The re-establishment of the Pathological Laboratory by the present medical director, Dr. B. D. Evans, was a step in the right direction. Dr. Thomas P. Prout, as resident pathologist, is doing creditable work. During the year just passed, thirty-eight autopsies were made. One case of choreic insanity was among the number. Microscopical examination of the brain cells in this case showed "granular degeneration with vacuolation to be features of some prominence." Fragmentation of the nucleus in the third and fourth layers was also observed.

In the report, illustrations are given in which nuclear vacuolation was present in two forms. Either a single large vacuole replaced the nucleus almost completely; or many smaller vacuoles were found scattered throughout the nucleus, giving it a honeycombed appearance. This destruction of the nucleus caused degeneration of the cell itself.

In studying the effect of normal fatigue on brain cells in insects and animals of the lower order, Hodge pointed out that vacuolation was a condition frequently observed.

News of the Week.

The Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons for 1894, will be continued at the New York Academy of Medicine, No. 17 West Forty third Street, on Wednesday evenings, April 11th and 18th, at eight o'clock, by Professor Russell H. Chittenden, Ph.D., of Yale University. Subject: Digestive Proteolysis.

Charity Work in Baltimore.—From the sixteenth annual report of the Presbyterian Eye, Ear, and Throat Charity Hospital, in Baltimore, we learn that the total number of new cases treated in 1893 was 10,941. In this institution the profession is generously represented on the staff of governors. It is a pleasure to note the courtesy of the latter in appending to the report the following tribute: "To the devoted attention of every member of the Surgical Staff of the Hospital is due the rapid growth of the charity, which, under their regular daily administration, has become one of the largest special hospitals in the United States. The personal sacrifices which they daily make, to be always prompt on time, is worthy of all praise; it has secured for each of them the confidence of the assembled throng of applicants for professional treatment."

The Association of American Medical Colleges.—The fifth annual meeting of the Association of American Medical Colleges will convene at Maple Hall, Grand Pacific Hotel, San Francisco, Cal., at 3 P.M., Wednesday, June 6, 1894. Action will be taken at this meeting upon the following amendments, to wit: Rush Medical College, by unanimous vote, submits the following amendment to Sec. V., Art. III., of the Constitution, "providing that of students who intend to graduate in 1899, or in subsequent classes, four years of medical study and an attendance upon four annual courses of lectures of not less than six months duration each will be required. Provided, that graduates of literary colleges who have taken a course of scientific studies, graduates of schools of pharmacy that require three years study and adequate preliminary education, and graduates of dental colleges requiring two years of study and adequate preliminary education, may be admitted to the second year's work or course of lectures in the college without examination." The present wording of Sec. V., Art. III., is as follows: "Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction of not less than six months duration each, in separate years."

A Correction.—The address of Dr. Edwin Barnes is Pleasant Plains, N. Y., instead of Pleasant Valley, as stated in our issue of March 18th.

Obituary.

CHARLES ÉDOUARD BROWN SÉQUARD, M.D., PARIS, FRANCE.

Charles Édouard Brown-Séquard died, in Paris, on April 2d. He was born on April 8, 1817, in the island of Mauritius. His father was a sea-captain, from Philadelphia, who married a French lady named Séquard. The son was sent to Paris, in 1838, to complete his medical studies, and received his degree in 1840. He then devoted himself to physiological experiments, so successfully that he received five prizes from the French Academy, and twice received the Queen's grant for the encouragement of science from the British Royal Society. His experiments decided important questions regarding the conditions and functions of the different constituents of the blood, animal heat (he fixed the temperature of the human body as high as 103° F.), the spinal cord in its normal and pathological state, the brain, the muscular system, the sympathetic nerves and ganglions, and the inhibitory and other influences of many parts of the body upon others.

Until 1864 he was active in London as head of the Hospital for the Paralyzed and Epileptic, and in 1858 he was honored by an invitation to deliver six lectures at the College of Surgeons. In 1864 he was appointed Professor of the Physiology and Pathology of the Nervous System, at Harvard College, which position he held four years, returning to France in 1869, and holding a professorship at the School of Medicine in Paris, until 1871. In 1873 he established himself as practitioner in New York.

During this period he lectured at Bellevue Hospital Medical College, and also gave a series of popular lectures on the "Brain."

He returned once more to Paris, in 1878, succeeding Claude Bernard in the chair of experimental medicine in the College of France. As a consulting physician he confined himself to diseases of the nervous system, being especially successful in the treatment of obscure diseases of the spinal column. He has published some of his writings in volumes entitled "Lectures on the Physiology and Pathology of the Nervous System," "Paralysis of the Lower Extremities," "Lectures on the Nervous Affections." In 1858 he established in Paris the *Journal de la Physiologie de l'Homme et des Animaux*, and in New York he issued, with Dr. Seguin, the *Archives of Scientific and Practical Medicine*. In 1881 he received the Boly medal from the Royal College of Surgeons, of London. While honoring him as an original investigator in various departments of their science, medical authorities have preserved a sceptical attitude toward his alleged discovery, in June, 1889, of a process of rejuvenating the body by subcutaneous injections of testicular extracts.

Society Reports.

ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

Held in Rome, Italy, March 29, 30, and 31, and April 1, 2, 3, 4, and 5, 1894.

(Special Report by Direct U. S. Cable to the MEDICAL RECORD.)

FIRST DAY, THURSDAY, MARCH 29TH — GENERAL SESSIONS.

THE inaugural session of the Eleventh International Medical Congress was held in the Costanzi Theatre, in the Via Firenze, on the morning of Thursday, March 29th. A brilliant assemblage was present, including King Umberto I. and his consort Queen Margherita, His Royal Highness the Prince of Naples, several members of the Italian Cabinet, the officers of the Congress, Drs. Baccelli, Pagliani, and Maragliano, and Commandatore Ferrando, the official delegates from all the civilized countries of the world, and a large concourse of members. Among the latter were Drs. Jacobi, C. Cushing, Lynch, J. B. Murphy, Kee, Spring, Ring, and Owen, from the United States; Stewart, from Canada; Sir Dyce Duckworth, Michael Foster, and others, from England; Virchow, Ewald, Klebs, Strümpell, and Ziemssen, from Germany; Kaposi, Lang, Lorenz, and Nothnagel, from Austria: Brouardel, Bouchard, Mouse, Cornil, Cezilly, and Gougenheim, from France; Babes and Petresen, from Roumania; Laache, from Norway; Stokvis, from Holland; Danilewsky, from Russia; Kocher and D'Espine, from Switzerland; Gyula Dollinger, Jendrassik, and Csatáry de Csatár, from Hungary; Lange, from Denmark; Ramón y Cajal, from Spain; Holmgren and Key, from Sweden; Hassan Pacha Mahmoud, from Egypt; Nazim Chéréffédin Bey and Van Millingen, from Turkey; Kitasato, from Japan; Marchiafava, Lombroso, Bizzozero, Durante, Semmola, Charles, and Rummo, from Italy; and many others. There were also many ladies, the wives and daughters of delegates and members, in the audience.

The meeting was called to order shortly after ten o'clock by the President, Professor Guido Baccelli.

Addresses of Welcome.—Signor Crispi welcomed the Congress to Italy and expressed in her behalf the high appreciation of the choice for such a meeting in her time-honored and classical capital. Science had assembled to add to her already numerous conquests, to record her wonderful progress, and take fresh courage for future work. Medical science worked for good in two ways, by preventing and by curing ills. Ancient Rome, the mother of all, gave civilization and law to the world, and now sends through science her message of peace and good-will to men.

The President, Professor G. Baccelli, followed in an address in Latin, in which he sketched the difficulties attending the civil and political rebirth of the nation, and how much the sympathies and good-will of other nations had been appreciated by Italy. During the celebration in Genoa all the nations sent war ships to honor Columbus, and now they sent scientists to strengthen the former bonds of humanity which unite anew Italy to the rest of the world.

In closing he cordially welcomed the august assemblage to classic Rome, where no one was really a stranger, and whose noble monuments were the real mementos of the achievements of the entire race, and were owned in common by the whole human family. The king and queen were ready to extend to them the freedom of the realm, the Italian ministers extended their cordial hand, while the citizen of Rome was honored by their presence. He then declared the Congress fairly opened.

Ruspoli, Mayor of Rome, gave a brief address welcoming the members of the Congress in the name of the city of Rome. From time immemorial physicians were always honored in Rome. Augustus made them citizens, and the title had legitimately descended upon all members of that glorious brotherhood, whether natives or strangers, so long as they walked her streets or occupied her homes.

Professor Rudolph Virchow, of Berlin, as President of the former Congress, made a short speech in which he claimed that Italy, in spite of numerous vicissitudes, always kept abreast with science: her students were always progressive, and her masters always illustrious. Ancient and modern Rome were linked to each other by scientific progress, and the present meeting was an expression of homage not only to ancient tradition, but to present fact. Physicians were the truest defenders of human rights in their care for the real safety and comfort of their fellows. Their humanitarian ideas, their unselfish work in the prevention of disease, their alacrity to aid in all times of direct need, made them the real peacemakers of the common brotherhood of mankind.

Professor D. Maragliano, the Secretary General, presented the report of the Organizing Committee, in which it was shown that nearly seven thousand members had registered.

Speeches of foreign delegates followed, in which greetings to Rome and the Congress were tendered in the name of their respective nations.

At the close of the session the King and Queen of Italy held an impromptu levee, receiving the Chairmen of the Foreign Organization Committees.

The sections met at three o'clock at the Polyclinic buildings outside the Porta Pia, for organization and the election of officers.

In the evening, at nine o'clock, the ruins of the Forum and its neighborhood were specially illuminated in honor of the Congress. There was a large attendance of members, and the streets around were crowded with people attracted by the novel sight. The lights were very skilfully arranged, throwing into brilliant relief the Arch of Septimius Severus, the few remaining columns of the Temples of Saturn, of Vespasian, and of Castor, Constantine's Basilica, the Arch of Titus, and the gloomy Colosseum in the distance.

SECOND DAY, FRIDAY, MARCH 30TH.

The morning hours, from eight to three, were taken up with the meetings of the different sections at the Polyclinic.

At four o'clock the first general session was held in the Eldorado, on the Via Genova.

The History of Medicine and Morgagni's Work.—Professor Virchow delivered an address on the history of medicine, in which he stated that the science of the healing art had slowly but steadily progressed for fully twenty-eight centuries. The problems sought to be solved comprised the factors of cause, prevention, and cure of disease. Numerous theories, based upon such facts as were known at different periods, successively offered themes for discussion and study. An initiative step was the recognition of humoral pathology. In the East a school arose introducing the spiritual element into crude science.

These two schools blended into one in Italy, where Galen, as its chief exponent, became almost a sacred authority. The slavish following of his teachings retarded substantial progress, especially in the study of anatomy. When dissection became permissible, valuable discoveries became numerous. Harvey demonstrated his theory of the circulation of the blood, and Malpighi that of the capillary system. Morgagni gave a still better direction to anatomical study by basing conclusions on personal experience, thus teaching his successors the true method of research. Hypothesis received its death-blow, and the study of the natural sciences became a declared fact. Morgagni inaugurated the system of localization of disease, which was the radical and necessary commencement for

logical study. He taught us to think anatomically, and thus became the founder of modern pathology.

At the close of the address Dr. Casati presented Virchow with a commemorative medal in the name of the citizens of Forli, the birthplace of Morgagni.

Reflex Fevers.—Professor Brouardel, of Paris, being unavoidably absent on account of illness, he was substituted by his colleague, Professor Bouchard, who delivered for him an address on the general subject of fevers, and their significance as indicating particular pathological lesions. In some instances, however, he was inclined to look upon the phenomenon as merely symptomatic, and apparently without associated lesion. Thus he had noticed that fever patients, when brought to the hospital, always had an increased temperature of one degree or more on the day of admission or the day following. This he believed to be due to mere nervous influence and was a reflex phenomenon, intended more to protect against any extra cold from external sources than to discharge a surplus of internal heat. The healthy man presented only slight temperature changes, as his vitality was greater and his adjustability was prompter and more actively resistant than the convalescent, whose slightest muscular effort was attended by proportionate temperature elevation. It was the relative intensity of the effort rather than its duration. The latter fact explained many curious phenomena, and established the existence of muscular fever, digestive fever, and nervous fever.

The State and Public Health.—Professor V. Babes, of Bucharest, then delivered his address upon the "Position of the State in Relation to the Results of Bacteriological Investigation." He began by saying that since health is the prime requisite to the happiness of the individual and to the development of human powers, it would seem as though it should be placed in the first rank among the work which it is in the province of the state to execute. Politicians are, however, at one in the view that government can concern itself only with that branch of sanitary science called "public health," and all agree that, despite its great importance, this is the least developed of all the administrative departments of European governments. The task which the orator had set himself was to point out the causes of this phenomenon, and then to indicate the means by which the department of public health might be raised to the position in the state to which it is entitled.

The speaker then reviewed the history of state medicine, recalling the fact that the earlier civilized communities, such as Sparta, Egypt, and Israel, were more practically concerned with the health of their individual members than modern states are or are willing to be. Much progress in the right direction has been made in recent times, but even now the most obvious precautions needful for the warding off of epidemic disease are sometimes wilfully disregarded in the interests of commerce.

After describing the Roumanian Health Institute and the work that is being done there, Dr. Babes cited a number of instances showing the services bacteriology has already rendered to the science of preventive medicine, and foreshadowing what great things might be done would the state but put to practical use the measures already proven, in the laboratory and by experience, to be effectual in warding off such scourges as tuberculosis, cholera, typhoid fever, rabies, and the like. These preventive measures might also be perfected and extended through the establishment of properly organized public health institutes.

When we compare the demands of the sanitarians with those of the politicians, we find that the latter almost entirely exclude from the functions of the state the duty of watching over the health of its citizens; and even when this is admitted in a certain degree, other public interests, which interfere with the proper execution of sanitary measures, are given the preference; the state concerns itself with the health of the individual only under certain exceptional conditions, and any interference with the family excites bitter opposition. Medical science will contend in vain with these conditions as long as it is not in a position to demonstrate practically the utilitarian results of modern bacteriological investigation. To this end it is necessary that we cut loose from all non scientific interests, and leave to others the task of safeguarding the rights of commerce, industry, statecraft, the army, and the family. Specially educated physicians, untrammelled by the duties of private practice, must come to the front to spread abroad in suitable places, especially in the legislative bodies, a knowledge of the conquests of our science and of their practical applicability. It is only in this way that sanitary science will attain the position which belongs to it by reason of its superlative importance in relation to the happiness of the people. The first results of such a propaganda will be the establishment of public health institutes, in which laboratory work can be carried out in the most complete and practically useful manner possible, and which will serve at the same time as high schools for the education of hospital superintendents, health officers, and all who will have to do with the carrying out of sanitary measures.

The persons so educated must make it their business to urge hygienic and social reforms, and to bring about the adoption of the principles that the question of individual health cannot be separated from that of public health, that the health of one class is a necessary condition to that of the other classes in the community, and especially that the health of the lowest classes is of vital importance in the social economy. As, however, ill-health among the lower classes depends more upon a lack of the necessities of life and well-being than upon the negligence of the state in the enforcement of the principles of individual hygiene and sanitation, it follows that the betterment of social conditions is a prime factor in the preservation of the health of the community. The sanitary interests of the laboring classes must be placed above the interests of capital and of competition.

The execution of sanitary measures must be wholly in the hands of state officials, but these officials must possess far greater technical knowledge than they do at present. The Department of Public Health must rank in importance with other departments of the government, but at the same time it must be politically independent, free from the interference of whatever party may be temporarily in power, and must be allowed the right of making and enforcing sanitary enactments in times of pressing need. The staff of the department must be large, and its officers must abstain from all political and professional activity outside of their own sphere. Under such conditions sanitary problems will be solved practically and scientifically, and the degree to which it shall be lawful and expedient for the state to interfere in questions of individual and public health will be definitely established. The state will have the right, indeed it will be its duty, to curtail directly or indirectly the liberty of the individual to live as he will, since modern investigation has shown that this restriction is necessary to the sanitary development of the community. Despite the fact that our present sanitary organizations can exercise their functions but imperfectly, and in some countries are almost powerless, some of them can more or less effectively put in execution, even now, certain rational measures, the results of which would demonstrate their potential utility could they but be more universally and strictly enforced. As soon as a sanitary measure has been anywhere shown to be good, or as soon as any discovery tending to the preservation or betterment of health has been made in the workshops of medical science, it will be the duty of the state to prove it, to turn it to practical use, and to popularize it.

Only thus will public health become a science, and that become a well-founded political science: only thus will the state, fulfilling the most important object of its existence, become a sanitary state.

In the evening there was a gala performance at the Costanzi Theatre.

THIRD DAY, SATURDAY, MARCH 31ST.

The Organization of Science.—The important business of the General Session on Saturday was opened by an address on "Organized Effort in Science," which was effectively and extemporaneously delivered by Professor Foster, of Cambridge, England. The subject was treated from practical stand-points, and telling illustrations were offered. The speaker maintained that there was an enormous waste of energy in the present methods of individualism in science.

More constant and systematized efforts were necessary to properly collate facts already known, and give them such wide dissemination as would prevent young, ardent, and inexperienced workers from losing time in verifying self evident propositions on the one hand, or in disproving palpable absurdities on the other. There was not time enough to go over useless ground.

Many young and enthusiastic workers labor assiduously but discover little, not knowing what to look for nor what to see. Many crude articles were published that should never see the light. A remedy for these ills was proper organization. In the Middle Ages every art had its guild. Why not revive the system for science? Then inquirers would meet masters and would be properly directed in their investigations; immature publications would then cease, and opportunities would be afforded for the collection of statistics on large scales and with definite purposes in view. But in order to make such things possible it was necessary to have international organizations. Such investigations are always expensive, and need to be widely distributive. It was time to organize now, and not wait for war before attempting to raise an army. An element in antagonism with organized advancement was the confusion in scientific nomenclature, but this could be easily remedied by an international tribunal. Much time could be saved to scientific students by the establishment of an international bureau, whose duty it should be to condense all useful articles into one publication for each branch of study. If such were impossible, complete and well-classified lists of titles might be frequently published. All such results were possible, however, only through national and international organizations.

Vital Adaptability to Pathological Processes.—Professor Nothnagel, of Vienna, next followed with an address upon the various processes by which the organism adapts itself to pathological losses, giving the well-known examples of repair of tissue in skin, muscles, tendons, and bones, the occurrence of vicarious functions, the work of two organs being often done by one, as, for instance, in the case of loss of one kidney.

Idiopathic Hypertrophy of the Heart and Degeneration of the Cardiac Muscle, was the title of the adress by DR. S. LAACHE, of Christiania, Norway. The pathology of the heart presents, as you know, this peculiarity, that we cannot go back with it to the "Father of Medicine," that ever young and living spring from which we so unceasingly draw. As a consequence of their preconceived ideas concerning the functions of the heart, the physicians of antiquity had formulated what now seems to us a paradox, the dictum that the heart itself could not become diseased. In these venerable times, in the very rare cases in which there was a question of cardiac trouble, the lesion was always referred to "polypi." During the whole of the Middle Ages, also, the true pathology of the heart remained a *terra incognita*. This ignorance is the more striking since it is in no way in harmony with the very clear and precise notions which had then been long held, concerning the anatomical structure of the heart and the affections of the neighboring organs, the lungs and the pleura.

To William Harvey belongs undying honor. Bonet also, with his "Sepulchretum," and others, still deserve to be worthily remembered. But, gentlemen, it was reserved to the country of which we are to-day the guests, to the Eternal City, to cast an effulgent beam of light into the depths of this darkness. Lancisi came, and his two works "De Subitaneis Mortibus," and "De Motu Cordis," bring us at once *in medias res*. The professor of Bologna, Albertini, deserves also to be saluted for all time as the founder of the science of cardiac diagnosis. Along with them we may also recall with gratitude the names of Vieussens, of Sénac, and others. It was, however, an entire century after Albertini that the famous author of "L'Auscultation Médiate," Laënnec, appeared and placed the crown upon the edifice.

There was henceforth an uninterrupted series of workers in this field. In the line of grand and unceasing advances made by the French school in the first half of this century, the pathology of the heart justly held always the first rank. In the number of the most brilliant leaders of this movement we soon meet with the name of Bouilland. But in proving the relation between endocarditis and rheumatism, this author made a discovery which was to a certain extent fatal to the studies which occupy our attention here, for the effect of it was to push too far in the foreground the cardiac valves and their diseases. This fact, joined to the unforeseen and important results furnished by the new method of auscultation, led clinicians to ignore the non-valvular, primary, idiopathic hypertrophies of the heart which had already been described—cardiac aneurisms, as they were formerly called, and some other affections in which the valves are not implicated. We find in this an explanation of how it was that Baur was thought to have made a new discovery when, in his Giessen thesis, published some thirty years ago, he described eighteen cases of hypertrophy of the heart without valvular lesion.

The disease soon became the fashion, and material for its study flowed in from all parts—from England, the United States, France, Russia, Holland, and elsewhere. The Scandinavian countries furnished also their modest contingent, but the most numerous and important works in this field have come to us from Germany.

How, now, shall we define our subject? It is impossible to give an exact definition of it in two words. We have in effect before us a clinical ensemble—a little vague, it is true—embracing a number of organic affections, differing among themselves, but all having one characteristic in common, namely, an enlargement of the heart and an absence of any discoverable anatomical—mechanical, if you prefer the term—obstacles to the circulation, and the fact that the valves remain intact, or that their lesions are in no sense proportionate to the other principal anatomical and clinical symptoms. The degree of enlargement of the organ may vary within very wide limits. It is here that we find the *cœur de bœuf* in its most characteristic form. But we should be very wrong to take into account only the degree of enlargement. A heart of great size may, as you well know, perform its functions in a satisfactory manner, while, on the other hand, an organ only slightly enlarged may do its work very ill. It is with the heart as with another hollow muscle of the organism, the stomach; what matters is not so much the absolute size, the dilatation of the organ, but the way in which it performs its duty, or, in other words, its insufficiency. For a certain number of cases no better designation can be found than the "weakened heart" of English writers, a term which has consequently and justly been introduced on the Continent to signify cardiac degeneration in its most general sense.

Etiology.—These affections offer much of interest as regards their etiology, because of the variety of their causes, especially from a hygienic, or, if you will, social, point of view, as compared with the valvular affections in the production of which rheumatism plays the most important rôle. Time does not permit me to enumerate all the predisposing causes, and I must limit myself to the mention of heredity, one of the three principal causes mentioned by Albertini, and secondly to those states which, in the language of Bouchard, are manifested by a retardation of nutrition.

Among the active causes there are especially two which

have been the subject of much discussion in recent years, viz., alcoholism and excessive muscular exertion.

Alcoholism is a factor of considerable importance, especially that form seen in beer-drinkers, which is, according to the interesting researches of Bollinger, a preponderating cause of so called pure idiopathic hypertrophy. The plethora provoked by the immoderate ingestion of beer, and the increase of blood-pressure resulting therefrom, furnishes an explanation of the increasing part—disputing the first place even with tuberculosis—which cardiac affections play in the mortality statistics of Munich. The "beer heart" constitutes certainly the sad reverse of the medal—I refer to the so justly celebrated Bavarian beer—but at the same time it furnishes a new and very interesting aspect of the multiple manifestations of chronic alcoholism.

Let us now pass to physical overwork, the injurious effect of which is so evident in all heart diseases that it was formerly regarded as sufficient in itself to provoke the most grave disturbances in the action of the cardiac muscle. Heart strain, *Anstrengung des Herzens*, holds, according to the majority of writers of the present day, a most important place among the exciting causes of non-valvular hypertrophy. All physicians, it is true, are not entirely in accord in this view. Nevertheless, even though it may be wise to be conservative, we can hardly admit any doubt as to the potency of this cause, if we consider the testimony furnished by the numerous and conscientious observations of such well-known writers as Fraentzel, Leyden, and others. Must we, however, draw from this the corollary that all muscular exertion a little in excess of the ordinary is to be forbidden, in order to avoid danger to the heart? By no means!

In order to put this subject in a clearer light, let us dwell for a moment upon a question which at the present time moves the spirit and stirs the activity of the entire world, that, namely, of "sport." Among us in Norway bodily exercise excited the greatest interest in remote times, the era of the Sagas and of the Vikings, when it was considered a cause for shame to die in a bed (*paa Lotteseng*), far from the field of battle. Later, physical exercise fell into disrepute, and, as in all mountainous countries, was practised only as an indispensable necessity of existence. For a long time the inhabitants of the cities took almost no exercise whatever. But that has all been changed. Now it is the youth of the cities, especially, who take the lead in athletic games, and not only grown men and boys, but young women also, even girls of six, eight, and ten years, and the latter do not let themselves be distanced by the others, you may depend. Almost all the young folks take sled rides (*Kjælkeagning*), skate, or still more frequently go snow-shoeing (*Ski*), during our long winter of four or five months. The summer sports are the same with us as elsewhere. This *Ski* exercise, or snow-shoeing, by means of which Dr. Nansen was enabled to cross the ice-fields of Greenland in 1888, demands considerable, and sometimes even enormous, muscular exertion under certain circumstances, especially when the ground is uneven. That this is so is very evident to anyone witnessing the annual races, in which it is not rare to see the contestants—not only the victor, even when he is an extraordinary runner, but also his less fortunate competitors—arrive at the goal completely out of breath, bathed in cold perspiration, with lips blue, and a pulse beating from 150 to 180 times a minute.

As a result of these observations, well calculated to awaken a certain degree of apprehension, the question of the sanitary aspects of athletic sports was made the subject of a discussion, some two years ago, before the Christiania Medical Society. One curious instance was related, that of a medical man who died suddenly just after his return from a snow shoe excursion. Some attacks—not many, however—of nervous origin were reported, and in addition there were a few cases, less than might have been expected, of traumatic injury. Not a single instance, however, of permanent disturbance of cardiac function was reported—this doubtless because of the general recuperative power of young persons, and of the reserve force latent in the heart itself. The physicians taking part in the discussion were in entire accord, however, as regards the dangers of an abuse of athletic games, and the evil that may result from their becoming too purely a matter of fashion; and also as to the necessity of imposing precautionary measures, especially an age limit, for those taking part in the races above referred to. Provided the individual acts reasonably and has prepared himself by a gradual course of training, the use of alcohol of course being forbidden, athletic games of various kinds ought to be regarded as not only allowable, but also—of this there can be no doubt—as the best means of tempering the muscles of the body in general and of strengthening the heart-muscle in particular.

We cannot close this chapter without saying a few words concerning intellectual overwork, a prolific cause of psychical enfeeblement, so frequent in our day, and which gives to this enfeeblement its fin-de-siecle character, masking it under an appearance of energy which, however, cannot conceal it from the eye of an attentive observer. In this period of electricity, of the telegraph, and telephone, the world progresses with lightning rapidity, and the individual succumbs all too easily in the struggle for existence as well as in the intellectual arena. The "fatigue of living" has presented itself as a ready subject for the pen of a psychological novelist.[1] And in fact we may justly establish the existence of a cardiac weakness, a "heart tire," alongside of the "brain tire" long since admitted as a current expression in language.

It follows, gentlemen, from what has been said above, that the affections which we are now considering are in large part diseases of *civilization*, and that we must look for them among the inhabitants of large cities rather than in rural districts. If on the one side their relation to alcoholism and physical overwork makes their occurrence very common among the lower classes, on the other there are many causes, such as a sedentary life, overeating, the abuse of tobacco, debauches and excesses of every kind, which tend to render it a not infrequent malady among the leisure classes, even among individuals the highest in the social scale.

Symptoms.—The symptomatology of these affections follows naturally in its ensemble the laws governing that of valvular troubles, but yet the non valvular diseases are peculiar in that they are often so insidious in their onset, and, as it were, masked, that their diagnosis presents great difficulty. As a venerable colleague once said to me, basing his remark upon the results of a long experience: "It is these very affections of the heart whose diagnosis is the most difficult that are the most dangerous."

The examination of the pulse is naturally first made. It may be normal, but the contrary is not rare, the anomalies consisting in irregularity or in an abnormal retardation of pulsations. I will not take up your time in discussing all the details of the diagnosis, so interesting to the clinician and to the physician in his daily practice, but will pass to a brief consideration of the prognosis of this class of cardiac affections.

The prognosis of hypertrophy of the heart, which seems almost inevitable to the lay public, is sudden death. As you know, it is generally maintained that this mode of decease has greatly increased in frequency in our days, and it is probable that the belief rests upon some foundation of fact, although statistics on this point are wanting. In fact, one can hardly open a newspaper without seeing an account of the unexpected death of some one or other, due, it is said, to paralysis of the heart. We must not forget, however, that every event now finds publication, and the before-mentioned work of Lancisi shows us that sudden death was not unknown even in his time. Sudden death is, however, by no means the necessary termination of these affections, the very contrary being often noted. We may even assert that the diseased heart manifests, under certain conditions, a power of resistance which is almost incredible, justify-

[1] Arne Garborg: The Fatigue of Living. Christiania. 1892.

ing the term, *ultimum moriens*, applied by Haller to this organ.

Treatment.—We will sketch briefly only a few points of the treatment of these affections. When, to use a popular expression, the heart is found to be failing, our object must be, as you well know, to establish a condition of compensation and then to do everything possible to maintain it. This end may be reached in various ways. Among the medicinal remedies proposed—their name is legion—for the regulation of the secretions, we employ here also, according to the circumstances in each case, digitalis, iodide of potassium, strophanthus, etc., the last named generally so inoffensive though efficacious.

The method of treatment, consisting in exercise and training of the cardiac muscle, is one that was formerly employed especially in the case of the corpulent and of those of the upper classes whose only mode of progression was in carriages. But the opposite method, that of sparing the heart as far as possible, is the one that was usually employed by the physician, and to which patients themselves instinctively turned; indeed, we may say that the modern symptom of heart-training owes its origin to the results of the experiments of Oertel as recounted in his work, which is familiar to you all.

The most important thing, however, is the prevention of the disease, and this is within the possibilities of all. The necessary measures of prophylaxis may be gathered from what has been said before in the section dealing with the exciting causes of this form of cardiac affections.

You may remember, gentlemen—to borrow an image from Roman antiquity—that Menenius Agrippa, in his celebrated apologue to the people before the war against Volsgians, characterized the stomach as the organ *par excellence* from which all the members derived their sustenance. That was well enough, but from a physiological point of view, and by better right, it is the heart which we ought to regard as the centre whence the strength-giving and nutritive sap flows to all parts of the human frame.

The science of hygiene has hitherto successfully grappled with the problems dealing with the lungs, the digestive organs, and the nervous system, but it has perhaps neglected to take into sufficient account those relating to the heart. Let us hope that the time is coming when it will no longer be open to this reproach.

Would it not, reflect for a moment, be a noble mission to go into an exhaustive study of the hygiene of this noble organ, and thus to realize the very ideal of the subject of our discourse: *Cor sanum in corpore sano?*

FOURTH DAY, SUNDAY, APRIL 1ST.

There was no scientific work on this day, the time being left free for excursions and sight-seeing.

FIFTH DAY, MONDAY, APRIL 2D.

Receptions.—At 9 P.M. the Municipality of Rome tendered a reception to the members of the Congress and their ladies at the Campidoglio. This square of the capital, so rich in historic associations, was brilliantly illuminated for the occasion, and the bronze statue of Marcus Aurelius, astride his magnificent charger, in the centre of the piazza, witnessed a sight unusual even for Rome, the city of spectacles. The Palazzo del Senatore, standing on the remains of the ancient Tabularium, was thrown open for the accommodation of the city's guests, who filled the spacious hall and the rooms adjoining. No general session was held this day.

In the afternoon a garden party was given to the visiting physicians and their wives, by the King and Queen of Italy, in the gardens of the Quirinal Palace. These gardens, to which the public is now very seldom admitted, are delightful in the quaint oddity of their stiff box hedges, the charming glimpses which they afford of the dome of St. Peter's and other prominent objects in the city and surrounding Campagna, and the little unexpected finds of fountains, statues, and whimsical devices, such as an organ played by water, upon which the wanderer is constantly stumbling. Although the gardens are quite spacious, about three-quarters of a mile in circumference, they were well filled by the guests of their Royal Majesties, who strolled by twos and threes along the smooth gravel walks, bordered with high green walls, and listened to the music from one of the best of the regimental bands.

SIXTH DAY, TUESDAY, APRIL 3D.

Growth and Regeneration.—PROFESSOR BIZZOZERO, of Turin, gave an instructive address on this subject. He began by passing in review the most important discoveries of recent years bearing on the topic under consideration. He alluded to the growth and repair of tissues under normal conditions. According to him all the tissues of the human body might be divided into three groups. In the first group he placed those histological structures whose component elements multiplied throughout life. These showed continuous regeneration during the entire natural life of the individual. The spleen, the glands, and the marrow of the bones were given as instances of this class.

The second group comprised those structures the constituent elements of which multiplied up to, and occasionally for some little time after, birth, and then stopped, no further regeneration taking place. The liver and kidneys belonged to this group.

Under the third group the reader included those tissues which did not increase numerically after the embryonal period was ended. Nerve-cells and muscular fibres were given as examples of this class of structures.

Continuing, the reader passed in review the more recent discoveries relating to regeneration of tissues under pathological conditions. In all glandular bodies this regeneration was very active.

In smooth muscular tissue it was less so, and finally in nerve-cells and striated muscles it was not observed at all. These observations accorded with the differences previously pointed out in relation to these various structures.

He next turned to the question touching the part taken by the blood-vessels, lymphatics, nerves, and tissue elements in processes of repair. Morpugo, as was well known, had found that the hyperæmia following division of the sympathetic favored repair after wounds. Penzo had demonstrated that warmth favored regeneration in epithelium and sebaceous glands, but not in connective tissue and cartilage. All these results were even more prominently seen in growing animals.

In the repair of fractures the beneficial results of heat had been amply shown.

He did not believe that the existence of trophic nerve-fibres favoring nutrition and repair of elements had been demonstrated by experiments and unimpeachable clinical observations. Diseases supposed to be due to lesions of trophic nerves might easily be explained otherwise. Facial hemiatrophy, for example, was easily accounted for by vaso motor alterations. All circulatory changes predisposed the parts to the action of pathogenic influences. This fact might explain the origin of certain other nervous troubles, such as herpes zoster. In such a disease as ichthyosis an increase of nutriment might favor an already existing proliferation, but could not excite it *de novo*.

In extra uterine life the tissue elements increased and multiplied from the same cause as in fœtal life, before the establishment and differentiation of the nervous system and blood-vessels. The same causes were also active in the repair of morbid destruction of tissues. The reparative power was inherent in the tissues themselves. It was only modified, but never initiated by heat, the blood-supply, and other agencies.

He had only considered growth and repair, but there

was no doubt that pathological proliferation was effected in the same way. Virchow's doctrine was the only conceivably true one. It was always the cell alone that lived and responded to outside irritants or stimulation.

Biological Importance of Phosphorus in its Organic Combinations.—Professor Danilewsky, of St. Petersburg, delivered an address on phosphorus and its organic combinations. He assumed that protoplasm was the basis of every vital phenomena, was largely composed of albumin, and was directly influenced and modified by various substances for which it had an affinity, as, for instance, alcohol, arsenic, opium, and phosphorus. The latter was a leading factor in the modification of vital phenomena, and its importance in explaining the existence of modified and complex conditions could hardly be over-estimated.

Seventh Day, Wednesday, April 4th.

Non Nocere—Harm Not.—Professor A. Jacobi then delivered an address having the suggestive title of Non Nocere. In speaking of the harm that might come to the International Medical Congress, he glanced at the ominous predominance of the social element and the threatened neglect of the scientific work. There was a neglect in the study of special branches at the expense of progress in general medicine. Many of the so called specialists were untrained men, and others calling themselves scientific men were given to accepting and even advocating proprietary medicines and food nostrums, encouraging fads of sensational treatment of tuberculosis, cholera, and senility. Harm was also done by rash surgical and gynecological interference, while over-dosing was just as bad, as well as the so-called expectant treatment. The latter was often a convenient cover for incompetency and ignorance. Harm was often done by neglecting intubation and tracheotomy at critical junctures. Diseases like pertussis, which could be shortened, must be treated to prevent complications; eruptive diseases be watched and treated to avoid mental disturbance or collapse. Pneumonia may require venesection to save life. In convalescence strong stimulants and great care are needed, and so called maximum doses were safeguards more for the physician than the patient. He then spoke of the senseless over- and under-feeding of infants, the evil effects of excessive sugar in their foods associated with acid catarrh, while sterilized milk as the only food was highly objectionable. The neglect of asphyxia neonatorum led to cerebral disease and idiocy, and by want of care in asepsis wound-infection in the new-born often occurred. The so called chronic constipation in infants was due to extra length of sigmoid flexure. Unless this was correctly treated, enteritis, and auto infection with fever followed. The difficulty corrected itself during the sixth or seventh year. Harm was done in diphtheria by forced applications to struggling children. He had collected thirty-three cases of craniotomy for idiocy and macrocephalus, and found that the results were always negative. A skull in Sach's possession proved the existence of contraction rather than enlargement of cranium as the result of operation.

Chemistry in its Relation to Pharmacy.—Professor Stokvis, of Amsterdam, delivered a scholarly address on the relations of Chemistry to Pharmacy. Therapeutics was formerly the leading art in medicine, but had become distanced by surgery, which lately had developed itself almost to an exact science. He reviewed the most recent discoveries bearing upon the action of different substances upon protoplasm. Such might not profit the healing art as yet, but the future was reasonably bright and could be watched and studied with becoming hopefulness.

New lines for experiment were marked out, but it was premature to assume that they could furnish us with all the active principles for our therapeutics. It was still problematical whether more certain results could be promised from alkaloids than pure drugs, which might be more judiciously mixed. The new remedies and synthetical compounds so alluringly advertised must be more thoroughly tested before they are unqualifiedly indorsed, and due opportunity must be afforded for chemistry to vindicate itself in this line of research.

In the evening, at seven o'clock, the dinners of the sections were served in various hotels and restaurants throughout the city. They were numerously attended.

Eighth Day, Thursday, April 5th.

The closing session of the Congress was held at nine o'clock. At twelve o'clock a lunch was served to the members and their ladies in the grand roofless halls of the Thermæ of Caracalla. This magnificent ruin, which surpasses in some respects even the Colosseum in its majesty, was filled with a throng of Barbarians gathered from all quarters of the globe. The gilded youths who once frequented in thousands this club (for such it really was) would have rubbed their eyes in blank amazement to see this assembly of learned men and graceful women from Gaul, the British Isles, and far Atlantis, the latter sweeping with their trains the dimmed mosaics of the tessellated pavement and the floor of the now drained frigidarium. Here, where in the days of imperial luxury, the dissolute descendants of the conquerors of the world were wont to idle away the hours of the waning day in riotous feasting and enervating baths, a feast was once again spread, and around it was gathered an army whose legions are battling to save life instead of to destroy, whose god is Mercury and not Mars, whose conquests will once more unite the world, not under the thraldom of an imperial master, but in the bonds of a universal brotherhood of health-givers, worthy worshippers at the shrine of Esculapius, on the Isola Tiberina.

In the afternoon a battle of flowers, such as used to mark the closing day of the carnival, was held in the Corso, and a boat race took place on the Tiber. Soon after the Ave Maria, in the gathering darkness of the night, came the beautiful "ritirata dei moccoletti" (a candle-light procession familiar to visitors in Rome), signalling the close of the International Medical Congress of 1894.

Further details of the congress will appear in future issues.

Opposed to the Registration of Tuberculosis.—At a recent special meeting of the College of Physicians of Philadelphia, the question of registering cases of tuberculosis was fully discussed and the following action was taken:

Resolved, That the College of Physicians believes that the attempt to register consumptives and to treat them as the subjects of contagious disease would be adding hardship to the lives of these unfortunates, stamping them as the outcasts of society. In view of the chronic character of the malady, it could not lead to any measures of real value not otherwise attainable.

That strict attention on the part of physicians in charge of the individual cases, insisting on the disinfection of the sputum and of the rooms, on adequate ventilation, and on the separation of the sick from the well as far as possible, will meet the requirements of the situation so far as they practically can be met, and better than any rules that, for diseases so chronic, can be carried out by a Board of Health.

That the College of Physicians respectfully requests that no official action be taken in the matter by the Board of Health, except the insisting on the disinfection of rooms in which consumptives have lived and died, in instances in which such procedure is not likely to have been adopted under the direction of the attending physician.

A Simple-minded Man writes to an English contemporary to inquire whether it is proper for members of a medical society to consult with herbalists.

Reviews and Notices of Books.

An American Text-book of the Theory and Practice of Medicine. Edited by William Pepper, M.D., LL.D., etc. Vol. II., p. 1046. Philadelphia: W. B. Saunders & Co. 1894.

The first volume of this treatise appeared about one year ago, and was noticed in these columns. An examination of the present volume shows that the excellencies of its predecessor have been well maintained. Dr. Welch writes on bacteria, infection, and immunity. Dr. Lyman on diathetic diseases, the acid dyscrasia, osteomalacia, obesity, biliary lithiasis, gravel, diabetes, polyuria, rheumatoid arthritis, gout, and rheumatism. Dr. Osler upon the blood, adrenals, and ductless glands. Dr. Pepper on the heart and large vessels and the mediastinum, mouth, tongue, salivary glands, pharynx and tonsils, œsophagus, stomach, and intestines. Dr. J. C. Wilson on the nose, larynx, bronchi, and pleuræ. Dr. Delafield on the lungs and kidneys. Dr. J. W. Holland on urinalysis; and Dr. Fitz closes the volume with chapters on the peritoneum, liver, and pancreas.

A work of this nature is essentially a series of monographs systematically arranged. Such an arrangement has both good and bad features. It is a middle ground between a mere student's text-book and an elaborate system. American physicians can, however, look with pride upon the work of Dr. Pepper and his corps of associates. It brings our knowledge down to the present hour, and has been written from an eminently practical standpoint.

The National Dispensatory. Containing the natural history, chemistry, pharmacy, actions, and uses of medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. By Alfred Stillé, M.D., LL.D., Professor Emeritus of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania; John M. Maisch, Ph.M., Phar.D., late Professor of Materia Medica and Botany in Philadelphia Coll. of Pharm., Secretary to the Amer. Pharm. Assoc.; Charles Caspari, Jr., Ph.G., Professor of Pharmacy in the Maryland College of Pharmacy, Baltimore; and Henry C. C. Maisch, Ph.G., Ph.D. Fifth edition. 8vo, pp. 1903. Philadelphia: Lea Brothers & Co. 1894.

The fifth edition of this well-known work has been much enlarged and thoroughly revised in accordance with the seventh decennial revision of the United States Pharmacopœia. The careful examination of this large volume will strike the reader with surprise at the great number of new articles added, and the amount of useful and accurate information regarding their properties, methods of preparation, and therapeutical effects. In general arrangement the work naturally corresponds with that of previous editions, and is the one best calculated for reference and study, as, in the first place, the articles appear in alphabetical order; and, secondly, the therapeutical properties of the different drugs are likewise noted under an index of diseases, in each case affording ready means for consultation. Many of the older articles have been re-written, others which have become obsolete have been omitted, while the large number of new ones containing all the latest synthetic remedies and unofficinal remedies, compass the entire range of available information in the line of the work. Although the metric system naturally takes precedence, the old one of weights and measures is not ignored, as separate formulas for the latter have been added for convenient quantities of all official preparations. A number of very complete tables, together with all the official re agents and solutions for qualitative and quantitative tests, appear in the appendix. Another notable feature of usefulness is the introduction of a list of over four hundred formulas and molecular weights of chemical compounds.

Altogether this work maintains its previous high reputation for accuracy, practical usefulness, and encyclopædic scope, and is indispensable alike to the pharmacist and physician. Every druggist knows of it and uses it, and almost every physician properly consults it when desirous of settling all doubtful questions regarding the property, preparation, and uses of drugs.

An Illustrated Encyclopædic Medical Dictionary. Being a dictionary of the technical terms used by writers on medicine and the collateral sciences, in the Latin, English, French, and German languages. By Frank P. Foster, M.D., editor of the New York *Medical Journal*. Vol. IV. New York: D. Appleton & Co. 1894.

The fourth volume of this admirable dictionary, which commences with Minnequa Spring and ends with Zythum, completes the work. In noticing the preceding volumes we have given an idea of the range and completeness of the series, and we need say at this time that the last is by no means the least. If anything, the latter would appear to contain more words and references than any of the former ones. A supplement of extra words which have appeared since the work began has been added, as well as a comprehensive list of the chief initial and terminal parts of compound words, and a table of weights and measures. Altogether the work is the most complete, most practical, and consequently most useful, medical dictionary now extant. We congratulate Dr. Foster on the completion of his stupendous task, and wish him long life to enjoy the well-earned fruits of his labors.

Dissections Illustrated. A graphic hand-book for students of human anatomy. By C. Cordon Brodie, F.R.C.S., Senior Demonstrator of Anatomy, Middlesex Hospital Medical School, etc.; with plates drawn and lithographed by Percy Highley. In four parts. Parts I. and II. London and New York: Whittaker & Co.

These plates are designed after those of Ford and Ellis, so familiar to students of anatomy, but are made smaller in size and less expensive in price, in order to adapt them to means and needs of a wider circle of patrons. Part I. comprises dissections of the upper limb, with seventeen colored plates, one-third life size, and Part II. contains twenty similarly made illustrations of the lower limb. The selections of divisions of regions are judiciously made, the anatomical parts are accurately represented in every necessary detail, and are admirably suited to the purpose of guiding the student in his dissections, and of refreshing the memory of the operating surgeon who finds it impossible to obtain material for rehearsal. The best study is the dead body itself, but the next best is a well-drawn and accurate anatomical plate.

Annual Reports of the State Board of Health of New York. One vol., 1892, and two vols., 1893. Albany: James B. Lyon, State printer.

These volumes represent the doings of the State Board during the years 1891 and 1892, and comprise reports of sanitary investigations of different parts of the State, maps of water-supply, drainage, etc., with a summary of vital statistics of different cities and towns, the average birth- and death-rates, and accounts of epidemics, notably that of influenza.

Sewage Disposal in the United States. By George W. Rafter, M. Am. Soc. of C. E., and M. N. Baker, Ph.B., Associate Editor *Engineering News*. 8vo, pp. 598. New York: D. Van Nostrand Co. London: Sampson, Low, Marston & Co. 1894.

The main purpose of this work is the study of American methods of sewage disposal, and their varied adaptability to different localities. It is fair to say that sufficient experience has been gained in regard to these points to

warrant the writing of a separate treatise. The manner of pollution of water-supplies, the varying degrees of contamination, the diseases arising from the same, and the different methods of sewage disposal, by filtration, precipitation, and irrigation, are exhaustively treated, based as they are on actual experiences in different cities throughout the United States. The self purification of contaminated running water is intelligently discussed, from chemical and biological standpoints, and many interesting data in connection therewith are intelligently and interestingly presented. The work will prove of great value to health authorities, sanitary engineers, and all others interested in the vital questions bearing upon this most important department of public health, and will become a standard authority in its line.

Philadelphia Hospital Reports. Vol. II., 1893. Edited by Charles K. Mills, M.D., Member of Neurological Staff. and James W. Walk, A.M., M.D., one of the Directors of Charities and Corrections. Philadelphia: J. B. Lippincott Co. 1893.

Although this volume has less than three hundred pages, it contains more variety of valuable medical and surgical material than most books thrice the size. There are over forty papers on as many distinct subjects, and all are practical and good. A fine steel portrait of the late Dr. D. Hayes Agnew adorns the work as a frontispiece.

Chart of the Officinal Chemical Salts of the U. S. P., 1890. Showing the Methods of Production, together with a Schedule of Neutral Principles and Phenols. By James Kennedy, University of Texas. 1894.

This is a large chart which may be hung on the wall. It presents at a glance a large amount of information concerning the chemistry of the officinal alkaloids and other remedies in common use.

Suicide and Insanity: a Physiological and Sociological Study. By S. A. K. Strahan, M.D., Barrister-at-Law; Member of the Medico-Psychological Association of Great Britain and Ireland, etc. Pp. xiv., 228. London: Swan, Sonnenschein & Co. 1883.

The subject treated of in Dr. Strahan's excellent little work has always possessed and, in the nature of things, must in future possess, keen interest not only for physicians and jurists, moralists, and sociologists, but for all thinking persons. That such a fundamental instinct as the desire to live should ever so far yield, either to reason or imperative craving, as to culminate in self-destruction, is a phenomenon so opposed to the principles of animal existence as to affect even the most unimaginative very much as would the sudden reversal of the law of gravitation.

Self-destroyers naturally fall into two classes: those who are impelled to suicide by ratiocinative motives, and those who arrive at the same sad climax, borne on the tide of imperative impulse. As may readily be supposed, these two classes are not by any means always sharply defined, but are separated by a large category of cases which are strictly neither rational nor impulsive, but partake in varying degrees of both.

Heredity naturally plays an enormous rôle in a suicide. This point alone has given rise to a voluminous medico-legal literature, and has been well brought out in the present work by convincing statistics.

The relation of suicide to race, climate, religion, occupation, and the season of year, have also been well shown. The author's arguments and resultant conclusions, which are the outgrowth of the question: "Is suicide justifiable under any circumstances?" are interesting, and in some respects startling. His final summary is worth quoting. "We are driven," he says, "from the foregoing examination to the conclusion that, although suicide may in some instances be criminal, as may any other human act, yet it is not necessarily so in all cases; or, as Dr. Donne quaintly puts it, 'Self-homicide is not so naturally sin that it may never be otherwise.'"

The book is well made and is provided with an index of sufficient scope to be helpful.

The Nurse's Dictionary. By Honnor Morten. The Scientific Press. London. 1894.

This is a pocket manual of one hundred and forty pages. It gives in clear, concise English, definitions of all the terms used in the literature of nursing. It is a useful guide for all novitiates in this art.

On Gout. By Willoughby Francis Wade, F.R.C.S., etc. Pp. 59. London: Simpkin, Marshall, Hamilton, Kent & Co. 1893.

In this essay the author endeavors to prove that gout is a peripheral neurosis. He finds evidence of the truth of this theory in the peculiar distribution of nerve-fibres about the great toe-joint. To the symmetrical distribution of gouty pains he also attaches much importance. Incidentally, the various theories of the malady are discussed in such a way as to show that the author has looked at truth from all sides. There will be differences of opinion as to whether Mr. Wade has proved his point, but none at all as to the reasonableness with which he has expressed his views.

Braithwaithe's Retrospect, Vol. CVIII., July–December, 1893. London: Simpkin, Marshall & Co. 1894.

The reputation of this well-known serial is kept up in the present issue. It covers, however, too small a portion of the field of medical literature to be very comprehensive.

Essentials of Practice of Medicine. By Henry Morris, M.D. Third edition. Philadelphia: W. B. Saunders. 1894.

This work, which has an appendix on urinalysis by Dr. Lawrence Wolf, comprises numbers eight and nine of Saunders's question compends. This series has already been favorably noticed by us.

Lectures on the Surgical Disorders of the Urinary Organs. By Reginald Harrison, F.R.C.S., Member of the Council and lately one of the Hunterian Professors of Pathology and Surgery, Royal College of Surgeons of England; formerly Surgeon Liverpool Royal Infirmary, etc. Fourth Edition. 8vo, pp. 588. London: J. & A. Churchill. 1893.

This well-known work in its present edition has been so thoroughly revised and amended that it has virtually taken a fresh start in its bid for continued popularity. From the first edition it stamped itself as authoritative in character, and its successive issues expanded its usefulness and practical work by the rapidly enlarging experience of its skilled author. In the form of lectures the general subjects are presented in an attractive and intelligible form, making easy and profitable reading, at the same time giving the book a practical turn which it could not otherwise, at least in a natural manner, so easily take. It is unnecessary to say that it is filled with practical and common-sense suggestions from one who in every variety of disease within the scope of his speciality has had exceptional opportunities for large experience. Many new and striking illustrations are added, and the work as a whole is further enriched by the incorporation of the author's Lettsomian Lectures (of 1888), as well as those delivered before the Royal College of Surgeons in 1891, the latter of which has not heretofore been published. As a whole it may be considered a standard book, written by one who is acknowledged as a leader in his line of work, and whose practices are eminently sound and whose principles of action are founded on the broadest possible basis of a large, varied, and successful experience.

Fissure of the Anus in Babes.—Dr. Daniel Martine, of St. Joseph, Mo. (*Clinique*), says that fissura in ano is common in infants, and usually escapes notice as the symptoms generally point to the bladder.

Clinical Department.

THE TREATMENT OF COUGH BY MANIPULATION.

By ORRICK METCALFE, M.D.,

NATCHEZ, MISS.

In 1868, in handling a wrist stiffened and somewhat enlarged and painful, I observed that the manipulation reduced the swelling perceptibly, and relieved the pain to a certain extent. On the following day there was less swelling and less pain. I inferred that by manipulation I might relieve pain from other causes than rheumatism. This was an inference, and I was impatient to test the correctness. It was not long before I was called to see a patient with a severe and painful cough. Somehow or other the idea occurred to me that the muscles might be more to blame for the cough than the lungs. The pain, in the case referred to, was at the edge of the ribs, to the right of the ensiform cartilage. On exposing the chest and abdomen I was surprised and delighted to find the first and second segments of the rectus abdominis of right side strikingly developed—such not being the case on left side These segments were painful. Manipulation of these parts relieved the pain very much, and enabled the patient to cough and expectorate more freely. In thinking over this case, and some others seen soon afterward, I was forced to the conclusion that possibly some pulmonary troubles were due more frequently to the muscles than to the lung itself. I asked myself where does the force reside that does the work in respiration? The answer was that the muscles do the work and the lung does only what it is made to do or allowed to do. The expansion of the chest allows the air to enter the lungs under atmospheric pressure, and the contraction of the muscles forces the lung to contract, and if there is any loose mucus in the bronchial tubes it may be expelled. It was not long before I came to the conclusion that in most troubles of the chest—consumption, pneumonia, bronchitis, and asthma—it is the external, not the internal, man that is sick. Twenty-five years of laborious observation, made under great difficulties, seem to me to have established the truth of the above proposition so firmly that I feel justified in communicating my views to the profession. I have overcome some of the difficulties, but there remains much to be done. I have reached a point where I do not dread, as formerly, to encounter a case of pneumonia, nor does a hacking cough in a consumptive patient alarm me. An asthmatic struggling for breath, and the patient with bronchitis that keeps one awake all night, do not deter me from promising relief in half an hour, so that the former can lie down to rest and the latter pass the day and night without any distressing cough. I could cite many cases confirming the above statement—more than fifty cases of pneumonia, a good many cases of consumption, and a great many cases of bronchitis and asthma.

The treatment by manipulation has an advantage over every other method with which I am acquainted in its prompt relief, but it sometimes enables one to be sure of his diagnosis at once, instead of waiting for developments. You not only find out what is the matter when you enable the patient to expectorate, but you afford him relief at the same time. In some cases there is no return of the pain. This all takes place in a few minutes—sometimes five, sometimes ten minutes, and sometimes a little longer. The last case I had was that of a young man, in good health, who was seized with a pain in the left side near the nipple, accompanied by a hard chill, at 10.30 A.M. At half past two he came to my office in great distress; temperature, 103° F.; pulse, 125. The pain in the side was so great that he could not cough, and consequently he had not expectorated. There was appreciable dulness over left lower posterior portion, and absence of râles of any kind. The pain on manipulation wa intense, but he was sufficiently relieved to be able to cough and expectorate a little. It was then possible to get the crepitant râle very distinctly. After the expulsion of the mucus with each cough, you could fully realize how much better the air enters the lung. As he was suffering from a severe headache, I gave him three grains of antifebrine. I saw him again at 10 P.M., and repeated the manipulation. The next morning I found him much better. He had expectorated the pathognomonic sputum of pneumonia. His fever was gone. I saw him twice more, manipulating each time. In forty-eight hours after I first saw him he was ready to go out on the street, and did go. This is not an isolated case. The profession may think it bold to rely exclusively on manipulation in a disease so often fatal. Believing that the essence of the disease is the disturbance of the relation between the muscles and the mucous membrane of the bronchial tubes, I have come to the conclusion that the disturbance is more quickly relieved by manipulation than by any other means. This was forced on me in a somewhat singular way, by accident so to speak, as many things are. Having been in the habit of prescribing iodide of potassium in ten-grain doses every three hours, I concluded more than two years ago to combine manipulation with the iodide, which I prescribed in the doses stated. It was a bad case apparently, if one judges by the distress the patient had been in for a week and the extent of the lung involved. The manipulation enabled him to expectorate, after which he could lie any way and rise in bed, whereas he had been forced to lie on his back. The next day, when I asked him how the medicine agreed with him, he told me that he had not bought it, and consequently had taken nothing. He was much better in every way. Of course, I was angry, and prescribed the potash again, and threatened to have nothing more to do with him if he did not get the medicine. The following day I found him much better, and again asked him how the medicine agreed with him. I always ask this question, because the iodide in such doses often distresses so as to force a discontinuance. To my delight, this time, he told me again that he had not got it. The manipulation, then, or coincidence, had the whole credit; naturally I gave the credit to manipulation. The next day when I knocked on the door he got up and opened it himself. That was my last visit; he was well. Soon after this I was sent for to see a young man living five miles in the country. Finding he had pneumonia I manipulated, and enabled him to expectorate, which almost always brings relief. I prescribed a solution of iodide of potash, eight grains to one drachm, every three hours. When I returned to see him, two days afterward, I found him better, and asked him how the medicine agreed with him and how he had taken it. He, by some accident, thought I told him to put a teaspoonful in a pint of water, and take ten drops of that three times a day. Here was another time that I gave the credit to manipulation, and not to coincidence, for I must frankly own that I do not believe the small quantity of the iodide had anything to do with it. Ten drops of a solution of eight grains to a pint, given three times a day, I do not think would exert much influence. It did not distress the patient in the least. My last visit to this patient was on Sunday. Two miles beyond was a woman, who had come to see me at my office in Natchez at twelve o'clock on the preceding Friday. Hers was apparently such a severe attack that I kept her in my office till five o'clock, so as to manipulate her twice. She had been ill several days, the fever was high—105° F.—and a large portion of the left lung was involved. She had seven miles to ride in an open buggy to reach her home. It was so cold that I had to give her a blanket to wrap up in. She left with instructions to let me know early the next morning how she was, and how the medicine agreed with her; true to her promise, she sent me word the next morning that the medicine had done her no good, and that she had coughed all night. When asked how he knew the medicine had done her no good, the messenger, her son, told me that he had broken the vial on the way home.

I was glad to hear that she had coughed all night, for I know no way half so good to free the lungs of the obstructing mucus. I was busy with another patient, and the son left, as good luck would have it, without my renewing the prescription. Being within two miles of her home on the Sunday mentioned, I concluded to make the ride of two miles to see what she was doing. I found her sitting up in bed combing her hair. On examination I found her condition much improved. I manipulated again, and not wishing to appear to neglect her I put a teaspoonful of the solution (used by the young man with such good result) in a pint of water, of which she was to take ten drops three times a day. She had no further trouble. A few days after this I was sent for to see a man who had been several days ill, and all that the messenger could tell me was that he had a mighty bad pain in his side. I had declined to go, but thinking it might be a case of pneumonia, I reconsidered and went to see him. It was a case of pneumonia, with high fever and severe pain, which caused great distress whenever he attempted to move. Manipulation soon relieved him so that he could cough and expectorate freely. I never saw him again till he called at my office, a year afterward, and told me that he hadn't had a bit of trouble after I put my hands on him. My hands would not have done any good had I not put them in the right place. By that I mean that the manipulation must be done in the right place, and may be in the right way. I could cite many cases of pneumonia treated by manipulation, some old people upward of eighty years of age, and young children, who are equally amenable to this mode of treatment. Sometimes the manipulation of the painful spot will be all that is necessary, in other cases you have to search diligently for the spot related to the lung involved, for there may be no complaint of pain till the spot is touched. Knowing that bronchitis sometimes runs into pneumonia, and sometimes into consumption, and that pneumonia runs into consumption, and that bronchitis runs into asthma, and asthma into consumption, I am inclined to think that they are (in many cases) phases of the same trouble, the trouble being a disturbance of the relation which, in health, exists between the muscles engaged in respiration and the mucous membrane of the bronchial tubes. I do not pretend to understand how the manipulation relieves this disordered condition, but that it does relieve it there is no doubt whatever. I have seen too many cases to have any doubt myself, and I have convinced my friends who had doubts about the possibility of what I claimed to be able to do. The results are so surprisingly prompt, and follow so certainly, that it is hard for one who has never witnessed it to believe it. Sometimes one manipulation will relieve a case of pneumonia where the fever may be high—105° F.—and the pain in the side severe. The relief may be so great that there will be no further anxiety on the part of the physician, and in some cases no further necessity for treatment. This seems almost incredible, but it is true. What I was taught and thought positive proof of pleuritic complication I have learned to regard as muscular pain. This position seems to me to be established by the disappearance of the pain as soon as the relief afforded by the manipulation allows the patient to expectorate the characteristic sputum of pneumonia. Anyone who has studied pneumonia in its early stage has observed occasionally cases where the sound caused by the passage of the air through the mucus resembles the friction-sound so closely that you could only be convinced as to the nature of the sound when the mucus is expelled and the sound is no longer heard nor the vibration felt.

The method of manipulation is as simple as it is effective. Continuous and firm pressure is made upon the painful part of the chest by the tips of the fingers, the latter being at the same time made to move the skin in a circular direction within the area of pressure. At first the patient will complain of increase of pain, but I tell him to cough, when, after some minutes, expectoration occurs and then the pain disappears. But I generally persevere, even if it takes ten minutes or longer, until expectoration takes place. The longer I pursue this study, and the more extensive my observation becomes, the more I am inclined to hold to the notion that it is the external and not the internal man that is sick at the start in many cases of pulmonary trouble. The ideas expressed have seemed new to most of the professional men to whom I have explained them, and I hope I am not mistaken in thinking them worthy of publication. To some they will seem extravagant and absurd, but I hope that they will receive that respectful consideration which honest work always deserves. All I ask of my readers is that they follow the advice of that great thinker, Lord Bacon, who says you must read "not to contradict nor to believe, but to weigh and consider."

A CASE OF ANEURISM AT THE TRANSVERSE PART OF THE ARCH OF THE AORTA.

By A. HYMANSON, M.D.,
NEW YORK.

Joshua Z——, a pedler, aged thirty-five, born in Russia, eight months in the United States. No history of syphilis or rheumatism in the family. Father died of phthisis at the age of forty.

Previous history: Patient served in the Russian army from the age of twenty-one up to twenty six. Until the age of thirty-three he had an easy position as clerk in a store in St. Petersburg. Led a quiet and temperate life; was never exposed to hardships. Had always enjoyed good health, except in 1881, when he was sick with a gonorrhœa for about seven weeks. Married, has two children in good health.

History of the present attack: About three and a half years ago there was a conflagration in his store; he was exposed to cold, and carried some heavy weights. Two weeks later he noticed pain in the right shoulder and upper extremity, and right hemicrania; had also some pain in the left forearm and hand; which he thought was rheumatism, and applied liniments. A month later he noticed a small tumor throbbing in the suprasternal notch, which increased gradually. He soon was subject to cardiac palpitation and shortness of breath on excessive exertion. The hemicrania and the pain in the right upper extremity induced him to seek for medical advice; different plans of treatment have been tried; he received also strophanthus (?) without the slightest effect. To a physician in Libau he owes thanks, as to the only man who was able to relieve his suffering, for about six months, by the use of hypodermatic injections of morphia several times in a day. During the following year the patient practised the same treatment on himself by obtaining a needle and injecting two or three grains of morphia daily. On exertion, when the tumor was increasing in size and palpitating strongly, he applied ice or cold-water compresses, which relieved him wonderfully. He felt so comfortable that he could attend to his ordinary avocations.

For about six months, since he came to this country, he was exposed to hard labor (he was peddling fruit with a push cart), and experienced great inconvenience on the slightest exertion—shortness of breath and cardiac palpitation—and for the last two months he has been obliged to give up his work entirely.

Patient has a harsh metallic cough, without expectoration, and stridulous breathing when he lies flat on his back. On examination a pulsating tumor, as large as a man's fist, is found at the suprasternal notch. On auscultation an accentuated booming sound is heard all over the tumor; there is a double murmur to be heard at the aortic valves, and a faint double mitral murmur at the apex. Heart is somewhat hypertrophied, and displaced to the left and downward. Loud tracheal breathing; respiratory murmur feeble, and more distinct on the left than on the right side. The radials on both sides equal. There is no impairment of vision, pupils normal, no difficulty in swallowing. The face flushed on excitement, on both sides equally. When at rest there is no pain at the site of

tumor. The urine acid in reaction had a specific gravity of 1.012, it contained no albumin.

The points of interest in this case are, first, its vague etiology; the man had no syphilis, no gout, nor was he exposed to very heavy labor; there must be some degenerative changes in some parts of his arterial walls. Secondly, the duration of the disease. According to the opinion of Dr. Garland[1] the progress of aneurism of the aorta is very rapid, and in the majority of cases the fatal termination is not delayed many months. Out of 40 cases 20 died within one year, 9 lived for two years, and 3 lingered five years; here is a man who worked hard for six months in the fourth year of the disease. Thirdly, and the most interesting point, is the use of such large doses of morphia for more than eighteen months. Professor A. L. Loomis, at his clinic in the University Medical College, expressed himself about this case that the use of morphia actually prolonged his life; it not only relieved his pain, but by its quieting and regulating influence on the heart it delayed the growth of the aneurism.

To Dr. E. Le Fevre I express my thanks for his kindness in examining the patient with me.

AN UNUSUAL OBSTETRICAL EXPERIENCE.

By CLARENCE W. GOSS, M.D.,

LANCASTER, O.

On January 21, 1893, at noon, I was hurriedly summoned to see Mrs. T——, who was suffering from severe pain in the head. Upon my arrival I found a woman, about twenty years of age, with luxurious surroundings, a primipara, who was in the last month of her pregnancy. She had engaged my father, Dr. J. H. Goss, three months previously, to attend her, but did not expect confinement for a month yet. I administered a quarter of a grain of morphiæ, hypodermically, which quieted her in a few minutes, and left. Six hours later my father received a telephone message from her husband to come up immediately, that his wife was having a convulsion. This he did and I followed a short time afterward. Upon my arrival I found her coming out of the third convulsion and rapidly succumbing to the influence of chloroform. The chloroform was pushed until there was complete relaxation, the forceps were applied high up, and after forty-five minutes' powerful physical exertion upon the part of my father and myself, a ten pound boy was born, the placenta coming immediately afterward. The child was cyanotic, and there was a complete absence of any signs of life. The chloroform was still administered to the mother at intervals, and in the meantime sixty grains potassii bromide per orem, and a half-grain of morphiæ, hypodermically.

At this time the child that was thought to be dead came to my mind, and I resolved to try artificial respiration, with no thought of accomplishing anything. I alternated between the Schultz and Goodell methods, and after a half-hour's unceasing work, signs of returning life were discernible. The color of the body's surface became better, and an occasional spasmodic attempt at respiration was manifest. After another half-hour's tiresome work, I had the satisfaction of hearing a lusty yell and seeing a bright red body-surface. Up to this time the mother had been quiet, and the chloroform was discontinued. Suddenly, without any apparent warning, the pulse jumped from 80 to 170 per minute, full and bounding, and a most fearful convulsion came on. So rigid were the jaws that a wooden plug, which had been put between the teeth in the other convulsions, was bitten nearly through. A ligature was hurriedly thrown around the arm, above the elbow, and a lancet plunged into the median cephalic vein. In about fifteen minutes the pulse dropped from 170 to 90 per minute, and the patient relaxed once more. The amount of blood drawn was nearly three pints. At this time Dr. G. W. Boerstler was called in consultation, who kindly responded and found the patient resting quietly. It was deemed advisable to give tinct. verat. viride, in fifteen-drop doses, as needed, which readily kept the pulse about sixty to the minute. By four o'clock next morning the patient was conscious, and from that time on made an uninterrupted recovery. Up to this time the child, not being satisfied with his previous narrow escape, took on tetanus neanotorum. He was put on his left side and five-grain doses of potassii bromide, every three hours, were administered per rectum. At the end of five days he recovered, and six weeks after he was a bright hearty baby.

The above case is, I think, somewhat unusual, and it demonstrates to my mind what can be accomplished by perseverance and artificial respiration. It is also an earnest plea to the practitioner not to abandon hope too soon. This is often done, as in my own case, when a chance thought directed my attention to the baby, and thereby a human life was saved.

NINE DRACHMS OF BROMIDE AT A DOSE.

By MARIA M. VINTON, M.D.,

NEW YORK.

March 5, 1894, A. V——, aged thirty, superintendent. The patient is not a strong woman, but very energetic. She has a marked murmur of mitral regurgitation, which has existed for several years, and on over-exertion has palpitation and shortness of breath.

About 7.30 A.M., desiring to take a dose of Hunyadi water, she went to the closet for a quart bottle, poured out about half a tumblerful, and drank it off. Noticing that it seemed unusually salty, she went to examine the bottle and found on one side a small label stating that the bottle contained a solution of potassium bromide, gr. xx. to ʒ j. At first she was much frightened, but having considerable knowledge of drugs, and realizing that potassium bromide is not a dangerous poison, she went on with her dressing, and by the time she was ready for breakfast she sent for me to know what she had better do. As I was not prepared for the day's work, I sent word to her to take ℥ ss. of whiskey, on account of her weak heart, and a cup of strong coffee. I did not order an emetic, believing that the solution taken some time before on an empty stomach had passed into the intestine. About fifteen minutes later I saw her just coming from breakfast and feeling no effects from her dose. Her pulse was as good as usual, and normal in quickness. We measured the quantity of bromide which she had taken in a peculiarly marked tumbler, and found that it amounted to about ℥ iijss., thus containing ʒ ix. or gr. 560 of pure bromide. I gave her a hypodermic of strychnia, gr. 40, and ordered more coffee later.

At 10 A.M. she felt as well as usual, rather light-hearted, and sat down to her desk, where she wrote for about four hours. The afternoon was spent out-of-doors on business. She occasionally felt drowsy and once fell asleep in a train. She took more coffee at night and attended the theatre, after which she went to bed and slept well.

March 6th.—She felt depressed, gastric and intestinal digestion were poor, and bowels torpid, and her head felt heavy, with times of drowsiness. At night she took a dose of Rochelle salt, which kept her up and down all night and she slept very little. She had taken strych. sulph., gr. $\frac{1}{30}$, t.i.d.

March 7th.—She felt much better and was at work as usual, and the following day felt as well as usual.

It is interesting to note that this drug, which is taken so freely by epileptics after establishing a tolerance, can also be taken in so large a single dose without any more marked symptoms of depression. In all probability not nearly all of the bromide was absorbed on account of the depression of the digestive functions caused by it.

OUR LONDON LETTER.

(From Our Special Correspondent.)

CHELSEA HOSPITAL FOR WOMEN—THE MANAGEMENT REPLY AND DEMAND INQUIRY—STATEMENT OF THE STAFF—THE OFFICERS OF HEALTH TO GIVE FURTHER REPORT—SCHOOL OPHTHALMIA—SYMPHYSEOTOMY, A PAPER BY AN AMERICAN AUTHOR—CEREBRAL SURGERY AT THE CLINICAL SOCIETY.

London, March 17, 1894.

The authorities of the Chelsea Hospital for Women have lost no time in replying to the charges made by the Medical Officer of Health (Dr. Louis Parkes), and which I have previously reported. It will be remembered that the report of Dr. Parkes was considered so serious by the vestry that they sent copies to the Home Office, and the Local Government Board, and requested an official inquiry. This inquiry was not granted and the treasurer of the hospital has sent to the journals his statement of the facts, which certainly differs essentially from that of Dr. Parkes, who, he declares, asked for power to close the hospital, "which he well knew had been shut for five weeks, and in which he knew public money was being expended to carry out, loyally, every recommendation, reasonable or otherwise, which it had seemed good to him to make." The treasurer adds that the Board of Management are making representation of the facts to the Home Secretary and President of the Local Board. This is certainly a fair retort to the vestry, and the best course that could be adopted, for the reflections made by Dr. Parkes were such that some step of the kind was necessary. Another point in his report was that an authoritative official statement as to the operations, mortality, causes of death, etc., ought to be made. The challenge thus made has been promptly accepted by the medical staff, who have issued a bulky pamphlet giving these particulars and many others. Dr. Parkes says he is preparing a report in reply to this, so it is too soon to express a definite opinion as to all the matters involved. It is only fair, however, to acknowledge that the mortality of the operations does not seem to be greater than at other institutions, and that the staff appear to state the medical facts with candor. If their statements and the assertions of the treasurer should be completely proved, Dr. Parkes will have the honor of having "discovered a mare's nest," and Medical Officers of Health will, perhaps, take the lesson to heart. Without at all forestalling results, I may remark that it is very questionable whether such officers have any *locus standi* for reporting on medical and surgical questions at hospitals. Presumably, the staff are much better judges, and compared with them the officer of health must be ignorant of such questions. In sanitary matters they may be glad of his advice, though on medical or surgical questions they would be justified in considering it impertinent. *Ne sutor ultra crepidam* is a proverb that needs impressing on many officers of health. This fact has been made more obvious lately in various localities, and many complaints have been made by practitioners as to the manner in which these officers interfere in notification cases and other matters.

At the adjourned discussion on School Ophthalmia, Mr. Hutchinson declared he had understated the frequency and severity of the cases rather than exaggerated them. In the school on which he had been consulted all the boys had been sent home for two months, but the affected ones returned worse than when they left. As to the suggestion that there were two forms of the disease, one mild the other severe, it was for those who thought so to prove it. He could find no evidence of it, and insisted on treatment at the earliest stage. Several members stated that they had observed a great increase of ophthalmia during the past year. Disbelief was expressed in two forms of school ophthalmia and defective sanitation was generally blamed, while it was urged that the utmost precautions should be enforced whenever an outbreak occurred.

The Obstetrical Society has had a paper on symphyseotomy by Dr. Robert P. Harris, of Philadelphia, based upon its record for the last eight years. The operation has not found much favor in England, and some of the reasons for this were well brought out in the discussion, such as the mortality being as high as that of Cæsarean section; the ease of combining the latter with sterilization, the unsatisfactory after condition so far as reported, and doubts whether union would occur after repeated operations.

The difficulties of cerebral surgery are well illustrated in the case of a lad of fourteen who went as an out-patient to the London Hospital complaining of intense headache due to a blow upon the right mastoid region some weeks before. An abscess was found and opened (superficial to the periosteum) with relief. A week later the boy returned with the same symptoms in an aggravated form and was admitted. The abscess, which had closed up, was reopened, and the periosteum incised, again with relief. Five days later the pain reappeared, with drowsiness, restlessness, and other signs of cerebral pressure. The mastoid antrum was trephined and examined, but nothing was found inside it. It was not washed out, as there was no disease of the ear. After this the boy appeared perfectly well for ten days; then all the symptoms returned in an aggravated form, with optic neuritis in addition on the right side. The skull was trephined over the temporo-sphenoidal lobe; no pulsation was detected; the dura was healthy, but bulged upward, into the wound. A trocar and cannula were inserted in various directions without result. The bone was then removed from over the cerebellum and an exploration carried out there with equal want of success. Finally, a few drachms of fluid were drawn off from the descending corner of the lateral ventricle through the temporo-sphenoidal lobe, and pulsation returned. Twenty-four hours after the patient died comatose. At the post-mortem there was no middle-ear disease or inflammation upon the right side of the head or brain. In the left temporo-sphenoidal lobe was a very old encysted abscess, with some cohesions to the dura mater over it. Nothing else was found. The case was related at the Clinical Society on the 9th inst, by Mr. Mansell Moullin, who also mentioned another in which he had explored without finding pus, yet three weeks later, after death, they found an abscess occupying almost the whole of one cerebral hemisphere.

Mr. Clutton pointed out that the trocar was not of much use in exploring for pus in the brain, and he mentioned a case in which careful exploration had failed to reveal pus, yet after death abscesses were found in the temporo-sphenoidal lobe and in the cerebellum. At the same meeting Mr. Battle read notes of three cases of extra-dural hemorrhage which had been operated on by him during the past few months.

Case I.—A woman, aged fifty-nine, with compound depressed fracture of the skull and compound comminuted fracture of the os calcis and astragalus. Temperature, 95.4° F. There was some oozing from the fracture of skull, but nothing to indicate hemorrhage, excepting marked shock. No paralysis or even inequality of pupil. Operation was done for the depressed fracture, and a large clot found which had compressed the right hemisphere to such an extent that no expansion followed its removal, and she returned to bed, with a large depression of the right side of the brain. The shock gradually passed off and no symptoms of unfavorable return developed. The leg was saved, although some sloughing of the wound followed, this was not accompanied by suppuration, and she left after a residence of thirty-five days. She is now able to walk, wearing a head and side iron.

Case II.—A boy, aged five, operated on two hours after the accident, a fall on the head from a coster's barrow. There had been no interval of consciousness. There was

a baggy, bloody swelling in the scalp extending from the temporal region upward and backward toward the longitudinal sinus, marking the site of a simple fissured fracture of the skull. He was quite motionless, and could not be roused, pupils equal and reacting to light. Then twitchings developed in the eyebrows, left ala nasi, left side of the mouth, afterward in the left arm and leg. There was some twitching in the right side, but less marked. The pulse was full and slow at the time of the operation, right pupil the larger, but acting to light. No conjunctival reflex, no response on pricking with a pin. The diagnosis was fissured fracture of vault with extra-dural hemorrhage. Operation was done by semi-lunar flap, insertion of blade of Hoffman's forceps in fissure, the edges of which were separated at head by one-eighth of an inch, removal of sufficient bone, and application of ligation of silk to wounded vessel (anterior branch of the middle meningeal artery) by means of needle passed through the dura-mater round it. The anterior end of the fracture ran forward into the orbit. Recovery was perfect.

Case III.—Was that of a robust man who fell from a scaffold. There was a fissured and slightly depressed fracture in the right parietal region. No loss of consciousness. Drowsiness, unconsciousness, deepening into coma, with left hemiplegia and dilatation of the right pupil, a purple condition of the face, embarrassed respiration with much sweating developed. Operation was performed and a large clot of blood found. Much bleeding went on during the necessary manipulations. Bone was removed forward, and on failure to find the bleeding point the opening was extended backward. There was an opening in a large vein of the dura mater one-half inch from the superior longitudinal sinus, near the posterior-superior angle of the parietal. This was closed with a silk ligature passed by means of a curved needle. Another opening from the head from which venous blood flowed, no longer permitted escape after application of forceps. There was no expansion of the brain and the man died four hours later, not having recovered consciousness.

MORPHINE vs. PERMANGANATE OF POTASH.

To the Editor of the Medical Record.

Sir: In your esteemed journal of March 10, I have been rather severely criticised by Dr. Glenn Andrews, of Montgomery, Ala. While I feel happy that the use of permanganate of potassium as an antidote to morphine should be made the subject of investigations and discussions, yet I am unwilling to make anything but publications that appeared in scientific periodicals the basis of such discussions. Dr. Andrews is perfectly right in exclaiming: "According to the cases referred to by Dr. Moor the only death occurring was a rabbit given one grain of morphia through the mouth, and subsequently a gastric fistula was established. In my opinion if the doctor had discovered an antidote for the fistula instead of for morphia, his rabbit would not have died," but nevertheless Dr. Andrews will be amused to learn that the martyr rabbit in question died neither from morphine nor from a gastric fistula, but expired after a few sniffs of chloroform ere the knife had reached him. *Requiescat in pace.* There is another point, Mr. Editor, which requires rectification. In the Medical Record of February 24, 1894, you say that according to the *Journal de Pharmacie* of Alsace Lorraine, an Alsatian pharmacist, M. J. Anthal, has discovered by means of a series of experiments on dogs, rabbits, and frogs that permanganate of potash acts as an antidote to phosphorus, muscarine, strychnine, colchicine, oil of sabine, and oxalic acid. To convince myself of the correctness or erroneousness of such a claim I made the following tests:

1. To one grain of phosphorus under water (thirty minims) I added one drop of a 1 to 15 permanganate solution, which imparted to the thirty minims of water the characteristic purple color. This remained unaltered after one minute's vigorous shaking and showed no change after several hours' standing. Even after sixteen hours the original purple color had become only very slightly lighter. It is therefore evident that permanganate of potassium can have no effect on phosphorus in the presence of other organic matter.

2. One ounce of water at 98° F. was added to two grains of sulphate of strychnine in crystals. After thirty minutes the size of the crystals was still the same. Two grains of permanganate of potash in one ounce of water were added, producing first a purple solution, changing into carmine. Thirty minutes later the color was still carmine, the crystals of strychnine still remaining of the same size. Thus we see that the permanganate had practically no effect on strychnine crystals. To test the effect of the permanganate on a perfect solution of strychnine in the presence of albumin, I dissolved one grain of sulphate of strychnine in two drachms of boiling water, added to it, after the water had cooled off, one drachm of the white of an egg, stirred well, and then rapidly added, while stirring, one grain of permanganate in fifteen minims of water. Having filtered this mixture, I injected two drachms of it subcutaneously into a full-grown rabbit. In two minutes after the injection the animal was trembling, in five minutes he had tetanus, in thirteen minutes again tetanus ending in death. Another full-grown rabbit received only one drachm subcutaneously, resulting after two minutes in tetanus and three minutes after the injection, in death. Thus one grain of permanganate had no antidotal effect on one grain of strychnine in the presence of one drachm of albumin. In another instance I dissolved one grain of sulphate of strychnine in thirty minims of boiling water, added to it two drachms of the white of an egg and one drachm of water, and then two grains of permanganate of potassium in thirty minims of water. Having filtered, I injected one drachm of this solution into a full-grown rabbit at 8.32 A.M. In a few moments the rabbit became agitated, his respiration exceedingly rapid, eyes protruding. At 8.47 A.M. he received another injection of one drachm. At 8.55 his hind legs were stiff, at 8.58 he had tetanoid convulsions. At 9.13 he received a third injection resulting six minutes later in tetanus and death. Thus it is evident that permanganate of potassium has no antidotal effect on strychnine in the presence of albumin.

3. One drop of a 1 to 15 permanganate solution retains its purple color in a saturated solution of oxalic acid, four grains to one drachm of water, for thirty seconds, imparting at the same time its purple color to a part of the solution of oxalic acid. This is sufficient proof that albumin, peptone, etc., would deoxidize the permanganate of potassium, ere the latter could have any effect on oxalic acid.

4. Cases of poisoning by colchicine itself have not been recorded. As to the preparations of colchicum, one drop of a 1 to 250 permanganate solution remains purple for several seconds, and then turns red and stays so for one minute in a one per cent. solution of the acetic extract of colchicum. The reaction, therefore, between the latter and the permanganate is not rapid enough to be of any value in the presence of albuminoid bodies.

The aforesaid warrants the conclusion that if permanganate of potassium has been shown, by means of a series of experiments on animals, to act as an antidote to phosphorus, muscarine, strychnine, colchicine, oil of sabine, and oxalic acid, those animals experimented upon must have been in a condition ideal for such a purpose; *i.e.*, their stomachs must have been empty.

There is another point upon which I should like to dwell briefly. In my article, which appeared in the Record of February 17th, I said that ten or fifteen grains of the antidote, repeated three or four times, should be given in cases of opium poisoning. Having shown that a certain amount of morphine is decomposed by the same

quantity of permanganate of potassium, it is natural that whenever there is evidence or suspicion that more than fifteen grains of morphine or its equivalent of a preparation of opium have been taken, a corresponding amount of the antidote must be administered in order to prove efficacious.

William Moor, M.D.

355 Boulevard, New York.
March 20, 1894.

FIRST STUDY GERMAN AT HOME.

To the Editor of the Medical Record.

Sir: Referring to the article in the last edition of your paper, "German Literature a French Necessity," I wish to call your attention to a matter well worth considering. I do not intend to dwell on the study of the classics, nor can I understand why medical faculties again and again weigh the arguments for and against their study. We all know how much a knowledge of Latin has helped us in the pursuit of our work; the need of a universal medical language is to a degree met by the use of Latin, which has so long been the agent to express medical thoughts intended to travel, irrespective of zone and climate, to all parts of the world. We must, for these reasons, advocate the study of Latin, and more especially as, from the common origin of their tongues, English, French, Italian, and Spanish speaking people can so much more easily attain proficiency in Latin, than, for example, Germans. To know and understand English means to know Latin. I claim that an English student, properly and practically taught, can learn in two months all the Latin he will need to remove that sentiment of inferiority, and to maintain the dignity of the profession, for which reason the Medical Faculty of Paris advocate the study of Latin. With regard to the pronunciation, permit me to ask if it is not advisable to teach young men intending to enter the study of medicine, the Roman pronunciation? It would assist them greatly if they should desire to continue their studies in Germany.

Each additional language acquired affords to the speaker a new life, permitting him to receive from and impart to another nation new ideas, to compare old ones, and by comparison evolve new thoughts of value to our profession. To day, when medical science derives its elements from all parts of the world and international intercourse is on the increase, a physician almost imperatively must be a linguist. But languages are so numerous, and a physician's time so occupied by the advance of medical science that we must be content to master two, or even one foreign tongue. Naturally we would select the language of the land which is generally accepted as being the chief seat of medical learning. The French Medical Faculty has just and justly conceded supremacy to Germany, and advocates the study of German. Not colloquial, but medical German is wanted to enjoy the fruits of labor of the German savants.

At no time has the study of medicine received more attention in this country than at present. The fraternity rejoices to see the standard raised by State laws, and trusts both to the work of medical authors and to the wisdom of future law-giving bodies to establish and further advance the reputation of American medicine. It is the duty of each of us to be instrumental in this direction, and as we would resent an insult to the Stars and Stripes, so should we also defend our intellectual reputation, wherever it is carried. There is one thing tending to our hurt abroad—the rush of American physicians and medical students to Europe without previous training to receive the teachings of the European professors in their own language. The wide usefulness of your journal encourages me to seek here an opportunity to utter a warning word to those contemplating a continuance in Europe of their studies begun here.

Medical European tourists may be classified thus:

1. Those seeking to learn German alone by listening to medical lectures; 2. Those seeking to learn German and study medicine with no knowledge of German; 3. Those seeking to learn German and study medicine with a smattering of colloquial German.

The men of the first class are doing fairly well, but I would advise them not to spend so much time in the lecture-room, where, being only listeners, they neglect their tongue, and fail to receive the necessary practice and correction for successful study of language. The acquisition of a language is not a matter of intellect, since the child progresses better than the adult, but is one of memory and practice. Let the American student, then, mingle freely with educated Germans, and select from the German, not medical but philological students, a practical private teacher. I say practical, for it is astonishing how impractical some of them are. In this manner only can a foreigner gain fluency of speech and the spirit of the language. For our purpose it is the spirit of the language which we must imbibe if we would profitably read German medical literature. Only in this way will the student get an equivalent for his time and money.

The second and third class men, from the very perversity of their undertaking, must needs fail. They both lose their time and money. They gain nothing in medicine, but rather lose. They do not learn even as much German as the men of the first class, giving their full attention to the study of German only. While the second-class men seem more daring, they still injure none but themselves; the men of the third class, with their smattering of German, do a great harm to the American reputation. Say that two students, for example, of the second and third class, of equal perceptive powers, shall go abroad to study, suppose to Berlin. With a full pocketbook, and the best wishes of the community, each sets out. Already on arriving at the seat of a university, they have learned that with a little or no German at command it is only their money which is interpreter and provides for material necessities. Eager to go to work, after only a few days of rest, they seek the university. They accomplish much if they find a person who can direct them to the various and widely separated medical institutions belonging to the university. Having found the place sought, each presents his letter of introduction to the professor, say Rudolph Virchow. Nearly everyone has some such letter, of little or no avail to the bearer, though well meant by the home professor. Professor Virchow—wonderful man with wonderful memory—may or may not recollect the writer of the letter, but he will courteously invite the bearer to attend his lectures. A certain professor is reported as saying: The road to my lecture-room leads across the quaestor (who collects the fees). Thus, after all, it is not a letter but money which procures admission. The newcomers now must fight their own battle, and a hard one it is for both men. It requires pluck to bear up when it becomes evident one has travelled thousands of miles, spent hundreds of dollars, and even intrusted dear life to the treacherous ocean—to be unable to understand one word of the great professor. Trained as the native student is in the language, it requires weeks to learn the ways of the professor. How much longer will it require for a foreigner, even if he speak German. And how is it possible at all if he speak but little or none? Now our two students learn that they must abandon all or part of their original plan. Study medicine in German they cannot, study German in medicine they may and, in a measure unwisely, do. Thus they become of our first class, studying the German language at medical lectures. If these two men do not surrender their original plan, what is the result? They soon become acquainted with German students. The man with no German speaks not, and thus is harmless, receives the benefit of doubt, being silent, and is deemed the wiser. But the other, who has a German smattering, soon finds himself speaking on medical topics. He says what he does not mean and does not know what he has said. The German student, having never tasted a traveller's embarrassment, lacks charity. Thus comes misunderstanding. The American, as I have

seen, has become the laughing stock, and a poor opinion of American scholarship is formed by the German students. Our unfortunate student, then, is not, as good citizens should, maintaining the national reputation abroad. Having attempted to do two things at once, *a priori*, his sagacity is doubted, since a man of attainments knows better. However, our two travellers advance daily in German, the third-class man ahead of the other. Now if they mean to stay at least three years in the one place, devoting half of that period to language alone, then one semester to familiarize themselves with the ways of certain professors, with whom they intend to study, and finally the last year to careful note-taking, all would be well. But what are the facts? Americans stay rarely longer than one year, many only one semester. There is here an erroneous impression that sufficient German may be learned in three months to listen to medical lectures. Withal American travellers, despite of their good qualifications of application and thorough preparation in elementary medical branches, are an unsteady, restless class of students (possibly made so by their failure to accomplish what they unwisely undertook). They are eager to see many universities and hear many great professors. They become rolling stones gathering no moss. Returning home, they doubtless in a measure are fair German conversationalists, but no better clinicians than before. Many, doubtless, wish, that which policy forbids them to utter, that they had never left home without previous training in German.

But there is another very important matter. The time of stay abroad being limited and the desire to see many different universities so strong, these students cannot, as earnest workers should, settle down to imbibe knowledge from the fountain. Eagerness to improve increases as time remaining decreases. They notice daily progress. Finally they think they understand the lecturer fairly well. They take notes! In them the European professor is constantly misrepresented and the home professor unjustly criticised, while the student is at a loss what to believe. I have time and again seen and corrected such notes, and what an interesting mine of misinformation you see clothed in the skeleton of the professor's words, but conveying not even a fragmentary bone of his thoughts! Progress and not less egotism, only natural to mortals, establishes in these students a firm belief in their German knowledge, all the more so as they are by this time able to understand the words and even some sentence of minor importance of the professor. They forget that words are only agents to express or to hide thoughts. They are not yet far enough advanced to analyze the professor's long and sometimes tedious and intricate sentences, to unvail the deep thought contained therein. They also forget that a little seemingly insignificant word, without attracting a foreigner's attention, might modify or alter the meaning and importance of a thought. Let these two men now return after a year's absence to their community, which rejoiced at and commended at their going and again at their coming. They soon set up a lucrative practice on the strength and reputation of the "studies abroad;" but who can tell how many will suffer by the treatment founded on those unreliable notes? The doctor is thus unconsciously made to do harm where intention and duty prompt him to do good.

In view of these facts I have tried to induce some members of the Faculty of Berlin University to give courses in English. Some of them, for that purpose, joined a course of medical English which I held at the Royal Polyclinicium of Professors v. Bergmann and Schweigger, with the result that in the near future some English courses will be given. It is, however, not for them to give up research to become polyglots, but it is the duty of the foreigner to bring his tools to work with.

Now, Mr. Editor, I would urge the American necessity to study German and German literature, and more especially I would ask you to hold before your reader the imperative necessity to prepare before leaving home to understand the German professor, if to him they must go. It is for the benefit of those Americans and German descendants who shall go hereafter that these lines are written to spare them the disappointment, save them time and money and the impeachment of their sagacity.

Professor Rudolph Virchow, in his rectoral inaugural speech of 1892, commented favorably on the application of American students in Berlin. Let us in the future prepare so that men of his calibre may speak favorably of our success due to application and training.

J. C. Lewinsky, M.D.

1758 Madison Avenue, New York.

OPIUM AND ITS EXCESSIVE USE.

To the Editor of the Medical Record.

Sir: The use of morphine and other forms of opium is said to be on the increase. We are informed by the drug trade that the demand for opiates has increased materially in the last six or twelve months. It has occurred to me, as I have given the excessive use of opiates some thought, that it would not be out of place to make some suggestions on this subject. During the time mentioned there has sprung up a great interest, especially among the profession and others, on the subject of curing the opium habit, and a large number have undertaken to cure it, and are teaching people that the chief point to gain is to stop the use of opium without much reference to the damage done by opium when used for a long time in large quantities. There is a disposition to teach that the opium habit is a small matter of very easy remedy and susceptible to almost magical cure; and it is my impression that it is that idea getting hold of the people that is inclining them to use it more carelessly and excessively than they would otherwise. There is hardly any curse greater than the opium habit established in a family. I have often said that if you would give me an instrument which would represent to the fullest extent the idea of eternal punishment, I would take a human being and get him into the opium habit and then keep him from taking quite enough to satisfy the morbid craving. I think then we would have a condition that is as miserable for the body and soul, you might say, of the afflicted one, and as terrifying and tormenting for the time being, at least, to him and his relatives as Hades itself could present.

Now opium is a good medicine in its place. It is a good servant but a terrible task-master, and it is a well-established fact that its tendency is to increase its domination and general destructive influence over any people among whom it once gets started, and this is especially true of a nervous people, who live so fast, work so hard, and in every way put the nervous system on such tension as the people of this country do.

While opium is, as I have said, a good servant under certain conditions of acute pain, extreme irritability of the nervous system, etc., it is an exceedingly dangerous and destructive one when taken in large quantities for a long time. It locks up all the secretions, perverts all the functions, unbalances the mental faculties, and in every way prevents a man or woman from accomplishing the true designs of life. This is the latter or chronic effect it produces. Small doses making certain impressions, then larger ones being required to make a similar impression, and so on until the whole system is dominated by it. The teaching that this condition can be magically changed is entirely irrational, and the object of this article is to teach the people not to believe that simply stopping opium is curing the diseased condition produced by it. They will be led astray and thousands will carelessly use it and thus be carried on to destruction that would not be if they could realize the course of the habit and the difficulty of getting over the bad effects of it.

There is material enough to fill many pages of your journal that would be well enough for the public to know on this subject, but I do not feel inclined to encroach further. This is a mere hint. Not long since I saw in

your journal an article something like this, saying that if a person could use opium in moderation it would do the system no material harm—very likely do it good. This is very unwise teaching, in my judgment, or, at least, it is a matter that ought not to be placed before the public without further explanation of the difficulty of doing that. The opium habit is established from the very fact that, as a rule, you cannot use opium continuously in moderation. Every man who has given the subject any serious thought must come to this conclusion. It is a good thing when it is needed in acute diseases, and sometimes in certain kinds of chronic diseases that are hopeless in their nature, etc., and in many ways it is useful; but when we make an expression like the above before a people who do not understand that they cannot use it in moderation, it is an article that ought to be explained, or it should never have been published. No man can use opium continuously without an inclination to increase the dose, and under that increased dose the opium habit is formed, and when that is established no one, let him be what he may, can accomplish the true ends of life under it. Its effect upon the mind itself, if it did no more, precludes this. It over stimulates the impulses and imagination to the detriment of reason, will, and moral sensibility and thoroughly deranges the true economy of the whole being, physical, mental, and moral.

B. M. Woolley, M.D.

Atlanta, Ga., March 1, 1894.

WHY NOT REGISTER THE MALE PROSTITUTE?

To the Editor of the Medical Record.

Sir: As a means of control of prostitution, why not register the male syphilitic? Registering and licensing of the female prostitute does not control prostitution. I know this, because I had charge for several years of the Venereal Lock-hospital of the Yoshiwara of Tokio, that is, of the whole licensed system of prostitution of Tokio. That system, which was first established in 1867, did not prevent the archery girls and the numerous tea house girls from propagating venereal diseases. The two thousand licensed prostitutes were the smallest contingent to the army of prostitution. The great body was not under control. The lock hospital system proved to be simply a bug-a-boo! They feared that more than anything, as a licensed prostitute could not be relicensed without a certificate of cure from the hospital authorities. Those people, during the time of their sickness, were really in prison. They preferred opening archery establishments and tea-houses, and thus, unmolested by the law, exercise their trade and spread the poison.

The Russian Government at Nagasaki, in 1867, I think, opened for its own navy brothels of its own. The Japanese girls were examined and, when found healthy, were placed on trade for the use of the Russian marine. Even such careful proceedings did not prevent as much venereal sickness as was found in other navies. It was found that the officers of the navy propagated the disease, and not the women; they brought it from Calcutta, Singapore, and other Indian ports.

As to considering the moral part of the question, I think that it is not at all within the province of the medical profession. But, if we cannot put an end to prostitution, we can, at least, register the male syphilitic, and thus put on record the fact that he is a source of infection. I think even that it is our duty to do so. The diseased male will fear his record, if he fears nothing else, and people with marriageable daughters will have a means of protecting them.

Yours truly,

Albert S. Ashmead, M.D.

New York, March 29, 1894.

The Gresham University is the name by which the proposed teaching university for London will be known.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending March 31, 1894.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	4	2
Scarlet fever	115	13
Cerebro-spinal meningitis	0	0
Measles	258	24
Diphtheria	191	54
Small-pox	16	4
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

The Health of London.—From 1700 to 1750 the death-rate in London was so high that the population stagnated. In the former year the inhabitants numbered 665,200, and in the latter year 653,900. During this period the deaths were in the ratio of about one per thirty persons living. By 1801 the population had crept up to 777,000, and the deaths had fallen to one in forty-one persons living. This great improvement in the state of public health in London was not, except to a trifling extent, the result of sanitary legislation. People were becoming more enlightened on many matters affecting their health, partly owing to a more general knowledge of chemistry, physiology, and other sciences relating to man and his surroundings. When those intrusted with the conduct of public affairs became aware how much the health of the people was affected by bad water, by foul emanations, and cesspools, and by too great a density of population, they began to secure supplies of pure water, to construct proper house-drains and street-sewers, to remove systematically filth from houses, and to widen streets. The promulgation of the natural laws of health preceded the enactment of laws of health by the state. Jenner's discovery of prophylaxis in small pox had for its corollary the vaccination laws. The chemical analysis of water was the basis of acts of Parliament relating to water and rivers.

Bathing in Alaska.—In Alaska the method of taking a bath is somewhat heroic. Every trading post has a bath-house and the people are supposed to avail themselves of its privileges once a week. A person accustomed to living in a milder climate would have a good deal of hesitancy about undressing in one of these places, as the temperature is always below zero. In an inner room an arch of stones is built so that a fire made beneath can penetrate. A trap door in the roof answers for a chimney. After the stones have become thoroughly heated and the smoke has passed out, all the coals are removed and the trap-door closed. In this room stands a cask of warm water and another that is ice-cold. When the bather enters he pours hot water on the stones until the room is filled with steam; then, taking a seat on a bench, he waits till the perspiration streams from every pore in his body. Next he takes a bunch of dried twigs and leaves, prepared for the purpose, with which he scrubs himself till all the impurities have been removed from the skin, following this with a wash-off in warm water and soap. He concludes his bath by dashing a bucket of ice-cold water over his body, and then rushing to the dressing-room, where, with his teeth chattering and shivering in every limb, he resumes his clothes.

Ruskin and Charcot on the Grotesque.—Nowhere is the physician more directly opposed to the artist in his judgment than on the subject of grotesques. Take, for example, the grotesque head carved on the base of the tower of Santa Maria Formosa at Venice. Of this Mr.

Ruskin says: "A head—huge, inhuman, and monstrous—leering in bestial degradation, too foul to be either pictured or described, or to be beheld for more than an instant. Yet let it be endured for that instant, for in that head is embodied the type of the evil spirit to which Venice was abandoned in the fourth period of her decline. . . . This head is one of the many hundreds which disgrace the latest buildings of the city, all more or less agreeing in their expression of sneering mockery, in most cases enhanced by thrusting out the tongue. They are evidences of a delight in the contemplation of bestial vice and the expression of low sarcasm, which is, I believe, the most hopeless state into which the human mind can fall." It is rather refreshing, after this uncomfortable judgment on poor Venice, to turn to the doctor's diagnosis. M. Charcot writes: "In our opinion this distortion of the features, which gives the mask so grotesque and hideous an aspect, is by no means the result of a mere artistic whim. Nature, in her infinite variety of forms, is a mine of inexhaustible richness, where the beautiful and the ugly, the harmonious and the deformed, are mingled with intermediary degrees. The artist of Santa Maria Formosa, seeking for a grotesque type, seems to us to have met one in his path, to have seen it with his eyes, seized it in passing, and reproduced it with a fidelity which enables us at this day to recognize in it the signs of a pathological deformation of a nervous affection, clearly defined, of which we have had under our notice at La Salpêtrière very interesting examples. The case in question is evidently a spasm of the face, and presenting characters so marked that it is impossible to confound it with any other facial and spasmodic affection." Thus the physician comes to the rescue of the artist, and reveals a mere naturalistic *tour de force* in what the artist has read as "a delight in the contemplation of bestial vice."—*London Hospital.*

Tetanus Complicating Vaccinia.—Dr. S. W. Toms has recently reported in the Philadelphia *Medical News* a case of this probable nature. The patient, a strumous girl, five years of age, was vaccinated November 6th. Eighteen days later it was found that directions as to cleanliness had not been carried out by the mother, and at the site of inoculation there was an ulcer the size of a half dollar; deep and discharging fetid sanious pus. A week later the child took cold, had a sore throat and considerable trismus. Two days later general convulsions supervened. Three days after that she died of pulmonary œdema. Dr. Toms finds six similar cases recorded in medical literature. He says that from the period of time elapsing from the date of vaccination to the developing of the tetanus, it is certain that this does not correspond to the accepted view of the period of incubation.

In conclusion, the possible source of infection of the ulcer might have been from 1, vaselin (which might have been infected from previous use); 2, sponge (which might have been dirty); 3, unsterilized dressings; also from the solution of continuity of the mucous membranes of the mouth and throat.

Against the theory that it was due to vaccination is

1. The existence of "sore mouth," which is possible as offering a nidus for infection.

2. The date of onset not corresponding to the generally accepted period of incubation; and absence of bacilli of tetanus in the pus and tissue from the wound.

3. The fact that the disease manifested such a mild course, and that the fatal issue was dependent upon an intercurrent complication. Had not this unfortunate circumstance occurred, and had the child possessed ordinary vitality, it is but reasonable to assume that she would have recovered.

Protest Against a Pasteur Institute.—Some worthy souls in London, belonging to the anti vivisectionist wing of the Absurd, are greatly disturbed in mind by the proposed establishment of a Pasteur Institute in Chelsea, and are writing long protests to the London journals. The following is the style of one of their lamentations directed to the *Daily News*: "We desire to enter our earnest protest against the setting up of a Pasteur Institute in our midst (*sic*). It appears that no legal power can intervene to prevent the accomplishment of a design which is merely the offspring of a few physiologists, and for which there has been no public demand. We protest with all our might against the licensing by the Home Secretary of this gratuitous addition to the fifty-nine existing laboratories of what we believe to be a cruel and misleading science, and living as we do in and around the district where this horrible institution is to be set up, we claim that we and our fellow residents should have a right of veto over it as a public nuisance, dangerous to health, and involving animal suffering." Some of the names appended to this protest are of people who betray an ordinary intelligence in other matters.

Pizarro, a Congenital Criminal.—The three hundred and fiftieth anniversary of the death of Pizarro was recently celebrated with great pomp and circumstance in Lima, the city which venerates him under the title of founder. The mummy of the conqueror of peaceful aborigines, which lies in the cathedral at Lima, was disinterred and submitted to a thorough anthropometrical examination. It is hard to say why this indignity was put upon the poor old shrivelled remains, unless it is that they hoped to discover evidences of sanctity and gentleness of disposition which might be used in his process of beatification by the Church. The result of the examination hardly came up to their expectations, however, for on his skull were found the typical deformations, even the "fossa of Lombroso," which are regarded by the criminal anthropologists as infallible signs of moral degeneration.

Rome's Mineral Spring.—When Rome was first settled by Alban shepherds migrating to the banks of the Tiber to escape the dangers of the volcanic disturbances of their mountain home, the Campagna was dotted everywhere with mineral springs, which were even then celebrated for their healing virtues. Of these the only one still flowing in the neighborhood of the city is the one called Aqua Acetosa. The spring issues near the left bank of the Tiber, between two and three miles from Rome, in a well-house erected by Bernini at the request of Pope Alexander VII. The water is bottled every morning in wicker-covered flasks, like those in which the wine of Chianti is exported, and is peddled through the streets of the city for five centimes (one cent) a flask. The following is the composition of the water in parts per thousand:

Chloride of sodium	13.65
Chloride of calcium	0.57
Chloride of magnesium	0.10
Chloride of lithium	traces
Carbonate of sodium	1.15
Carbonate of calcium	7.87
Carbonate of magnesium	0.23
Carbonate of lithium	traces
Sulphate of sodium	2.26
Sulphate of calcium	0.11
Sulphate of magnesium	1.02
Silicic acid	0.11
Total	27.07
Free carbonic acid	9.36
Oxygen	0.15
Temperature of the water	61° F.

The New York Physicians' Mutual Aid Association.—From the recently issued report detailing the operations of this society for 1893 we learn that its present membership is one thousand two hundred and fourteen. There were eighteen deaths during the year. In each instance the sum of $1,000 was paid to the beneficiaries. The oldest death occurred at eighty-five, of "senility," and the youngest at twenty-eight, of typhoid fever. During the year fifty-three members were dropped for non-payment of dues, while four resigned. One year ago the by-laws were amended to allow the surplus in the assess-

ment fund to be used for the payment of a death-claim, whenever such surplus shall exceed $1,000. One claim has already been paid in that way. The funds of the association are summarized as follows:

Assessment fund	$4,481 99
Contingent fund	213 33
Permanent fund	19,372 63
	$24,067 95

Companionship in Convalescence.—It will be generally admitted that the term "illness" possesses a fuller meaning than can be explained by the mere presence of disease. The further stage of convalescence, hopeful and relatively healthy as it is, must also be included in the term. At best it is the approach to health, and its ailing incapacity must be reckoned with and provided for unless we would retard or frustrate the whole process of recovery. Conscious of this fact, some have even argued that a service of attendance is needful at this, as it manifestly is at an earlier, period. For the care of the skilled nurse they would substitute that of an invalid's companion. The office is not unknown to experience In one or other form it has existed, probably as long as that of the nurse, chiefly as a privilege of moneyed comfort. A novel extension has lately been proposed for the especial benefit of children convalescent from infectious disease, whose discomfort and isolation have excited the pity of some kind hearted persons. The suggestion is well intended, and wherever feasible might be put in practice. In some cases of partial recovery still requiring supervision for the purpose of its completion, such attendance might even be advisable on medical grounds. In such instances a nurse would be the fittest guardian. For the rest, the attentions of a judicious friend would usually afford the social advantages best suited to the needs and wishes of the convalescent. A system of regularly paid service, it appears to us, is in this case hardly called for, though voluntary assistance in aid of the parental care, if rendered with friendly tact, must often bring with it a truly grateful sense of relief.—*Lancet.*

The Changes in the Pharmacopœia.—The new Pharmacopœia of 1890 became official on January 1st. For the convenience of our readers we give a list of the new remedies which are now official, as well as of those which are no longer recognized. Certain changes in official nomenclature are important for correct usage in the future. There are eighty-eight new articles, and ninety have been omitted (*Boston Medical and Surgical Journal*). The newly adopted articles are the following: Acetanilidum, acidum hypophosphorosum dilutum, acidum stearicum, adeps lanæ hydrosus, alcohol absolutum, alcohol deodoratum, aloe barbadensis, aloinum, aqua aurantii florum (diluted), aqua chloroformi, aqua hydrogenii dioxidi, aqua rosæ (diluted), aspidosperma, barii dioxidum, caffeina citrata, caffeina citrata effervescens, calcii sulphas exsiccatus, cinnamomum saigonicum, cocainæ hydrochloras, convallaria elastica, elixir aromaticum, elixir phosphori, eriodictyon, eucalyptol, extractum apocyni fluidum, extractum asclepiadis fluidum extractum aspidospermatis fluidum, extractum cimicifugæ, extractum convallariæ fluidum, extractum eriodictyi fluidum, extractum jalapæ, extractum lappæ fluidum, extractum menispermi fluidum, extractum phytolaccæ fluidum, extractum rhamni purshianæ fluidum, extractum scoparii fluidum, extractum uvæ ursi, extractum viburni opuli fluidum, ferri et quininæ citras solubilis, glyceritum acidi carbolici, glyceritum acidi tannici, glyceritum boroglycerini, glyceritum hydrastis, hydrastininæ hydrochloras, hyoscinæ hydrobromas, hyoscyaminæ hydrobromas, lithii citras effervescens, menthol, methyl salicylas, naphtalinum, naphthol, oleatum zinci. oleum betulæ volatile, oleum cadinum, oleum terebinthinæ rectificatum, pancreatinum, paraldehydum, pepsinum, petrolatum liquidum, petrolatum spissum, physostigminæ sulphas, pilulæ catharticæ vegetabilis, pilulæ ferri carbonatis, potassii citras effervescens, pyrogallol, resorcinum, rhamnus purshiana, salol, sodii nitris, sparteinæ sulphas, spiritus amygdalæ amaræ, spiritus aurantii compositus, spiritus glonoini, spiritus phosphori, strontii bromidum, strontii iodidum, strontii lactas, strophanthus, suppositoria glycerini, terebenum, terpini hydras, tinctura lactucarii, tinctura quillajæ, tinctura strophanthi, trochisci santonini, viburnum opulus, zea.

The articles dismissed are: Abstractum aconiti, abstractum belladonnæ, abstractum conii, abstractum digitalis, abstractum hyoscyami, abstractum ignatiæ, abstractum jalapæ, abstractum nucis vomicæ, abstractum podophylli, abstractum senegæ, abstractum valerianæ, acetum lobeliæ, acetum sanguinariæ, æther, ammonii phosphas, ammonii sulphas, amylum iodatum, aurantii flores, azederach, cannabis americana, ceratum extracti cantharidis, ceratum sabinæ, charta cantharidis, chinoidinum, chloroformum venale, chincona flava, cornus, cupri acetas, cydonium, elixir aurantii, emplastrum ammoniaci, emplastrum asafœtidæ, emplastrum galbani, emplastrum picis canadensis, extractum cornus fluidum, extractum lactucarii fluidum, extractum malti, extractum mezerei, fel bovis inspissatum, ferri oxalas, galbanum, gaultheria, gutta-percha, hydrargyri sulphidum rubrum, ignatia, infusum brayeræ, juniperus, lavandula, linimentum cantharidis, linimentum plumbi subacetatis, liquor ferri et quininæ citratis, liquor gutta-perchæ, liquor pepsini, magnesii sulphis, magnolia, maltum, mistura magnesæ et asafœtidæ, mistura potassii citratis, mucilago cydonii, oleum lavandulæ, oleum rutæ, oleum succini, oleum valerianæ, origanum, pilulæ ferri compositæ, pilulæ galbani compositæ, pix canadensis, potassii sulphis, potassii tartras, prinos, rosmarinus, salix, sodii bicarbonas venalis, sodii santoninas, spiritus odoratus, syrupus ferri bromidi, syrupus limonis, thuja, tinctura conii, tinctura ferri acetatis, tinctura ignatiæ, trochisci magnesiæ, trochisci sodii santoninatis, unguentum acidi gallici, unguentum mezerei, unguentum sulphuris alkalinum, ustilago, vinum album fortra, vinum aloes, vinum aromaticum, vinum rhei, viola tricolor.

Di-iodoform and the Treatment of Chancre.—The Paris correspondent of *The Lancet* writes: Every surgeon must have arrived at the conclusion that as a dressing for soft chancres nothing equals iodoform; but the odor of this valuable compound militates greatly against its use, and attempts have accordingly been made to replace it by such iodine compounds as aristol, antiseptol, etc. Efforts have again been made to cover the odor of iodoform by means of coumarin, otto of rose, balsam of Peru, etc. Have we at last discovered the long-looked-for succedaneum in di-iodoform? MM. Maquenne and Taine have been recently engaged in investigating the properties of this new substance, which is an iodide of carbon, its ultimate analysis yielding: carbon, 4.62; iodine, 95.38. It is free from any trace of hydrogen and is remarkably rich in iodine. It is insoluble in water and only slightly so in alcohol and ether; it is easily soluble in chloroform, sulphide of carbon, benzene, and especially hot toluene. It crystallizes in fine prismatic needles, which are quite distinct from the hexagonal scales of iodoform. It remains practically odorless while it is kept in the dark. Exposed to the light it turns brown and disengages gradually a characteristic but slight odor. For this reason it is well to keep it in colored bottles. It is a very stable compound, resisting the action of boiling nitric acid. Hot alcoholic solution of potassium alone decomposes it with formation of iodide of potassium. Di-iodoform is prepared by acting on periodate of acetylene with iodine in excess, as also by the action of liquor potassæ and iodine on barium carbide held in suspension in benzene or chloroform. M. Hallopeau is engaged in studying its therapeutical effects in his skin wards at St. Louis. He has tried it in cases of soft chancres and finds its effects to be identical with those of iodoform. *A propos* of the local treatment of simple chancres, Dr. Balzer, of the Hôpital du Midi, expresses himself as highly satisfied with the following method: wash the surface with a 1 in

1,000 solution of corrosive sublimate or in a solution of boric acid, and then apply to the chancre, on a thin dossil of ungreased cotton wool, some europhene.

Medicine as a Career for Educated Men.—In an address delivered by Dr. W. W. Keen, of Philadelphia, before the Lafayette College Commencement in 1893, he said: "If any of you look forward to medicine as a career, you should view it from three different standpoints. First, on its economic side. This is a matter of no little importance, for every man in this world must earn his living, and also naturally looks forward to the support, not only of himself, but of his wife and children, in the future. No one should expect in medicine to make a fortune. A few doctors do so, but they are the exceptions. But every man who enters medicine, if he will be faithful and honest in his work, and *a fortiori* the more intellectual college man, can be sure of a competence —nay more, can be sure that he will enjoy not only the reasonable reward of toil, but be able to lay up sufficient for his own old age and for his family. Secondly, a much more elevating and attractive side is the philanthropic or humanitarian. The medicine of the future will be chiefly in the direction of that most philanthropic object, the prevention rather than the cure of disease. Hygiene or Preventive Medicine has only arisen within the last forty years. It has already done much, but it promises far more. If it is necessary to show that the knowledge of hygiene is still limited, look at the recent reports on the sources of the water-supply of New York. Nay, you need only go into the slums of your own city; or if you live in the more God-blessed country, you may find a startling ignorance of the laws of health in almost every farm-house. Nay, more, you need only cross-question a half-dozen of your intimate friends as to their modes of life, to discover that the laws of hygiene are 'more honored in the breach than in the observance.' But besides the economic and the philanthropic side, medicine has, thirdly, its splendid scientific aspect, which fuses with both of the others and yet may be regarded separately from them. Let me point out some of the best achievements and present problems of medicine. The present century has seen vast strides in every department of medicine. I will not weary you by mentioning the immense improvements made in many minor details, which would be more suited to a technical audience, but it is proper that I should allude to three brilliant discoveries which stand out prominently as of the first magnitude, viz., the discovery of anæsthetics, the inauguration of antiseptic surgery, and the establishment of the new science of biology. The twentieth century, in which you will live, will be the most glorious time of all the ages. But you may take part in this grand march of progress, not only in the rank and file, but as a leader, if you will but write. Or it may be, if you have the gift of imparting knowledge, you may be one of the teachers of medical science, an enviable post of honor and responsibility, but also of unequalled enjoyment. Have I not put before you enough to arouse the ambition, the energy, the benevolence, the enthusiasm, of any young man about to choose his career? Can there be in any other department of human knowledge so fine a field for research, for discovery, for fame, and, what is far better, for serving the human race? If, in consequence of what I have said to you, some of you will select medicine as your chosen pursuit, rest assured that if you will faithfully perform your duty, at the close of life you will have the pleasure of surveying a career which has been advantageous to yourselves, has been a means of doing good to your fellow-men, and I verily believe, has approximated as near as possible to the Divine Life as is given to any man to do."

Hard Times and Free Medicine.—From every part of this great and rich country the news comes to us of extreme stringency in the financial position of our *confrères*, the general practitioners. Never was there a richer opportunity for the masses to play the pauper than now. The present panicky state of the money-market affords people an immense excuse for wholesale imposition on the profession. The conditions of the times will not give them free bread, free clothes, free transportation on the railroads, or rent free, but they hie away to many of our too numerous hospitals and dispensaries for free treatment—advice, medicine, and all included for nothing, or for "ten cents," the figures fixed in certain palatial infirmaries. The consequence of all this has been most demoralizing to the profession and the public. Practitioners, reduced to a state of enforced idleness and grim want, are forced either to quit their profession altogether, or to "meet steal with steel," to open rival dispensaries, to advertise, or to drift into downright quackery. Many cases have come to our knowledge which go to prove that the practice in vogue in many of our largest dispensaries is a species of downright robbery, and tends to work incalculable harm to the profession. Case after case is taken from among the people of ample means and turned over to the hospital or to the college professor for his clinic, without a word being asked as to their mendicity or ability to pay anything at all. Cheap railroad excursion rates drain the outlying villages for miles in every direction. This hydra-headed monster of indiscriminate free treatment must be seized and strangled, or we will soon see the profession of medicine dragged in the dust; open downright quackery will be rampant, and integrity and honor in the healing art will be things of the past. By no means let us withhold our services to the poor and deserving, for humanity compels us to gratuitously attend those without means. Nor let us strip the field of such clinical material as legitimately belongs to the teacher; but let the teacher not forget that he has no prescriptive right to filch from the struggling practitioner what justly belongs to him.—*Medical and Surgical Reporter.*

BOOKS RECEIVED.

DESCRIPTIVE CATALOGUE OF THE ANATOMICAL AND PATHOLOGICAL SPECIMENS IN THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH. By Charles W. Cathcart. Vol. I., 605 pages. James Thin, Edinburgh, Scotland. Price, 7s. 6d.

SYLLABUS OF LECTURES ON THE PRACTICE OF SURGERY. By N. Senn, M.D. Oblong 8vo, 221 pages. W. B. Saunders, Philadelphia, Pa. Price, $2.00.

THE ART OF LIVING IN AUSTRALIA. By Philip E. Muskett. 12mo, 431 pages. Eyre & Spottiswoode, London, Eng.

SEWAGE DISPOSAL IN THE UNITED STATES. By George W. Rafter and M. N. Baker. 8vo, 598 pages, illustrated. The D. Van Nostrand Company, New York City.

THE ART OF MASSAGE. By A. Creighton Hall. 8vo, 144 pages, illustrated. The Scientific Press, Limited, London. Price, 6s.

CANCER, SARCOMA, AND OTHER MORBID GROWTHS. By J. J. Clarke. 12mo, 97 pages, illustrated. Balliere, Tindall & Co., London. Price, 3s. 6d.

DIGESTIVE PROTEOLYSIS.

THE CARTWRIGHT LECTURES FOR 1894.

BY R. H. CHITTENDEN, PH.D.,

PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN YALE UNIVERSITY.

LECTURE I.

PART II.—GENERAL NATURE OF PROTEIDS.

(Continued from p. 423.)

PROTEIDS are confessedly among the most complex bodies the physiologist has to deal with, while at the same time they are perhaps the most important, not only in view of their wide spread distribution through animal and vegetable tissues, but because of the prominent part they take in the nutrition of the body. The more our knowledge is broadened concerning these varied substances, the more we are impressed with their complexity, and at the same time with the necessity for a more accurate study of both their composition and constitution. Concerning the latter, full fruition of our hopes is probably in the distant future, but every step of advance in this direction adds greatly to our resources in the interpretation of the varied and complex changes characteristic of proteid metabolism. Every study of proteid decomposition adds something to our store of knowledge, and gives perhaps an added fact available for broadening our deductions.[1] Moreover, the composition and general reactions of the proteids may be investigated with full confidence of obtaining many useful results, which must necessarily be an aid in interpreting the changes accompanying digestive proteolysis.

Take, for example, the single question of peptonization by gastric digestion. What is the nature of the process? Is the proteid transformed into a soluble and diffusible peptone as a result of hydration and cleavage, or is it a transformation which results from a simple depolymerization of the proteid molecule, *i.e.*, are we to consider albumin and peptone as isomeric bodies? These questions, on which physiologists seem loath to agree, can certainly be answered definitely; not, however, by arguments but by careful experimentation, in which the composition of the proteid undergoing digestion must be a necessary preliminary factor, and the composition of the resultant product or products a secondary factor of equal importance. Further, the question needs to be answered not with reference to one proteid merely, but with reference to every proteid capable of digestion by either gastric or pancreatic juice. When these questions have been fully answered in this manner, we shall have positive data to deal with, and our conclusions will rest upon a foundation of fact not easily set aside. This is one of the problems upon which I have been at work for some years, and although progress may in one sense be slow, yet it is sure and gives results of no uncertain character.

First, then, let us consider briefly the nature of the proteids whose proteolysis we may be interested in; remembering, however, that in so doing we can merely touch upon the points essential for our purpose. Allow me to say in parenthesis that there is being published in Moscow a work on proteids alone of five volumes, 900 pages each, which it is supposed will constitute an exhaustive treatise of the subject.[1]

If we attempt to classify all of the proteid bodies hitherto discovered and studied we are at once confronted with a problem of no small proportions. So varied are they in their reactions, solubilities, and behavior toward general reagents, so inclined to merge into each other by almost insensible gradations that it becomes an extremely difficult matter to make an arrangement that will satisfy all the requirements of the case. I have to suggest, however, the following classification, which is merely a modification of several existing ones, based primarily upon chemical composition and solubility in the more common menstruums.

Proteids may first be divided into three main groups as follows:

I. *Simple Proteids.*—Composed of carbon, hydrogen, nitrogen, sulphur, and oxygen, and yielding by decomposition aromatic bodies such as tyrosin, phenol, indol, etc.

II. *Compound Proteids.*—Composed of a simple proteid united to some non-proteid body.

III. *Albuminoids.*—A class of nitrogenous bodies related to and derived from proteids, but differing especially from the latter by great resistance to the ordinary solvents of true proteids.

The individual members of these three groups may be arranged as follows on the basis of solubility, coagulability, etc.:

I. SIMPLE PROTEIDS.—*A. Soluble in water.—a.* Coagulable by heat, and by long contact with alcohol. Albumins: serum-albumin, egg-albumin, lacto-albumin, myo-albumin, vegetable albumins. *b.* Non-coagulable by heat and by long contact with alcohol. Proteoses:[2] proto-proteoses, deuteroproteoses. Peptones:[2] amphopeptones, antipeptones, hemipeptones.

B. Insoluble in water, but soluble in salt solutions.—a. More or less coagulable by heat. Globulins. 1. Soluble in dilute and saturated NaCl solutions. Vitellins. 2. Soluble in dilute NaCl solutions, but precipitated by saturation with NaCl. Myosins, paraglobulin[3] or serum-globulin, fibrinogen, myoglobulin, paramyosinogen, cell-globulins. *b.* Non-coagulable by heat, soluble in dilute NaCl solution and precipitated by saturation with NaCl. Heteroproteoses.

C. Insoluble in water and salt solutions, soluble in dilute alcohol—Zein, gliadins.

D. Insoluble in water, salt solutions and alcohol; soluble in dilute acids or alkalics.—a. Coagulable by heat when suspended in a neutral fluid. Acid-albumins, alkali albumins or albuminates. *b.* Non-coagulable by heat when suspended in a neutral fluid. Antialbumids, dysproteoses, glutenins.

E. Insoluble in water, salt solutions, alcohol, dilute acids and alkalies; soluble in strong acids, alkalies, and in pepsin-hydrochloric acid and alkaline solutions of trypsin.—Coagulated proteids, fibrin.[4]

II. COMPOUND PROTEIDS.—*A. Compounds of a proteid (globulin) with an iron-containing pigment, soluble in*

[1] See Drechsel: Der Abbau der Eiweissstoffe. Du Bois Reymond's Archiv f. Physiol., 1891, p. 248.

[1] Die Einheit der Proteinstoffe. Historische u. experimentelle Untersuchungen, by L. Morokhowetz.

[2] Used in the generic sense; the proteoses including albumoses, globuloses, myosinoses, elastoses, etc., and the peptones the peptone-products formed in the digestion of any or all proteids.

[3] Not completely insoluble in saturated NaCl solution.

[4] In blood-fibrin we have a good illustration of the fact that these divisions are not absolutely exact, since this form of proteid matter, for example, is somewhat soluble in dilute acids and in salt solutions, although requiring a long time for marked solution.

water and coagulable by heat and alcohol.—Hæmoglobin, oxyhæmoglobin, methæmoglobin, etc.

B. Compounds of proteids with members of the carbohydrate group. Insoluble in water: soluble in very weak alkalies.—a. True mucins. *b.* Mucoids or mucinoids.

C. Compounds of proteid with nucleic acid. Phosphorized bodies yielding by decomposition metaphosphoric acid. Insoluble in water and in pepsin hydrochloric acid, but more or less soluble in alkalies.—Nucleins.

D. Compounds of proteids with nucleins. Very soluble in dilute alkalies.—Nucleoalbumins, as casein of milk and nucleoalbumins of cell-protoplasm and cell-nuclei, etc.

III. Albuminoids.—*A. Soluble in boiling water with formation of gelatin and yielding by decomposition leucin and glycocoll*—Collagen (gelatin).

B. Insoluble in boiling water, and yielding by decomposition much leucin and some tyrosin, together with glycocoll and lysatin. Slowly hydrated by boiling dilute acids and by treatment with pepsin-hydrochloric acid.—Elastin.

C. Insoluble in water, dilute acids and alkalies, also in gastric and pancreatic juice. Yield leucin and tyrosin by decomposition.—Keratin, neurokeratin.

We may now advantageously consider the composition of a few of the more prominent representatives of the individual groups, taking for illustration those bodies which have been most thoroughly studied, and which we may have occasion to refer to in our discusssion of proteolysis. I have not included in the table any of the alteration-products of the proteids formed by the action of pepsin acid, trypsin or boiling dilute acids, confining myself here simply to those bodies which occur ready-formed in nature.

Composition of Some of the More Prominent Proteids Occurring in Nature.*

In considering the results tabulated above, it is to be remembered that all of these bodies, with the exception of keratin, neurokeratin, and reticulin, are more or less digestible in either gastric or pancreatic juice, or indeed in both fluids. I will not take time here to point out the obvious genetic relationships and differences in composition shown by the above data, but will immediately call your attention to the fact that there are other and more important points of difference between many of these proteids which are hidden beneath the surface, and which a simple determination of composition will not bring to light. I refer to the chemical constitution of the bodies, to the way in which the individual atoms are arranged in the molecule, on which hinges more or less the general properties of the bodies and which in part determines their behavior toward the digestive enzymes,

as well as toward other hydrolytic agents. These differences in inner structure can only be ascertained by a study of the decomposition products of the proteids, and of the way in which the complex molecules break down into simpler. The nature of the fragments resulting from the decomposition of a complex proteid molecule, gives at once something of an insight into the character of the molecule. Thus, egg-albumin exposed to the action of boiling dilute sulphuric acid yields, among other fragments, large quantities of leucin and tyrosin, the latter belonging to the aromatic group and containing the phenol radical. Collagen, or gelatin, on the other hand, by similar treatment fails to yield any tyrosin or other aromatic body, but gives instead glycocoll or amido-acetic acid in addition to leucin, lysin, and other products common to albumin. Its constitution, therefore, is evidently quite different from that of albumin, but the composition of the body reveals no sign of it. Further, we have physiological evidence of this difference in constitution in that gelatin, though containing even more nitrogen than albumin, is not able to take the place of the latter in supplying the physiological needs of the body; its food value is of quite a different order from that of albumin.

But while all of the individual proteids show many points of difference, either in composition, constitution, reactions, or otherwise, they are nearly all alike in their tendency to undergo hydrolytic decomposition under proper conditions; the extent of the hydrolysis and accompanying cleavage being dependent simply upon the vigor or duration of the hydrolytic process.

Furthermore, all of the simple proteids, at least, give evidence of the presence of two distinct groups or radicals, which give rise by decomposition or cleavage to two distinct classes of products. These two groups, which we may assume to be characteristic of every typical proteid, Kühne has named the anti- and hemi-group respectively. This conception of the proteid molecule is one of the foundation-stones on which rest some of our present theories regarding the hydrolytic decomposition of proteids, especially by the proteolytic enzymes. Moreover, it is not a mere conception, for it has been tested so many times by experiment that it has seemingly become a fact. The two groups, or their representatives, can be separated, in part, at least, by the action of dilute sulphuric acid (three per cent.) at 100° C. Thus, after a few hours' treatment of coagulated egg-albumin, about fifty per cent. of the proteid passes into solution, while there remains a homogeneous mass, something like silica in appearance, insoluble in dilute acid, but readily soluble in dilute solutions of sodium carbonate. This latter is the representative of the anti-group, originally named by Schützenberger[1] hemiprotein, but now called antialbumid.[2] It is only slightly digestible in gastric juice, but is readily attacked by alkaline solutions of trypsin, being converted thereby into a soluble peptone known as antipeptone. In the sulphuric-acid solution, on the other hand, are found the representatives of the hemi-group; viz., albumoses, originally known as one body, hemialbumose,[3] together with more or less hemipeptone, leucin, tyrosin, etc.

The fact that we have so many representatives of the hemi-group in this decomposition is significant of the readiness with which the so called hemi-group undergoes change. All of its members are prone to suffer hydration and cleavage, passing through successive stages until leucin, tyrosin, and other simple bodies are reached. These, and other similar crystalline bodies, are likewise the typical end-products of proteolysis by trypsin, and presumably come directly from the breaking-down of hemipeptone. Antipeptone, on the other hand, is incapable of further change by the proteolytic ferment trypsin. Hence the hemi-group can be identified by the behavior of the body containing it toward trypsin; *i.e.*, it will ultimately yield leucin, tyrosin, and other bodies of simple constitution to be spoken of later on. The anti-group, however, will show its presence by a certain degree of resistance to the action of trypsin, antipeptone being the final product of its transformation by this agent; *i.e.*, leucin, tyrosin, etc., will not result. In this hydrolytic cleavage of proteids the anti-group does not always appear as antialbumid. It may make its appearance in the form of some related body, the exact character of the product being dependent in great part upon the nature of the hydrolytic agent, but in every case the characteristics of the anti-group will come to the surface when the body is subjected to the action of trypsin.

The above-described treatment of a coagulated proteid with water containing sulphuric acid evidently induces profound changes in the proteid molecule. The conditions are certainly such as favor hydration, and in the case of complex molecules, like the proteids, cleavage might naturally be expected to follow. Analysis of antialbumid from various sources plainly shows that its formation is accompanied by marked chemical changes. Thus the following data, showing the composition of antialbumid formed from egg-albumin and serum-albumin by the action of dilute sulphuric acid at 100° C., gives tangible expression to the extent of this change:

	Egg-albumin.	Antialbumid[1] from egg-albumin.	Serum-albumin.	Antialbumid[1] from serum-albumin.
C.....	52.33	53.79	53.05	54.51

N.....	15.84	14.55	16.04	14.31

[1] Kühne und Chittenden: Zeitschr. f. Biol., Band 19, pp. 167 and 178.

In both cases there is a noticeable decrease in nitrogen, and a corresponding increase in the content of carbon. Evidently, then, this cleavage of the albumin molecule into the anti-group on the one hand, and into bodies of the hemi-group on the other, is accompanied by chemical changes of such magnitude that their imprint is plainly visible upon the resultant products; changes which certainly are far removed from those common to polymerization.

This proneness of proteid matter to undergo hydration and subsequent cleavage is further testified to by the readiness with which even such a resistant body as coagulated egg-albumin will break down under the simple influence of superheated water at 130° to 150° C. Many observations are recorded bearing on this tendency of proteid matter, but few observers have carried their experiments to a satisfactory conclusion. A recent study of this question in my own laboratory, has given some very interesting results.[1] Thus, coagulated egg-albumin placed in sealed tubes with a little distilled water and exposed to a temperature of 150° C. for three to four hours, rapidly dissolves, leaving, however, an appreciable residue. The solution reacts alkaline, there is a separation of sulphur, and in the fluid is to be found not albumin, but two distinct albumose-like bodies, together with some true peptone and a small amount of leucin, tyrosin, and presumably other bodies.[2] The albumose-like bodies are in many ways quite peculiar. In some respects they resemble the albumoses formed in ordinary digestion; but in others they show peculiarities which render them quite unique, so that they merit the specific name of atmidalbumoses, as suggested by Neumeister. What, however, I wish to call attention to here is the composition of these albumoses. Prepared from coagulated egg-

[2] Compare Neumeister's experiments on blood fibrin. Ueber die nächste Einwirkung gespannte Wasserdämpfe auf Proteine und über eine Gruppe eigenthümlicher Eiweisskörper und Albumosen. Zeitschr. f. Biol., Band 26, p. 57.

albumin by the simple action of heat and water, they show a deviation from the composition of the mother proteid, which plainly implies changes of no slight degree. This is clearly apparent from the following table:

	Coagulated egg-albumin.	Atmidalbumose precipitated by NaCl.	Atmidalbumose precipitated by NaCl + acid.	Deutero-atmidalbumose	Antialbumid.
C	52.33	55.13	55.04	51.99	53.79
H	6.98	6.93	6.89	6.60	7.08
N	15.84	14.28	14.17	13.25	14.55
S	1.81	1.66	....	0.98	....
O	23.04	22.00	....	27.18	....

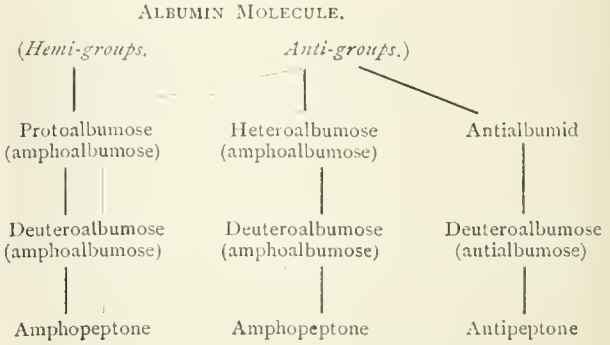
Here we see that two of these primary albumoses formed by the action of superheated water, like the previously described antialbumid, show a loss of nitrogen with a marked increase in the content of carbon. Evidently, they are related to the antialbumid formed by the action of dilute acid. They are, however, soluble in water, and in many ways differ from true antialbumid, but there is evidently an inner relationship. The so-called deuteroatmidalbumose shows a still more noticeable falling off in nitrogen and sulphur, while the content of carbon is more closely allied to that of the mother-proteid. The albumose precipitable by sodium chloride, although different from an albumid, evidently comes from the anti-group and is a cleavage product which in turn may undergo further hydration and splitting by continued treatment. The so-called deutero-body, on the other hand, may well be a representative of the hemi-group.[1]

It is not my purpose here to enter into details connected with the action of superheated water on proteids. Such a course would take us too far from our present subject, but I do wish to emphasize the fact that even the most resistant of proteids has an innate tendency to undergo hydration and cleavage, and that even simple heating with water alone, at a temperature slightly above 100° C., is sufficient to induce at least partial solution of the proteid. Further, this solvent action in the case of water and dilute acids, at least, is certainly associated with marked chemical changes. It is not mere solution, it is not simply the formation of one soluble body, but solution of the proteid is accompanied by the appearance of a row of new products, in which the terminal bodies are crystalline substances of simple composition. Further, this conclusion does not rest upon the results obtained from a single proteid, for I have at various times studied also the primary products formed in the cleavage of casein, elastin, zein, and other proteids by the action of hot dilute acid, and in all cases have obtained evidence of the formation of several proteose-like bodies, as well as of true peptones.

By the action of more powerful hydrolytic agents, such as boiling hydrochloric acid to which a little stannous chloride has been added to prevent oxidation, the proteid molecule may be completely broken down into simple decomposition products, of which leucin, tyrosin, aspartic acid, glutamic acid, glucoprotein, lysin, and lysatinin are typical examples.[2] In other words, by this and other methods of treatment, which we cannot take time to consider, we can easily break down the albumin molecule completely into bodies which, as we shall see later on, are typical end-products of trypsin proteolysis, and which are far removed from the original proteid. But, as we have seen, even the primary bodies formed in the less profound hydrolysis induced by superheated water, do not show the composition of the mother-proteid. Hydration and cleavage leave their marks upon the products, and thereby we know that solution of the proteid is the result of something more than a mere rearrangement of the atoms in the molecule.

[1] Compare Krukenberg, Sitzungsberichte der Jenaischen Gesellschaft für Medicin, etc. 1886.

[2] Hlasiwetz und Habermann, Ann. Chem. u. Pharm. Band 169, p. 150. Also Drechsel, Du Bois-Reymond's Archiv f. Physiol., 1891, p. 255.



Further, we are to remember that boiling dilute acid and superheated water tend to produce a cleavage along specific lines; viz., a cleavage into the anti- and hemi-groups of the molecule, and as representatives of these groups we may, in the hydration of every native proteid, look for two distinct rows of closely related substances.

In digestive proteolysis it will be our purpose to show that cleavage of much the same order occurs, not necessarily resulting, however, in formation of identically the same products, but certainly accompanied with the production of bodies belonging to the hemi- and anti-groups, although they may be less sharply separated from each other than in the cleavage with dilute sulphuric acid.

The body originally described as hemialbumose, and identified as a product of every gastric digestion, is now known to be a mixture of closely related substances ordinarily spoken of as albumoses,[1] or generically as proteoses. These are primary products in the digestion of every form of proteid matter, intermediate between the mother proteid and the peptone which results from the further action of the proteolytic enzymes. Associated with the hemi-albumoses are corresponding antialbumoses, coming from the anti- half of the proteid molecule, and differing from their neighbors, the hemi-bodies, mainly in their behavior toward the ferment trypsin. Thus, we have the counterpart of the many bodies described by Meissner, although now arranged systematically and on the basis of structural and other differences not thought of in his day.

By the initial action of pepsin-acid, proteids are first transformed into acid albumin or syntonin, then, by the further action of the ferment, this body is changed into the primary proteoses, proto and heteroproteose, of each of which there must be two varieties, a hemi and an anti. These may then undergo further transformation into what is known as a secondary proteose, viz., deuteroproteose, of which there must likewise be two varieties, corresponding to the hemi- and anti-groups respectively. By continued proteolytic action there results as the final product of gastric digestion peptones; approximately, an equal mixture of so called hemipeptone and antipeptone, generally known as amphopeptone. Such a peptone exposed to the proteolytic action of trypsin should obviously break down in part into simple crystalline bodies, leaving a residue of true antipeptone. In truth, this is exactly what does happen when the peptone resulting from gastric digestion is warmed with an alkaline solution of trypsin. The so called hemipeptone quickly responds to the action of the pancreatic ferment, and is converted into other products, while the so called antipeptone resists its action completely, thus giving results in harmony with our general conception of the proteid molecule.

On the basis of these facts, and others not yet mentioned, we may accept provisionally, at least, the following schematic view, suggested in part by Neumeister,[2] of the general line of proteolysis as it occurs in pepsin digestion; a view which clearly expresses the significant relationship of the hemi-and anti-groups in the proteid molecule.

[1] Kühne und Chittenden: Ueber Albumosen, Zeitschr. f. Biol., Band 20, p. 11.

[2] Zur Kentniss der Albumosen, Zeitschr. f. Biol., Band 23, p. 391.

The dark and light lines in this scheme are intended to represent the relative share which the hemi- and anti-groups take in the formation of the individual bodies. Thus, we see that protoproteoses have their origin mainly in the hemi-groups of the molecule, although, as the fine line indicates, anti groups are somewhat concerned in their construction. Heteroproteoses, on the other hand, come mainly from the anti-groups, but still some hemi-groups have a part in their structure. As previously stated, these two primary proteoses by further hydrolytic action may be transformed into secondary products; viz., into deuteroproteoses, but, as the above scheme indicates, the two deutero bodies will be more or less unlike in their inner nature. In one sense, they are both amphodeuteroproteoses, but they necessarily differ in the proportion of hemi- and anti-groups they contain. By the still further action of pepsin-acid, the deutero bodies may be changed, in part at least, into peptone, *i.e.*, into amphopeptone, although, as Neumeister has pointed out, protoproteose tends to yield an amphopeptone in which the hemi-groups predominate, while the peptone coming from heteroproteose contains an excess of anti-groups. Moreover, in the gastric digestion of any simple proteid a certain number of anti-groups are split off in the form of antialbumid, a body which is only slowly digestible in pepsin-acid. By the very powerful proteolytic action of a strong gastric juice, however, antialbumid may be somewhat digested, and is then transformed into antideuteroalbumose, which in turn may be eventually changed into antipeptone.

From these statements it is evident that a given proteid exposed to pepsin proteolysis may give rise to a large number of products; in fact, to a far larger number than is implied by the names in the above scheme. Thus, at first glance you would be inclined to say there can be only three deuteroalbumoses, for example; one, a pure anti-body, the other two, amphoalbumoses, differing from each other simply in their content of hemi- and anti-groups. It must be remembered, however, that the inner constitution of these bodies, as implied by the relative proportion of the above groups, may vary to almost any extent. Thus, every variation in the number of anti-groups split off from the original albumin molecule to form antialbumid means just so much of a change in the relative proportion of hemi- and anti-groups entering into the structure of both primary and secondary albumoses. Hence, as you can see, digestive proteolysis, even in gastric digestion, is a somewhat complex process. We have to deal not only with a number of bodies superficially unlike, as the primary and secondary proteoses and peptones, but these bodies may show marked variations in structure dependent upon the exact conditions attending their formation.

Evidently the complexities attending digestive proteolysis are connected primarily with the complex nature of the proteids themselves, while proteolysis, as a process, is made possible through the natural tendency of the proteids to undergo hydration and cleavage.

The Zulu Treatment of Pain in the Stomach.—Cetewayo had a pain in his stomach, and two of his children were unwell. "Why do you not do something to prevent it?" inquired an English visitor. "So I do," replied the great chief. "No one can tax me with neglect of my duty in that respect. I have been killing witches right and left, but the more of them I kill the more there seem to be." And he gave a great sigh.

More Bogus Diplomas.—From a correspondent in Toronto, we learn that a short man with generous ventral dimensions, a fugitive from justice in that city, is now selling bogus diplomas with the degree of M.D. attached to them, and has had quarters in Boston. It is thought that his portrait adorns the Rogues' Gallery in New York. He is wanted in Canada for fraud, in connection with the running of a loan and trust company.

AN ANALYSIS OF THE HECTIC PHENOMENON: WITH REMARKS ON THE TREATMENT.[1]

By HENRY S. STARK, A.M., M.D.,

NEW YORK.

In attempting to narrate our views of the character and significance of hectic fever within the narrow scope of a short paper, we cannot hope to be more successful than to convey a very faint impression of its importance. There are extant any number of descriptions of this fever, but the splendor of the portrayal that Charles Dickens gives us of it in his "Oliver Twist" stands out in such bold relief in comparison to the dull scientific phraseology of medicine that it must have found its way into more than one medical volume.

Throughout the entire gamut of subjective symptoms I know of none which appeals more strikingly to the conscience of the patient and the sympathy of the physician than the complex condition which is the subject of this paper. So commonly prevalent in a host of affections, so painfully recurrent, so profoundly impressive, it appears as though Nature in her munificence intended this thermometric phenomenon as an early and significant warning, a beacon, as it were, to arouse suspicion of a threatened invasion of the vital forces. Is it then to be wondered at that from time immemorial investigators have busied themselves with the study of its interpretation? To-day, thanks to our newer knowledge, the profession is in possession of a law which is the ultimate and inevitable outgrowth of these successful studies. That law is, that hectic fever means pus, or rather, if you please, pus-generating micro-organisms. The character of the pus is irrelevant; it may abound in the cocci of Rosenbach or of Passet. The quantity of pus is irrelevant; it may be microscopic in quantity or appreciable to the naked eye. Even the site of the pus is irrelevant; it may be localized to a microscopic area or it may be diffused over different and distant parts of the body. The point of importance is that, when once this typical fever is firmly established, the idea of suppuration cannot be thrown out of the field. In an article on "Suppurative Fever," which appeared in the New York MEDICAL RECORD of February 1, 1890, I stated, to quote from myself, that "hectic fever is nature's method of announcing pus, for just as in physics it is said that 'nature abhors a vacuum,' so in medicine it may be said that nature abhors pus in the living economy." To-day, with a riper experience and a more extensive knowledge of the subject, I am only the more convinced of the correctness of this statement.

It is necessary at the outset to draw a distinction between a characteristic hectic movement and the simple chill followed by a febrile movement, the latter phenomenon being such a frequent heralder of a variety of affections. The distinguishing characteristics of the former are a cold, a hot, and a sweating stage. The concomitant symptoms that accompany each stage are too familiar to require enumeration here; suffice it, however, to state that the amount of perspiration is not necessarily in proportion to the intensity of the fever. Thus the temperature may be scarcely appreciable to the patient, and yet may be followed by a most profuse sweat, which may exhaust the patient sufficiently to make him somnolent or to prostrate him. There may also be a marked disproportion between the intensity of the morbid process and the temperature. Thus in a long-standing case of pulmonary tuberculosis, with extensive pulmonary involvement, the daily temperature may be slightly elevated while the colliquative sweat may also be insignificant. The latter disproportion seems to depend upon the duration of the pathological process and upon the age of the patient. Old age seems to enjoy a compara-

[1] Read at a meeting of the Metropolitan Medical Society of New York.

tive immunity from severe attacks of the hectic cycle. I have frequently confirmed this observation at the bedside, and no doubt my hearers have also.

What relation of cause and effect there may be between the degree of fever, the severity of the morbid process, and the quantity of perspiration, is a matter for which, at present, no feasible explanation can be offered. Still more mysterious are the regularity and promptness in the recurrence of each stage and of the cycle as a whole. The same hour of each day will witness the same stage, with almost astronomical precision. So much so, that patients with a long-standing suppurative disease learn to await their daily fever matinees with a feeling of resignation somewhat akin to respectful awe and bordering on utter helplessness. The three stages of the hectic movement, then, form a triad of symptoms which cannot be precisely duplicated in the whole domain of semeiology, and which renders the differentiation between it and other febrile affections fairly easy.

The differentiation between the hectic cycle and the initial febrile movement of other affections is not attended with many difficulties when it is remembered that in the latter there is usually only one such chill followed by an increased temperature, and that occurs at the very onset of the disease.

The differentiation, however, between hectic fever and the various varieties of the malarial fevers, especially those of a quotidian type, is not so easy. In many such cases time alone is the determining element. Points of distinction, however, are the following: In hectic fever the daily paroxysm begins in the afternoon, in malarial fevers it begins most frequently during the morning hours; in hectic fever the chill takes place at almost the same hour of each day, while in quotidian malaria the chill may recur at an earlier or a later hour than on the previous fever day. Further, the rhythm in malarial fevers may become so completely changed that a quotidian type is transformed into a tertian, or *vice versa*. In malaria one or two of the three phases in the cycle of events may be continually absent, either the chill or the sweating stage. In hectic fever, however, the three events follow in an almost immutable succession. In making the above distinctions I refer, of course, only to such individual cases as are not at once accompanied by characteristic signs or by pathognomonic symptoms. Naturally enough, there occurs a generality of cases in which the discriminating diagnosis between hectic and the malarial fevers is made readily enough from the signs and symptoms that directly or subsequently unfold themselves. The periodical fevers of malarial origin present not only the above points of distinction, but offer a marked contrast in the laws which govern their causation, duration, periodicity, and their amenity to specific medication.

Such types as intermittent and remittent fevers conform so severely to certain well-known laws of periodicity of their febrile action that their recognition and differentiation is rendered comparatively easy. In intermittent fever, for example, there occurs a daily febrile intermission between the paroxysm, an afebrile term, while in remittent fever there occurs a well-marked remission of the temperature, a low fever term. All this is in such striking contrast to the daily chill, fever, and exhausting sweat of hectic fever as to make it appear that the differentiation, after all, is not beset with insurmountable obstacles.

The specific poison of the malarial fevers is now well established upon a morphological basis, while the specific poison or poisons of hectic fever are equally well known and hold a distinct place in our bacteriological nomenclature. So that, should the clinician become baffled, the pathologist would come to his rescue.

The differential diagnosis between hectic fever when accompanied by severe prostration, or coma, or icterus, or gastric and intestinal disturbances, and certain continued malarial fevers, when accompanied by these particular symptoms, such as pernicious intermittent fever, is often a fruitful source of difficulty and apprehension. For the clinical pictures in both instances resemble each other so closely that a close clinical differentiation is well nigh out of the question. In these instances the first inquiry, naturally, would be in regard to the type of fever prevailing in the locality at the time. The absence or prevalence of the malarial type would be the main point of reliance; secondly, the presence of characteristic lesions would appear to afford *à priori* evidence.

The value of the hectic phenomenon as an aid to diagnosis cannot be alluded to with sufficient emphasis. Often, when all other symptoms fail of interpretation and the physician's efforts to unravel the character of his patient's disease meet with no response, the recognition of the hectic phenomenon furnishes the key to the solution of the diagnostic problem. Time and time again this has been the experience of novice and of expert. In tuberculosis, for example, the hectic cycle warns us that there must be present a suppurative breaking down of lung parenchyma. In many of these cases the thermometer, by detecting a hectic movement, will enable one to form a correct judgment of the condition of the lung long before the physical signs and symptoms reveal the presence of consolidation. This rule applies with double weight in the case of children, for in many of these the continued daily hyperpyrexia is the first and only symptom for a time. I have seen it present to the entire exclusion of all the other subjective symptoms that are usually associated with pulmonary tuberculosis.

Conversely, the *absence* of the hectic fever is often as much of an aid in the diagnosis of certain maladies whose nature remains obscure for a while as its *presence* is in other maladies. Thus in a case of pleurisy with effusion the absence of the hectic phenomenon would be interpreted to mean that the pleural effusion was serous and not purulent, and so in all other febrile maladies accompanied by exudations this observation would apply equally as well.

In surgical diseases the recognition of the hectic phenomenon is the mainstay to diagnosis. In doubtful cases of suppuration the surgeon places his main reliance on the presence or absence of this febrile movement. Often, as in deep-seated, indistinctly fluctuating swellings, such as a pyosalpinx, a nephritic, hepatic, typhlitic, or pelvic abscess, outside of surgical or manual interference, the hectic fever is the sole criterion of the presence of a purulent fluid. And so, after an elaborate surgical dressing has been applied over a freshly operated part with a view of having it remain a number of days, should the typical hectic fever develop the surgeon recognizes the fact that suppuration has taken place.

If, now, so much importance attaches to this variety of fever, the question of its origin and character is a matter of much interest. This inquiry would bring us into touch with the prevailing theories regarding the origin of fevers. This is a point I do not intend to discuss further than to allude to the microbic theory of the origin of fevers as it applies to hectic fever, since in the present state of our knowledge it is not possible to explain satisfactorily the *modus operandi* by which all the varied phenomena of the fevers are produced. At the present day it is generally accepted that there is an inseparable etiological relation between micro-organisms and inflammations; in other words, the *sine qua non* of an inflammation is a microbe. In the case of hectic fever, as is well known, it would be the streptococci or staphylococci of Rosenbach or of Passet. Now the broad application of this theory, from a pathological stand-point, would mean that hectic fever is a constitutional phenomenon due to absorption into the blood through the avenue of the lymphatics of the pus-generating cocci or of their toxic products and chemical *débris*, the *materies morbi* acting on the blood as a ferment. The poison, having entered into the general circulation, produces symptoms of a constitutional character and affects the entire organism. But like many other specific poisons it is known to exercise a selective affinity on special organs. In the case of

hectic fever it is my opinion that the poison exhibits a selective influence on the nerve-centres. In that event it would appear that hectic fever was a poisoning of the nerve-centres, and this is exactly the stand I shall assume. This theory would furnish certain natural general principles of treatment, based on its morbid anatomy and its pathogenesis, to which I shall later invite your attention in this paper.

The nerve-centre intoxication varies in its intensity, according to the quantity and character of the blood-contamination, the pre-existing state of the innervation, and the power of resistance of the body to the operation of morbid products. Thus the toxic elements may be so insignificant in quantity and character as not to occasion any appreciable derangement of any organ, or to exert any elective affinity on any tissue. In such cases the symptoms would not be sufficiently prominent to attract attention from either patient or physician. Instances of this kind of hectic fever are the obscure febrile movement that accompanies a beginning felon, a small abscess, a beginning pus formation in the Fallopian tube or in a serous cavity, and the fever that is sometimes observed to follow urethral instrumentation.

The palpable evidence, as it were, that can be produced to confirm the position that this fever is a microbic intoxication of the nerve-centres is based upon an anatomical interpretation of the phenomena of the fever. The most familiar phenomenon is the hectic flush. This, in medical parlance, is nothing more or less than a nerve-centre phenomenon; a dilatation of the cutaneous arterioles, caused by a stimulus in the central nervous apparatus, from which point as a centre the stimulus is transmitted to the vaso-motor system, the muscular fibres of which relax, the artery dilates, and a suffusion or flush results. This mechanism is started in the poisoned nerve-centres.

Another prominent feature of hectic fever whose origin is found in an altered condition of the central nervous system is the profuse perspiration. Experimental evidence of physiologists has established the fact that the mechanism of this function is often under the control of the central nervous system. It may be brought about as the result of a reflex act. Physiologists speak of "sweat-centres" in the spinal cord, just as we speak of vaso-motor centres. We are therefore led to infer that there are special nerve-fibres, emanating in the spinal cord, which control to a large degree the activity of the sudoriferous glands. Familiar examples of these facts are the profuse ante-mortem sweats, the sweats that accompany the crises of certain diseases, and the sweats that follow certain mental emotions, as fear or fright.

Still further evidence in favor of the view that the nerve-centres are immediately concerned in originating this species of fever is found in some well-established physiological facts. First, it is known that the spinal cord may originate, regulate, and influence body heat. In short, that the spinal cord may be the starting-point of the fever. Second, it is known that the nerves supplying the blood-vessels and sudoriferous glands act in concert in health and in disease. Third, it is known that certain nerve-centres preside over certain functions to the exclusion of all other functions.

An explanation of the pathogenesis of hectic fever, based upon the theory of a reciprocal relation between it and the process of suppuration, is at once beset with the broad objection that experience and experiments have demonstrated the possibility of a non-microbic suppuration. But, granted that there is such a possibility, my conclusion is still warranted. For I do not claim that hectic fever accompanies every suppurative process, or that every suppurative process exerts an influence on the nerve-centres. On the contrary, it is a matter of daily observation that pus-generating cocci of the most virulent character may be absorbed without eliciting the faintest hectic movement, and that a suppurative process may be in a state of activity for months and years without ever provoking the hectic phenomenon. Examples to illustrate these facts could be enumerated by the score. It is therefore fair to assume that when once the characteristic micro organisms of suppuration find their way, through the avenue of the blood-vessels or lymphatics, to the nerve-centres, then they invariably provoke the fever.

Now, what elements influence this immunity of the nerve-centres on the one hand, or their susceptibility on the other hand, cannot be easily determined in the present imperfect state of our knowledge, without offering *bizarre* theories and wild speculations. There are, however, certain experiences which appear to throw some light upon the matter. Thus it appears from experience that non-microbic suppuration is rarely accompanied by the hectic movement. The suppuration apparently provoked by external irritants, such as heat, light, air, or chemicals, and that produced by pressure effects and movement, is hardly ever accompanied by a decided hectic spell. Such facts, to say the least, add plausibility to the theory that pus-generating cocci are the *sine qua non*, and that the fever is neither idiopathic nor coincidental. Further evidence to reconcile the theory that the nerve-centres are the objective points of the microbes is the well-known observation, that directly you rid the site of suppuration of microbes, by incision and drainage, that is, you remove the local source of irritation, the hectic abates, only to recur when retention or accumulation of pus follows, and the organisms again assail the nerve-centres.

As far as the treatment of this fever is concerned, I have already alluded to the fact that certain general principles can be adduced from a knowledge of its pathological nature. The specific poison being known, its locality is to be ascertained that it may be eliminated from the economy. It is a cardinal rule of surgery to get rid of pus wherever discovered, and as speedily as is consistent with the exigencies of the case. To discover its presence and site every resource known to medicine and surgery should be called into requisition without fear or hesitation. The first general principle, then, is to remove the local source of irritation, whenever possible, through surgical interference. There are certain low forms of hectic fever depending upon a nerve-centre poisoning of moderate or slight intensity the treatment of which can be relegated entirely to nature's reparative power. In some of these cases the quantity of pus is quite appreciable to touch and to sight. I think most of you are familiar with instances of this nature. Purulent pleurisies, purulent peritoneal inflammations are sometimes of this type. A case of this kind occurs to my mind at present—a female with pelvic inflammation accompanied by hectic fever. Pus was demonstrated by exploratory puncture. For divers and diplomatic reasons operative interference was withheld, the cure of the disease having been left to nature's reparative power with a successful issue. How far and when we may rely upon nature to bring about a favorable issue must be determined by consulting the condition of the patient and the character of the affection. No hard-and-fast rules of regulation can be framed. When, however, the two alternatives are presented, of firstly leaving the case to nature, and secondly to the physician, it is well to remember that between the two the physician is by all odds the better healer. The criterion for action with me has been the amount of exhaustion, the rapidity of emaciation, and the intensity of the fever. Thus, if the nervo-muscular prostration is great and rapid, heroic measures are preferable to procrastination, and whenever it is apparent that the purulent inflammatory products threaten to invade a vital locality, it is advisable to act energetically, despite the fact that pathologists inform us that the system will always tolerate a certain amount of microbic intoxication with comparative immunity and will supply the constitutional antidote unsolicited and unaided. The intrinsic tendency of hectic fever to disappear, at times, through the *vis medicatrix naturæ* by a process of retrograde metamorphosis of the inflamma-

tory products is then to be taken into consideration in reference to its management. I don't, however, mean to infer that the physician should stand by as a mere spectator; on the contrary, his judgment and usefulness will come mainly into play in determining the relative merits of nature and art as curative agencies.

Passing now to the consideration of drugs for the alleviation of the symptoms, the therapeutic indications have reference to the colliquative sweat, the chill, the nervo muscular prostration, and the hyperpyrexia. As far as the treatment of the hyperpyrexia is concerned, I have nothing new to offer. In regard to the treatment of the colliquative sweat and the prostration, however, I wish to put myself on record in favor of two drugs which have served me admirably, after having experimented with a variety and having subsequently discarded them. These drugs fulfil the physiological and pathological indication in a way that commends them favorably to all practitioners. They are, for the sweat and prostration, atropine, and for the prostration and circulatory disturbances, strychnine. For several years, both in public and private practice it has been a matter of routine with me to combine the salts of atropine and strychnine in a palatable manner in the treatment of this fever complex, and I have up to date yet to learn of a more effective combination. A serious drawback to the freer employment of these powerful drugs has always been the imminent danger of miscalculating the dosage or in committing a chirographical or a mathematical error in writing the prescription or in having it compounded. I actually know of one physician who has absolutely stricken these drugs from his personal pharmacopœia on that account. It would appear that this *quasi* obstacle ought not to militate against their use, as it could readily be overcome, to the interest both of the public and of the profession, with a little precision, heroism, and self confidence on the part of the practitioner.

The mode of operation of these drugs is of importance. It is known that both are cardiac tonics, under certain conditions, which do not at all antagonize each other, inasmuch as they act differently on different functions. Thus atropine, according to therapeutists, has a paralyzing action on the inhibitory fibres of the pneumogastric and at the same time stimulates the cardiac ganglia of the sympathetic; strychnine increases arterial tension and the force of the apex beat. Further, atropine, if properly administered, will check the profuse sweat that so surely exhausts and prostrates, and will also allay the irritability of the central nervous system. Strychnine is the remedy, *par excellence*, as a general tonic for the nerve centres; in this respect it is almost a specific. The exhaustion and depression caused by the nerve-centre poisoning find here a remedy which strikes at the very root of the affection, without in any way impairing the cerebral functions. I am aware that some writers discourage the employment of strychnine in the acute stage of spinal disease, but my experience does not warrant such a conclusion, as I have as yet to note an untoward effect or an unpleasant result. *En passant*, I recall a very severe case of hectic fever accompanying a pyonephrosis, in which there was a daily collapse for three successive days, due to the hectic phenomenon. Strychnine and atropine were administered, to the exclusion of all other drugs, and I verily believe that they were the means of tiding the victim over the critical period, until an operation was deemed advisable, by economizing his vitality and strengthening the circulation and innervation. The mode of administering these drugs is as follows: I usually combine both salts of the alkaloids in pill form. Of atropine, the adult dose should be $\frac{1}{200}$ to $\frac{1}{90}$ grain; of strychnine, $\frac{1}{60}$ to $\frac{1}{30}$ grain. They should be administered one or two hours before the anticipated chill in one large dose, or else in divided doses t.i.d. I usually give $\frac{1}{100}$ atropine and $\frac{1}{30}$ grain strychnine to adults. As far as the atropine is concerned its effects are delayed at times for one or two days, or its influence may be extended over a like period. Slight atropinization occurs at times, but tetanization never. On this account it is preferable to study the idiosyncrasy of the patient and his tolerance by administering each drug independently at first. I never employ any preparation except the alkaloids themselves, and even in the case of children this rule applies with double strength, for it is an ordinary observation that they tolerate atropine much better, comparatively, than adults do.

The administration of these alkaloids in no way interferes with the action of other drugs that may be employed for the reduction of temperature; on the contrary, they enhance their value by counteracting the depressing effects on the heart of the synthetical antipyretics of recent date. It is scarcely necessary to state that not all cases of hectic fever are to be combated with atropine and strychnine, singly or conjointly. There are many instances of this fever which entirely abate directly the local source of irritation is removed. The point intended to be emphasized is this, that these drugs are of decided benefit for the amelioration of the symptoms in those cases where the pus nidus cannot be precisely located, or where operative procedures are advisedly delayed or expressly abandoned for conservative reasons. In that type of hectic which consists merely of chill and hyperpyrexia atropine should be discarded.

The following are some formulæ which cover the points brought out by this paper and which are employed by me.

When hyperpyrexia is insignificant, but the chill, sweat, and prostration are the prominent features:

No. 1.

℞. Strychninæ sulphat ..... gr. $\frac{1}{8}$
Atropini sulphat..... gr. $\frac{1}{100}$
Extr. gentian..... q. s.
M. et F. in pilulas No. xii.
S.—One t.i.d.

When all the symptoms are present:

No. 2.

℞. Strychninæ sulph..... gr. $\frac{1}{8}$
Atropini sulph..... gr. $\frac{1}{100}$
Antifebrin ..... ʒ j.
M. et F. in capsulas No. xii. aut oblat.
S.—One t.i.d. or p.r.n.

When the sweating stage is absent, but the temperature and prostration predominate:

No. 3.

℞. Strychninæ sulphat..... gr. $\frac{1}{8}$
Phenacetin..... ʒ ij.
Caffein citratis..... grs. xxiv.
M. et F. in oblat. No. xii.
S.—One wafer t.i.d. aut p.r.n.

To sum up, I would submit the following conclusions: 1. A typical hectic fever means a pyogenic intoxication. 2. The objective point of the micro-organisms is the spinal nerve-centres. 3. From a physiological and therapeutical stand-point the drugs most immediately indicated are strychnine and atropine.

270 Seventh Street.

A Sonnet on the Retirement of William Howship Dickinson, M.D., F.R.C.P., from the Working Staff of St. George's Hospital.—

Physician thou for twenty years hast been,
To our St. George's School a faithful friend—
A teacher among teachers to the end;
And a great scholar, too, as all have seen.
In observation thou didst always lean
On Nature first, so thou couldst well defend
Thy theories. None ever saw thee bend
The blade of Truth to fit thy thought so keen.

Farewell! We will not write a song of praise
To thee, but rather store within our mind
A memory of thyself, for we did find
Duty and truth thy foremost aims. We raise
Our voice in one, that thy remaining days
Be full of joy, and Old Age to thee kind.

—T. W. P.

VEXED QUESTIONS IN THE BACTERIOLOGY OF DIPHTHERIA.

By WALTER F. CHAPPELL, M.D.,

NEW YORK.

In view of the presence or absence of the Klebs Löffler bacillus being almost universally accepted in this city as a proof of diphtheria or not, the following cases will doubtless prove interesting:

During the latter part of January of this year, while making some investigations with Dr. William Hallock Park, of this city, with a view of settling the question of the contagious or non contagious character of follicular tonsillitis, I examined the throats of forty-seven children in the New York Orthopedic Hospital, and noted the ones having enlarged and diseased tonsils or unhealthy-looking throats. Dr. Park subsequently made cultures from some of the throats which were found to be abnormal in appearance. Dr. Park reported that, from two of these throats, he obtained pure cultures of typical Klebs-Löffler bacilli growing in fair abundance; in two others they were also present, but were few in number.

The histories of the cases containing the greatest number of Klebs-Löffler bacilli, were as follows:

Case I.—Mary M——, nine years of age, has been in the hospital since August 23, 1892, suffering from knee and spinal disease. Her left tonsil was moderately enlarged, but healthy in appearance; posterior wall of the pharynx quite red. During her stay in the hospital, one year and five months, she has had several attacks of indigestion, but no sore throat, and was perfectly well at the time of the examination.

Case II.—Emily B——, aged twelve, in the hospital since November 1, 1893, suffering from club-foot. Right tonsil moderately enlarged, Klebs-Löffler bacilli abundant. With the exception of an acute attack of indigestion, has had no illness since she came to the hospital.

Case III.—May C——, in whom the bacilli found were reported to be of a doubtful character, has tubercular hip joint disease. Her tonsils are moderately enlarged, but healthy in appearance. Her throat has not been sore, neither has she appeared sick since her admission.

The children in this hospital seem specially liable to attacks of follicular tonsillitis, but there had been no recent case, neither had there been any diphtheria in the hospital.

Beside the report made by Dr. Park, I made two cultures, which were examined by a bacteriologist, who did not know the source of the specimen, nor the previous results obtained. His report was similar to Dr. Park's.

From the surroundings and his examinations of the patients, Dr. Park expressed doubts about the virulent character of the Klebs-Löffler bacilli found, and subsequently reported that from inoculation he had found them to be non-virulent.

Until these cases were examined I supposed that Klebs-Löffler bacilli found in a sore throat meant diphtheria, whether the clinical history and appearance supported that diagnosis or not. If we have to rely on inoculation for the final test as to the true character of the bacilli, the simple finding of the Klebs-Löffler would not be available for reliable and rapid diagnosis, as non-virulent Klebs-Löffler might be found in a person suffering from follicular tonsillitis.

Does the inoculation of an animal with the Klebs-Löffler bacillus, producing virulent results, necessarily prove that this bacillus is the cause of diphtheria in man?

Might not the character of the bacilli be determined by the nature of the soil in which they grow?

At present writing it seems there are three possibilities: 1, Clinical phenomenon of diphtheria without Klebs-Löffler bacilli; 2, clinical phenomenon of diphtheria with Klebs-Löffler bacilli; 3, Klebs Löffler bacilli without any clinical phenomenon of diphtheria.

CHLOROFORM IN ORGANIC DISEASES OF THE HEART.

By FISHER R. CLARKE, M.D.,

STOCKTON, CAL.

There is a very generally prevailing opinion among the profession that chloroform should not be given in organic heart disease; in other words, that it is a dangerous drug to administer, even to a slight degree, where dilatation, valvular disease, fatty degeneration, or any organic or functional trouble exists that gives rise to a weak and imperfect circulation; while complete anæsthesia would be almost certainly fatal. So dangerous is this drug under these conditions that many of our authors teach that it should not be administered to any patient until a careful stethoscopic examination of the heart and lungs has been made. This idea is so well established and so generally believed that even the laity are well informed on this point, and the surgeon often meets and is obliged to overcome the prejudice and groundless fear of his patient before administering chloroform—a nervous condition, always to be avoided when any anæsthetic is to be employed. I use the term, "groundless fear," for I believe, from an experience and observation extending over a few years, that, if properly administered, chloroform is the safest, quickest, and, in every sense, the most reliable and the most desirable anæsthetic we possess, and may be safely given under conditions that are generally considered hazardous, if not absolutely fatal.

From a careful study of the effects of chloroform I am convinced its danger lies, not in the drug itself, but in the manner of administering it. I have seen it given in the worst forms of organic heart disease with perfect success, the patient passing off into complete anæsthesia quickly, easily, and quietly.

Eight months ago I was called to see a patient, aged fifteen years, who was suffering from organic heart trouble. I found the boy propped upon pillows, unable to lie in a horizontal position; great dyspnœa; heart laboring to that extent that each pulsation could be readily counted across the room by the shaking of the entire body and the bed upon which he reclined; the cellular tissue everywhere filled to bursting with fluid; the abnormal cavity enormously distended; urine almost entirely suppressed; bowels constipated from the intense pressure upon the sigmoid flexure: decided enlargement of the chest-wall, showing great prominence at the juncture of the fourth rib with the sternum, and the apex impulse three intercostal spaces below normal; the force of the impulse so great that the entire left thorax was lifted with each heart-beat, and carried to the left to such an extent as to be plainly visible from any part of the room, and so strong as to shake the entire body. I detail these symptoms to give a correct idea of the extent of the heart lesion.

Under these conditions I advised tapping as a temporary relief, but the patient absolutely refused to submit to the operation unless an anæsthetic were administered. I consulted my friend, Dr. A. T. Hudson, who has given the subject of anæsthesia much attention, and has contributed, through the Record, several valuable articles on the use of chloroform, and requested him to administer it in this case. A mixture of seventy per cent. chloroform and thirty per cent. alcohol was made, and, after giving a glass of brandy, was administered to the patient in the following manner: The inhaler was held a few inches from the patient's face, and, very slowly and gradually, carried nearer. So gently and carefully was this done that no choking, or sense of suffocation, was experienced, but, instead, the patient passed off easily, quickly, and pleasantly, to complete anæsthesia, without the slightest perceptible impression being made upon his diseased and laboring heart. The abdomen was tapped, and fourteen quarts of fluid removed without the slightest shock or perceptible impression upon the patient. This operation was repeated at intervals three times, with the same success. As tapping gives only temporary relief,

this patient was steadily getting weaker and more œdematous, until it was evident that the end was near. In the hope of giving further relief, we again administered chloroform and drew away a large quantity of fluid. During the administration of the anæsthetic, the pulse slightly quickened and the patient commenced to sing, but the heart continued with its usual firmness.

While the patient was in this exhilarated state the operation was performed. After the removal of the fluid, and after the anæsthetic had been taken away, he moved his position and the heart suddenly stopped; the patient falling over dead. From this case, and others of similar conditions, I am convinced that the danger attending the administration of chloroform lies wholly in the manner of giving it, and, if properly handled, it is not only our quickest and safest, but in all other respects the most desirable anæsthetic we possess. If preceded by sufficient brandy to allay nervousness, and then given so slowly that no sense of suffocation is produced, a few drachms are amply sufficient, and. if care be taken to avoid choking and swallowing of the saliva that had become mixed with the vapor of the drug, little if any nausea will follow. This fact gives chloroform a decided advantage over ether, as one of the chief objections to this drug is the excessive vomiting that usually succeeds its administration. At least two cases have come under my knowledge of a fatal termination after the use of ether, through the uncontrollable vomiting that followed its use as an anæsthetic.

A few days ago I was called to perform a minor surgical operation upon a lady. I found her in a nervous, hysterical condition, through her dread of the anæsthetic. She informed me that two years ago she was anæsthetized for the extraction of some teeth. Ether was used, and it required three hours to bring her sufficiently under the influence of the drug. She complained that the sense of suffocation and strangulation was horrible, while the vomiting that followed—lasting thirty hours—was equally unbearable. A small glass of brandy was given, and chloroform was administered so gently that no sense of choking was experienced, and in eight minutes the patient was ready for the knife. So little of the drug was used that but a few minutes elapsed after completing the operation before the patient opened her eyes and asked when I was going to administer the chloroform, not realizing that it had already been given. No nausea followed, and the patient was able to relish her toast and tea an hour later.

Some months ago I was called into the country to attend a man who had accidentally shot himself in the foot, inflicting a painful wound. A young physician who accompanied me as an assistant attempted to give chloroform by saturating a napkin, placing it in a paper cone, and covering the man's face. The shock was too great, and at the fourth effort at respiration the heart stopped.

By artificial respiration and stimulants the patient was resuscitated, when chloroform was administered, slowly and gradually, as above indicated. Without a struggle or the slightest faltering of the heart the patient passed quickly, easily, and pleasantly, into perfect anæsthesia; the wound was dressed, and the man as quickly and easily returned to consciousness. These are a few of many cases that have convinced me that the only danger in chloroform lies in the first overwhelming shock produced upon the nervous system, especially the cardiac centre, by the sudden administration of the drug. Avoid this shock by giving it slowly, gently, almost imperceptibly, and you rob this grand drug of all its danger and place it where it belongs, at the head of all anæsthetics known to the profession.

Tests for Death.—It is stated by a French authority that a temperature of twenty degrees below the normal standard in the armpit, and twenty-two degrees internally, is a positive proof of cessation of life.

EXSTROPHY OF BLADDER.

By B. MERRILL RICKETS, M.D.,
CINCINNATI, O.

It isn't often that a surgeon is called upon to give relief for exstrophy of the bladder, but where the opportunity does present itself great care should be taken in selecting the appliance or operation to be adopted, as the comfort of the patient is the only consideration.

Extirpation of the bladder is impractical, as is the engrafting of the ureters to the alimentary tract. Not, however, that the latter cannot be done and the subject continue to live, but the consequences of the continuous flow of urine into the gut are more annoying than the malformation.

Of the many devices and operations suggested for this deplorable state of affairs, I have selected the following, with what I look upon as most gratifying results:

M———, nine years of age, male, white, in a very good physical condition, was brought to me in May, 1889, with exstrophy of the bladder and hypospadias. Knowing that all previous operations for exstrophy of the bladder had availed but little, I could offer but slight encouragement, and that only in mitigating the irritability which the exposed mucous membrane of the bladder produced. There was a hernia upon each side, the pubic bone being absent and fibrous tissue being substituted for it. I decided to cover the bladder with integument taken from the abdominal wall, and in that way prevent the mucous membrane from being exposed to the irritation which the clothes had necessarily produced. The opening, through which the bladder protruded, was about two and one-half inches in diameter, allowing the

Fig. 1.

bladder to be returned to the abdominal cavity. This reduction was very easily accomplished when the boy was lying upon his back. On May 9th, under the influence of chloroform, with double pedunculated lateral flaps I covered the exposed bladder, bringing the edges of the flaps in the median line and allowing the cutaneous surface of the inner flaps to form the anterior wall of the cavity containing the bladder. Primary union was secured throughout, and I congratulated myself upon the result; but I found that the small opening through which the drainage-tube passed, at the top, was not and could not be closed. At the same time I made the operation, I made a herniotomy upon the right side. This enabled the gut to be kept in the abdominal cavity. He was discharged at the end of six weeks, but returned to me in the fall, upon my suggestion, to see if the small opening could not be closed, and to relieve the hernia upon the left side. I took another flap from the abdominal wall to cover the small opening, but failed in the attempt, the flap having sloughed. At the same time a herniotomy

was made upon the left side, with most gratifying results. The bladder remains as seen in the photographs, and he experiences the greatest comfort. I am not sure that the small opening has not been a wise provision, for the urinary salts accumulate in great quantities and are washed

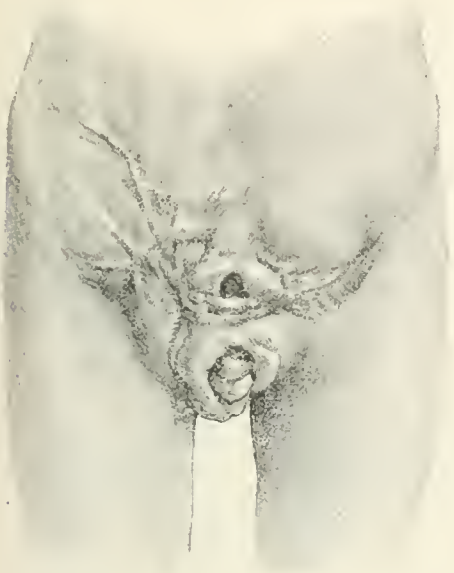

Fig. 2.

out through this opening. I believe that all of these cases should be operated upon in some way, for I am satisfied that the papillomata that so often develop upon the mucous membrane are due to the irritation of the wearing apparel. These papillomata often become malignant, as illustrated in two of the five cases of exstrophy of the bladder that have come under my observation, both of them having died from the effects of carcinoma which developed as the result of the papillomata thus formed.

The Trinidad, 137 Broadway.

PERMANGANATE OF POTASH.

The New Antidote for Morphine Poisoning from a Chemical Point of View.

By L. A. HARDING, B.Sc., Ph D.,

Fergus Falls, Minn.

Every little while the world is startled by some new and useful discovery, and at present the great agitation produced among the medical profession is the discovery of a new supposed antidote for morphine poisoning, namely, permanganate of potash. Not only the medical press, but also the lay press, has taken up the subject and heralded the merits of this wonderful remedy, and many conjectures are formed as to how much practical value is connected with this discovery. It has been known for a long time that the value of permanganate of potash depended only upon its oxidizing power and the freedom with which it is capable of yielding up its oxygen; it has been claimed that the oxygen was held in its nascent state by the permanganate and the phenomena of its oxidizing power simply revolved themselves around this fact; but whether this is a right or erroneous conjecture, the fact remains true that it will yield oxygen to almost all organic substances, with a greater or lesser degree of rapidity, though the decomposition, as indicated by Dr. William Moor, can scarcely be accepted as correct. His theory is as follows:

$$Mn_2K_2O_8 = MO_2 + MKO_4 + KHO + O_2.$$

As will be seen in the decomposition formula (if we may call it such), we have too much oxygen. But this is of no material consequence, matters of more importance demanding our attention.

The observation made by Dr. Moor, to hold a 1 to 2,000 solution in his mouth for fully five minutes without any serious deoxidation of the permanganate of potash, is no criterion of its non-decomposition in the buccal cavity or its connecting parts, for alkaline properties, or an alkalinity of the contents of any cavity favor the non-decomposition, and the decomposition of the permanganate in an alkaline fluid proceeds but very slowly. A test-tube full of water (which contained soluble organic substance) which had been made alkaline, and to which had been added a few drops of solution of permanganate of potash, did not begin to discharge its color for nearly an hour; acid solutions favor the decomposition of the permanganate, and the advice to give an acid of some kind in case of opium poisoning, or in case of any of the salts of morphia, and vinegar being advised by Dr. Moor, is erroneous beyond measure; for do not text books teach, and experience has proven, that acetic acid especially decomposes permanganate?

The action of the permanganate upon albumin and peptone, is a criterion only as far as they go, for the stomach usually contains starches, etc., in addition to albuminoids and peptones; starches especially decompose the permanganate quickly; raw starch has but little action upon it, but boiled starch in any form quickly demands its attention. We may say people do not eat much boiled starch. This idea is, however, quite erroneous, for potatoes and bread contain a large amount of starch, which is only partially acted upon by the alkaline secretion of the mouth during mastication; it lies dormant in the acid fluid of the stomach, but is converted and absorbed in the small intestines; this starch also, while it lies dormant in the stomach quickly attacks the permanganate. Were nothing to interfere, one grain of permanganate of potash would be able to oxidize more than one grain of morphia; so almost anything, if taken in doses large enough, may prove an antidote for morphia. Now suppose the morphine has entered into the circulation, would this still be counteracted by the permanganate? The advocates of this remedy may say yes, for has not Dr. Hitzig, of Halle, proven beyond doubt that morphine which has entered into circulation will return to the stomach, be secreted there by the glands and acted upon by the permanganate as fast as secreted? This is very nice in theory, but in practice, how about the glandular coating of the stomach? Will this not be partially destroyed by the continued contact with the permanganate, and thus secretion likewise be destroyed? We have grave fears of corrosion. As has been mentioned before, deoxidation would quickly take place in acid media; this assumption is without doubt true, for were it not so the permanganate would certainly be absorbed, enter the blood, and cause disturbance there. The latter not being the case, is quite conclusive evidence that oxidation of the lining of the stomach must result, and any poison having entered the circulation is sure to stay there, unless counteracted by physiological antidotes; the proposition to give hypodermic, or intra-renal, injections of the permanganate seems ridiculous, for the blood would soon annihilate it.

We will not attempt to state here, at the present, what changes would occur, but we may easily judge what might happen when we stop to consider the composition of blood, namely fibrin, serum, albumin; and we can draw conclusions as to what the probable results would be; and it seems more ridiculous when we remember that one part of permanganate of potash is soluble in not less than sixteen parts of water, and that at this state of solution it possesses very corrosive properties, and would quickly destroy any oxidizable substance; and as at the rate of dilution at which the doctor uses it by the stomach, namely two grains to the ounce, it would take quite an amount for injection, how foolish to accept this as rational.

The French Academy of Sciences at one time largely used permanganate of potash for flushing the stomach, and suffice it to say, that it required quite a number of douches successively to eject the solution in its characteristic color. This would go to show that it does not require

very much to destroy the permanganate, and we are very sceptical as to accepting any statements made in relation to the permanganate as antidote for morphine in face of the damaging evidence of its chemical behavior.

March 20, 1894.

AN EXPERIMENT WITH PERMANGANATE OF POTASH AS AN ANTIDOTE FOR MORPHINE POISONING.

By JOSEPH M. RECTOR, M.D.,

Jersey City, N. J.

Having read from various sources the experiments of Dr. William Moor, of New York, in which he claims that potassium permanganate may be a possible antidote for morphine poisoning, I beg to submit the following experiments to your notice, and would remark that my results are somewhat to the contrary of those already recorded by the reputable gentleman before mentioned.

On February 4th, in the presence of Dr. E. P. Shelby, Jr., of this city, I gave to a young dog, weighing five pounds, four grains of the sulphate of morphine with the hypodermic needle. Forty seconds after the injection the dog fell to the table with complete loss of muscular power and sphincter relaxation; the pulse was becoming very rapid and weak, so that counting it was impossible; the respiration was rapid and shallow, the "Cheyne-Stokes" type being well marked, the pupils were markedly contracted.

There was complete loss of ocular and plantar reflexes, the dog fell into a quiet sleep, and was aroused only by sudden loud noise or by thoroughly shaking him.

Two minutes after the injection, I gave to the dog five grains of the permanganate of potassium by the mouth.

After forty-five minutes, the dog showed signs of returning consciousness, and in six hours all signs of the action of the morphia were gone, except exceeding nausea, slight cerebral irritation, and in walking his hind legs were dragged as if they were semi-paralyzed, which condition did not pass off until the latter part of the next day.

February 5th, six grains of morphine sulphate were given subcutaneously to a dog weighing twelve pounds.

In seventy-five seconds the severe toxic symptoms of morphine poisoning were present, and in a similar condition to those mentioned previously.

Six minutes after the injection, I administered as an antidote eight grains of the potassium permanganate by the mouth; the results proved to be the same as observed in dog No. 1.

I thought it best at this time to consult some standard authority as regards the amount of morphia which should be required to kill an ordinary-sized dog, and in Professor H. C. Wood's excellent volume entitled, "Therapeutics: its Principles and Practice" (eighth edition), I read the following on page 159:

"In very many cases, if not in the majority, eight to ten grains of the alkaloid [morphia being understood], injected into a dog of moderate size will cause deep sleep, amounting to coma, so that the animal will remain in any position in which he may be placed." According to these instructions, on February 9th, in the presence of Dr. E. P. Shelby, Jr., I gave to the dog No. 2, twelve grains of morphine sulphate subcutaneously. No antidote was given, the dog was left entirely to himself, and complete recovery was noted in thirty-six hours.

On February 10th, I repeated the experiment with another dog, giving him fifteen grains of morphia. No antidote was given, and no medical treatment of any nature adopted, but the dog's recovery was complete.

I have given these experiments to you in response to an article on this subject written by Dr. Glenn Andrews, and published in the Medical Record of March 10, 1894. My own investigations, with those of Dr. Andrews, seem to point to the fact that such other experiments as have been previously noted and described, were undertaken with such small doses of morphine sulphate that no harm whatever would have happened to the animals, were such doses not followed by any antidote or other medical aid.

It is not my purpose to decry the experiments on the discovery of Dr. William Moor and his associates, but to bring to notice the possible fact that such investigations were too limited in numbers and the results too meagre in positive facts, for any belief in the efficacy of permanganate of potash as the possible antidote for morphine poisoning to be established.

100 Grand Street.

Clinical Department.

BLOODLESS AMPUTATION AT THE HIP-JOINT.[1]

By DANIEL STROCK, M.D.,

Surgeon to the Cooper Hospital; Lecturer on Dietetics in New Jersey Training School for Nurses, Camden, N. J.; Surgeon Sixth Regiment, N. G. N. J.

About half-past six of the evening of January 25th, F. T——, a railroad employee, was carried to the Cooper Hospital suffering with a crushed thigh. The leg had been completely severed from the body at a point just above the knee, the femur was crushed in its lower third, and the soft parts crushed and lacerated up to within an inch of the pelvis. The destruction of tissue can be better understood when it is known that before I could utilize the skin necessary for the flaps, I was compelled to dissect off about ten square inches of its connective tissue to remove the sand and cinders that firmly adhered to it. Also, at least one fourth of the edges of the flaps had to be refreshed, to remove the devitalized portion concerned in the crush.

What remained of the limb was removed at the hip-joint, and the interest in the operation centres in the manner of its performance, which was by what is known as the Wyeth bloodless method. This consists in the application of a rubber constrictor in such manner as to occlude every vessel at the level of the hip-joint, and "permitting the disarticulation to be completed and the vessels secured before the tourniquet is removed."

The technique is as follows: Two large pins are employed, which are eight or ten inches long and three-sixteenths of an inch in diameter, one of which is introduced one inch below the anterior superior spine of the ilium, and slightly to the inner side of this prominence, and is made to traverse superficially the muscles and fascia on the outer side of the hip, emerging on a level with, and about three inches from, the point of entrance. The point of the second needle is made to enter one inch below the level of the crotch, internally to the saphenous opening, and passing through the adductors comes out an inch below the tuber ischii. A piece of strong rubber tubing, or band, is then wrapped several times tightly around the thigh, above the fixation-pins, and securely tied. It is evident that this procedure secures all the vessels involved in the incisions, and the pins render it impossible for the tourniquet to slip; thus justifying the originator's claim that by this method it is possible to always perform this formidable operation without the loss of more than an ounce or two of blood. My own experience coincides with this statement. No blood whatever was lost from the vessels above the tourniquet in my case, and I feel convinced, if the constricting band is properly and tightly applied, that serious hemorrhage need never occur. Death followed within an hour after the completion of the operation.

Professor Wyeth has reported forty-one cases of amputation at the hip-joint by this method, occurring in all parts of the United States, and in every instance the amount of blood lost has been almost nil.

When we compare the simplicity and ease of this

[1] Read before the Camden (N. J.) County Medical Society, February 13, 1894.

method with the formidable and dangerous means formerly employed to control hemorrhage during hip-joint amputations, such as pressure on the aorta through the abdominal wall, or by means of an instrument in the rectum, ligation of the femoral artery, or digital pressure upon that vessel, we can readily perceive that a distinct advance has been made.

Professor Wyeth's claim that he is the originator of this method of controlling hemorrhage in this operation is disputed; and it is asserted that the idea has been advocated or put in practice by others. Be that as it may, the fact remains that he has been instrumental in calling attention to the utility of this procedure, and has popularized it to such an extent that it is doubtful if any other method is now resorted to in hip-joint amputations.

The man who rescues an obsolete operation from oblivion, and demonstrates its worth, or adds to its technique details that render its performance safer and more practical, should be accorded all the credit that is his due.

818 Federal Street, Camden, N. J.

A NEW PROOF THAT BERIBERI IS DUE TO CARBONIC POISONING.

By A. S. ASHMEAD, M.D.,

NEW YORK.

M. T.——, aged twenty-seven, a native of Bungo, for five years previous to 1888, while residing in Tokio, had beriberi every year; the disease, as usual, began in spring, and lasted until fall. In September of the fifth year, moxæ were applied to each side of the second dorsal vertebra, about three inches from the spine, three on each side; as fast as one burnt out, another one was put to the same spot, until three had been applied to the place. This was done three days in succession. In the next year, although the patient remained in Tokio, the disease did not return, and it has not reappeared since.

It has been for twenty years, that is, since my sojourn in Japan, my opinion that beriberi is due to carbonic poison. I have published in the medical papers several articles in which I endeavored to explain my idea, and to prove the truth of my theory. It has been my good fortune to discover many facts which bore it out with singular clearness, and almost evidence. But none is more striking than the case which I have just related. The moxæ, applied as I have described, directly affect the nerves of respiration, the pneumogastric, and the phrenic. The function of respiration is to introduce oxygen, and to eliminate carbonic gases. In beriberi, all these nerves are, in a measure, paralyzed, or numbed by the carbonic poison, and consequently the muscles of respiration; the direct ones which elevate the ribs, the diaphragm, and the indirect muscles, which fix the shoulders, and help the first category to act. The nerves of respiration are the pneumogastric, with its inferior motor branches, and the phrenic nerves, motors of the diaphragm. Now, the severe irritation produced by the moxæ stimulates these nerves to a degree of activity which produces deeper inspiration and expiration of the lungs, which can only be powers conducive to the introduction of oxygen and the expulsion of the poison, which in my opinion is the true cause of beriberi. On the heart the influence of the moxæ is an indirect one, because the pneumogastric nerve is the restraining nerve of the heart, its driving power being due to the sympathetic. In no other way than in the way I have described, is it conceivable that the moxæ can exercise a curative effect on the beriberi disease. If we admit that beriberi is due to carbonic poison, everything becomes clear; if not, the effect of the moxæ is inexplicable.

I have one word to add. It may be said that one swallow does not make a spring, and that one success of the moxæ does not prove that moxæ are always successful. But the fact is that, next to the altitudinal treatment, whose good effect can also be best explained by admitting the carbonic origin of the disease, no other treatment can report such frequent, such continuous successes as that of the moxæ.

SUPPURATION OF THE MIDDLE EAR DUE TO A COFFEE BEAN IN THE NOSE.

By M. D. LEDERMAN, M.D.,

NEW YORK.

ASSISTANT SURGEON, MANHATTAN EYE AND EAR HOSPITAL; INSTRUCTOR IN LARYNGOLOGY, NEW YORK POLYCLINIC; ASSISTANT LARYNGOLOGIST AND OTOLOGIST, MT. SINAI HOSPITAL DISPENSARY.

Clinical experience offers undoubted evidence that the majority of aural affections are traceable to some previously existing lesion in the nose or naso-pharynx. The essence of modern literature fully substantiates the above seemingly sweeping assertion, and personal observation certainly corroborates its importance. The number of chronic catarrhal otitis cases which have passed through sieges of politzerization, catheterization, and counter irritation, without having the immediate cause of their trouble eliminated, is indeed surprising.

It is not sufficient to test the relative aërial and bone conduction by the various methods which are recommended, and then be satisfied that the existing ratio substantiates the diagnosis of chronic aural catarrh. We must ascertain its origin, and when the initiative lesion is discovered, we can then more knowingly and successfully treat the train of symptoms which arise.

Without a doubt, chronic hypertrophic rhinitis is the most frequent causation of middle ear disease. Nasal obstruction retards a proper aëration of the Eustachian tubes and middle ear, thus creating a rarefaction, which permits a dilatation of the blood-vessels of the lining mucous membrane, giving rise to usual symptoms. We should, therefore, in such instances, direct our efforts toward re establishing an equilibrium of atmospheric pressure, by removing the hindrance to normal respiration. We cannot lay too much stress upon this subject, for many cases of middle ear catarrh remain unimproved for want of proper appreciation of the exciting factor. Again, unnecessary interference with the sensitive nasal mucous membrane may incite an atrophic process, which is not only a distressing feature *per se*, but may affect the continuous structures of the adjacent cavities as well. We must arrive at a happy mean, and avoid the possibility of becoming too heroic in our methods.

The history of my case demonstrates the intimate relationship existing between the nose and ear.

The patient, Nettie G——, aged three years, had a running ear for two months. About three months previous to my seeing the little one, the mother noticed that the child constantly picked and rubbed the nose. The parent thought she had worms, so anthelmintics were given to eradicate the parasites, without, however, relieving the constant nose picking. Prolonged elevation of temperature existed. Unilateral nasal discharge appeared, which caused an eczema of the upper lip by its incessant flow. The little girl's nose was treated by the family physician, who prescribed a cleansing spray, and diagnosed the affection as a purulent catarrh. About a month after the nasal symptoms developed, severe pain was complained of in the left ear, which deprived the child of sleep for three or four nights. Hot-water douching generated a copious discharge of pus from the ear, which greatly relieved the distressing pain, and brought about a fall of temperature. Suppuration continued until I saw the patient, two months after its first manifestation. Antiseptic douches had been diligently used, but they did not control the offensive excretion.

Inspection revealed the left auditory canal filled with foul smelling pus, together with an eczema of the auricle. On cleansing the meatus, the drum membrane was visible, presenting a perforation of the posterior inferior quadrant. A muco purulent secretion filled the left nasal chamber. Being unilateral, and recalling the previous symptoms, the thought of foreign body arose. On ex-

amining the nose, could detect some obstruction in the middle meatus, but could not appreciate its nature. The probe met with resistance unlike that felt from coming in contact with the usual hypertrophies. Introducing the tip of a Pomeroy's ear syringe, filled with a warmed boric-acid solution, into the right nostril, I exerted some little pressure and was rewarded by finding a coffee bean in the fluid returning through the left or obstructed side. The mother then remembered that the child was in the habit of playing with coffee beans, and one readily realized how frequently children introduce foreign bodies into accessible cavities.

An antiseptic nasal spray, together with a suitable cleanser for the ear, was prescribed. Four days later the young one returned, without the slightest trace of pus in the ear. The nasal discharge was not quite clear, but in a week it had assumed a normal appearance. The hearing was not materially lowered at any time, but the general condition of the patient responded promptly to the treatment. The almost immediate cessation of the aural discharge after the removal of the irritating factor, vividly pictures the importance of carefully examining the nose and naso-pharynx in all cases of aural disturbances.

TREATMENT OF CHRONIC URETHRITIS.

By JOHN McGRATH, M.D.,

ASSISTANT SURGEON, ROOSEVELT HOSPITAL, OUT-PATIENT DEPARTMENT.

From results obtained in the treatment of twelve consecutive cases of chronic urethritis I am induced to present the following facts:

In the first place these were ordinary chronic cases, all presenting posterior as well as anterior urethritis. The urine showed the usual cloudiness and clap-threads, varying from foul smelling, turbid urine to that fairly clear with numerous threads present; the two-glass test being employed. The urethral discharge was in most cases slight and present especially in the morning, with the usual history of exacerbations after intercourse or indulgence in alcohol. In duration they varied from eight months to six years, the average time being between two and three years; they had all received treatment, more or less, during this time; one of the cases having been treated continuously for six months, without beneficial effect, by one of the most enthusiastic advocates of the deep injection of strong solutions of nitrate of silver, bleeding and excessive pain having often followed the injection of the strongest solutions.

Several of the cases had been complicated by one or more attacks of epididymitis. In three there were loose anterior strictures within few inches of the meatus. In none was it necessary to divide the meatus; so that these might be considered fair examples of the ordinary chronic urethritis or gleet.

The treatment consists in the use of a large quantity of a weak solution of nitrate of silver, used in the beginning every day. At first an injection of from twelve to fourteen ounces of a quarter-of-a-grain-to-the-ounce solution is used. This is introduced into the bladder through a soft-rubber catheter of small size, a No. 8 French with large bore, lubricated with glycerine, being convenient and easy of introduction; through this the solution is allowed to flow from an ordinary glass irrigating jar with rubber tube attached; the catheter is then withdrawn and immediately thereafter the patient is allowed to empty the bladder, thus washing out the bladder and whole length of the urethra. This solution is injected every day until the urine shows marked improvement, which is usually at the end of one week or ten days, and after that at intervals of two or three days. The strength of the solution need not be increased to more than a half-grain to the ounce, when the quantity of the solution may be somewhat reduced, say to eight or ten ounces.

In those cases that were complicated by stricture in the anterior urethra, a sound was introduced directly before the injection, and this continued until stricture was dilated up to usually No. 30 French. The average time occupied in obtaining the urine absolutely clear and free from threads was about one month, some in three weeks, and some going for two months. They all showed marked improvement from the start. During the treatment the patients abstained from intercourse and alcohol. The treatment for posterior urethritis, recommended by many, of injection by means of the Ultzmann syringe of small quantities of solution of nitrate of silver of gradually increasing strength, even up to twenty-five grains to the ounce, does not yield nearly such satisfactory results in this space of time, and besides often causes the patient much pain and discomfort, and even bleeding after the injections.

In some cases it would seem that an attack of epididymitis was due directly to the use of these strong solutions. It would seem that these stronger solutions were used in many cases where there was no indication for them, and where they oftentimes do much more harm than good; whereas, the use of the weak solution seems to be simple, safe, and adequate to bring about a satisfactory result in a comparatively short time without causing the patient any considerable pain or discomfort. While the number of cases may not be large enough to allow of any positive conclusions, yet the results have been invariably so satisfactory that I offer the result of my experience, and think that further practice might warrant this method of treatment in many cases of chronic urethritis which are now treated by the use of small quantities of much stronger solutions of nitrate of silver.

The act of urination immediately before introduction of the catheter cleanses the urethra sufficiently, and with usual precautions for clean instruments there seems to be no danger of causing irritation or infection.

275 Lexington Avenue.

GONORRHŒA AT THE AGE OF ONE HUNDRED AND THREE.

By A. E. ISAACS, M.D.,

NEW YORK.

INSTRUCTOR IN SURGERY, UNIVERSITY OF THE CITY OF NEW YORK, MEDICAL DEPARTMENT; VISITING SURGEON, BETH ISRAEL HOSPITAL.

The interest that may attach to the case presented herewith will be by reason of the advanced age of the patient. It is exceptional enough to meet a man who has passed his one hundredth year, but to find a man at that age suffering from an acute attack of gonorrhœa or chancroids is still more exceptional.

Some doubt may be entertained as to the correctness of the age given, but his general appearance, his open frankness in giving all particulars, and the absence of any apparent motive for falsification, go to confirm it, and a severe cross examination failed to alter any of his statements.

Although no special time is given for the decadence of the sexual functions in the male, the general impression seems to be that the sexual desire is on the wane and disappears long before the allotted "three score years and ten." Yet here is a man, aged one hundred and three, who "feels that he needs it," and in getting it is unfortunate enough to contract chancroids at the age of one hundred, and gonorrhœa at the age of one hundred and three.

In the following history the facts bearing on his age and manner of contracting this attack are given somewhat in detail, because of the possibility of doubt of the former, and to illustrate his state of mind in regard to the latter.

A. C ——, aged one hundred and three, native of Ireland, occupation formerly longshoreman, at present none, presented himself on January 30, 1894, at the Dispensary of the University Medical College, for treatment.

Examination revealed a copious characteristic gonor-

rhœal discharge, which he stated was only of a few days' duration. Genitals well developed and showing no signs of senility. Complains of painful urination; general health otherwise fair.

In answer to questions he stated as follows, given partially in his own words:

"Didn't know more than that chair about a woman" till fifty years of age, because "at home you dasn't." Then he married and shortly after left Ireland. Spent five years in the mountains of Wales, and forty-eight years ago came to this country. His oldest living son is now fifty years, and his youngest thirty-three years of age. His father lived to be one hundred and five, and his mother ninety-five years of age. His second wife died twelve years ago. This is the fourth attack of venereal trouble he has had since—the previous attack, three years ago, was chancroids, which was also treated at the University Dispensary, and of which he got well in about two weeks.

He feels that he needs a woman. He contracted this gonorrhœa from a woman whom he had befriended and assisted; her husband had died some six months previously. She frequently came to him complaining that she had no bread for her children, and he used to "throw" her fifteen or twenty five cents when he had it, because so long as he had a few cents in his pocket, he could not see her or her children go hungry. She used to come in and drink tea and take a bite, and play and joke, till it came to this that she seduced him. "That's the way she paid me off for helping her children, and I think it will be the end of me."

The following question suggests itself in connection with this case: Could there be any causative relation between the late appearance of sexual activity and its persistence to this advanced age?

168 Henry Street.

Progress of Medical Science.

Metastasis or Shifting Elimination as a Factor in Certain Skin Inflammations.—Dr. Walsh believes that certain forms of dermatitis connected with abnormal conditions of the blood may be directly due to the elimination of irritating substances. Uric acid and the scarlatinal virus may be regarded as types of unusual substances circulating in the blood which are capable of causing inflammation of one or more of the channels of elimination. Uric acid in excess being highly damaging to the epithelium of excretory organs, is able to produce, besides dyspepsia, nephritis, bronchitis, some forms of dermatitis. Metastasis is often a marked feature in gout, a typical eczema sometimes occurring during an acute gouty attack, and disappearing under treatment with colchicum. The skin trouble may alternate with bronchitis and asthma, or with diarrhœa. The scarlatinal poison, like uric acid, acts as an irritant upon the epithelium of excretory organs, and may cause dermatitis in addition to nephritis and inflammations of the respiratory and alimentary tracts. Dr. Walsh holds that if uric acid be excreted by the bowel, diarrhœa results; by the skin, dermatitis; by the kidney, nephritis; by the lung, bronchitis—these various inflammations being the result of excretory inflammation.—*The American Journal of the Medical Sciences.*

Congenital Hydronephrosis Cured by Nephrectomy.—Dr. Adler has reported the case of a child that, at the age of two years, began to show evidences of abdominal pain and distention, particularly upon the left side. After medicinal measures had been exhausted without avail, an exploratory puncture was made, and showed the swelling to be due to an accumulation of fluid containing small amounts of urea. An incision in the linea alba below the umbilicus disclosed the presence of a tumor occupying almost the entire abdominal cavity, and compressing the intestines into a small compass beneath the liver. The wall of the sac was sutured to the abdominal wound, then opened, and a portion excised. The tissue removed proved to be renal structure. Nearly a pint and a half of pale, clear fluid containing a moderate amount of urea and a small proportion of albumin, was evacuated. After the operation the child was in good condition, and the tumor slowly but gradually diminished in size, although the fistula persisted, and urine was passed but seldom (about every second day) and in small quantities, by the natural channels. Nephrectomy was not undertaken at this time, from a fear that the right kidney might not be in good condition. At a later date, however, the right kidney being detected in its proper position and not appearing of unusual size, and, further, the urine passed by the urethra being clear and without morbid constituents, while that from the fistula was turbid, albuminous, and contained renal epithelium, nephrectomy was determined upon, and with some difficulty performed. The subsequent behavior of the case was entirely satisfactory, and at the end of four weeks the wound had closed and presented but a small granulating surface. The urine was now passed by the natural channels in larger amount than before, and was of normal quality. The general condition of the child was also improved.—*Medical News*, March 24, 1894.

How Animals Practice Medicine.—It is known that animals not only treat themselves, but that they also treat each other. Animals get rid of their parasites by using dust, mud, clay, etc. When a dog has lost its appetite, it eats that species of grass known as dog grass, which acts as an emetic and a purgative. When cats are ill it is a matter of common observation that they eat grass. Animals suffering from chronic rheumatism always keep, as far as possible, in the sun. If a chimpanzee be wounded it stops the blood by placing its hands on the wound, or by dressing it with leaves and grass. A dog, on being stung in the muzzle by a viper, was observed to plunge its head repeatedly for several days in running water. Animals that have been injured in the eyes avoid the light and heat. It is also very generally known that when animals are ill they abstain from food; in fact many times this is the only way the farmer knows that his horses and cattle are ill.

Congenital Absence of Both Radii.—Dr. Krönig exhibited before the Leipzig Obstetrical Society a child, aged fourteen days, with congenital absence of both radii. There was a moderate amount of hydrocephalus, but no other disease or deformity beyond the forearms. The most remarkable feature in the case was the presence of the thumbs and the perfect development of the hands. The supinator longus was powerfully developed and inserted into the middle of the ulna. The carpal bones seemed to be perfect. The ulna was strongly bent to the radial side. There are forty-five recorded cases of congenital absence of the radius, and in twenty one the defect was bilateral. In only two were the thumb and first metacarpal bone well developed. In the great majority of cases the child was both premature and stillborn, and it seldom lived many weeks. Nearly always other defects were present in different parts of the body. In Krönig's case, contrary to the rule, the elbow and carpal articulations were freely movable.—*Centralblatt für Gynækologie.*

Fees for Graduation in Medicine in France.—By decree dated February 14, 1894, the following fees will be payable by all candidates for the M.D. degree in a French Medical Faculty after November 1, 1895: Sixteen "inscriptions" at 32.50 francs, including library subscriptions, 520 francs. Practical classes, payable quarterly for four years, 160 francs: first year, 60 francs; second, 40; third, 40; fourth, 20. Seven examinations at 30 francs, 210 francs. Seven certificates of having passed these examinations at 25 francs, 175 francs; thesis, 100 francs: certificate for thesis, 40 francs: diploma, 100 francs. The total amount payable for the degree is, therefore, 1,305 francs, *i.e.*, about two hundred and sixty dollars in our money.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, April 14, 1894.

TUBERCULOSIS AND ANIMAL INDUSTRY.

AN important bulletin on "Tuberculosis in Relation to Animal Industry and Public Health" has recently been prepared by Professor James Law, and issued from the Cornell Agricultural Experiment Station. Many of the facts given are familiar enough to medical readers, but many new and important data have been collected, and the whole subject is treated in a very thorough and complete manner.

Accurate statistics as to the prevalence of tuberculosis in American herds are wanting, but the European figures are suggestive. Thus tuberculous cattle are said to number: In Bavaria, 0.225 per cent. (Goring); in Augsburg, 0.26 per cent. (Adam); in Baden, 0.2 per cent. (Lydtin); in France, 0.5 per cent. (Arloing); in Belgium, 0.4 per cent. (Van Hertsen); in Paris, six per cent. (Friedberger and Fröhner); in Holland, twenty per cent. (Schmidt); in Pommerania and Bomberg, fifty per cent. (Schanz, Albrecht); at Hildesheim, Hanover, sixty to seventy per cent. (Haarstick); in Leipsic, twenty per cent. (Rieck); in Edinburgh, twenty-six per cent. (Cope, McFadyean). American figures given by the Bureau of Animal Industry are for Baltimore (mostly cows) 2.5 to 3.5 per cent., and for the packing centres (among 2,273,547. mostly steers) 0.02 per cent.

In a large aggregate number of German abattoirs cows suffered in the ratio of 6.9 per cent.; oxen, 3.6 per cent.; bulls, 2.6 per cent.; and calves and yearlings, 1 per cent. In Leipsic, tuberculous cows were 26 per cent.; oxen, 19.5 per cent.; bulls, 15.4 per cent.; and calves, 9.3 per cent.

In infected breeding and dairy herds in New York, consisting largely of mature cows, Professor Law has found a maximum of ninety-eight per cent. and a minimum of five per cent.

Professor Law gives an account of the nature, causes, and symptoms of tuberculosis in cattle which is interesting, more especially to stock-breeders and veterinarians. He describes the methods of diagnosis and discusses especially the tuberculin test. The objections to this test are stated *seriatim*, and are very fully answered. He sums up his views thus:

"The tuberculin test aggravates existing tuberculosis, and is, therefore, unwarrantable for use on man or on cattle that are to be kept alive: it is, however, the only known means of detecting many occult cases of tuberculosis, and is, therefore, indispensable in any systematic effort to stamp out the disease by the purchase and slaughter of every tuberculous animal."

He next discusses the danger to the human family from using the meat and milk of tuberculous animals. He shows that the red muscle of infected animals is rarely infecting, yet is not entirely free from danger. In pigs the muscle-tissue itself may be tuberculous, and in cattle the roasts and steaks contain intramuscular lymphatics which may be tuberculous. Hence the raw meat is certainly a possible source of danger. We are not told how completely cooking destroys the bacilli. Milk is more to be dreaded than meat, because the udder is often the seat of tuberculosis. While milk is not dangerous when the udder is not involved, experiments show that we cannot always tell in the living animal whether this gland has been attacked or not. Hence Professor Law's conclusion is that a tuberculous animal, however slightly infected, is always a source of danger.

Although the cow is so undoubtedly a source of danger to man, few cases which give demonstrable evidence of direct infection have yet been reported.

In the practice of Dr. Stang, of Amorback, a well-developed five-year-old boy, from sound parents, whose ancestors on both male and female sides were free from hereditary taint, succumbed, after a few weeks' illness, with acute miliary tuberculosis of the lungs and enormously enlarged mesenteric glands. A short time before the parents had their family cow killed, and found her the victim of advanced pulmonary tuberculosis (Lydtin).

Dr. Demme records the cases of four infants in the Child's Hospital at Berne, the issue of sound parents, without any tuberculous ancestry, that died of intestinal and mesenteric tuberculosis as the result of feeding on the unsterilized milk of tuberculous cows. These were the only cases in which he was able to exclude the possibility of other causes for the disease, but in these he was satisfied that the milk was alone to blame.

A gentleman of North Hadley, Mass., a graduate of the Massachusetts Agricultural College, has stated that his only child, a strong, vigorous boy, aged one year and a half, went to an uncle's for one week and drank the milk of a cow which was shortly after condemned and killed in a state of generalized tuberculosis. In six weeks the child was noticeably falling off, and in three months he died, a mere skeleton, with tuberculosis of the abdomen. The father could trace no tuberculosis among his near ancestors, but the mother's father and uncle had both died of it. She remains in excellent health.

Professor Law makes a strong and a novel point with regard to the use of the meat or milk of slightly infected animals. He contends that every animal which has tuberculosis is more or less poisoned by the secretions of the bacilli. Hence those who eat the flesh or drink the milk are continually receiving small doses of "tuberculin." Now, if this person has no tuberculosis, the ingestion of this poison may do no harm, but if there is any latent focus of this disease, the use of the "poisoned" food stirs up the latent disease and does serious harm. This view, it will be seen, is directly contrary to that adopted when the tuberculin was first discovered. Nor is it yet certain that tuberculin properly used may not do good. Of the fact that it may do harm, however, there is no doubt.

The logical conclusion reached by Professor Law is

that the meat and milk of tuberculous animals, however slightly infected, are always a source of danger, and should be condemned.

Two enormous tasks are naturally presented to the State and to economists for solution. One is that of exterminating all tuberculosis by means of test examinations of the animals; the other is the thorough inspection at the abattoirs of every animal slaughtered for food, and the rejection of all animals which are in the slightest degree infected.

The difficulty and expense attending such work will be at first very great. But it seems to us that the course to be pursued is a plain one. Tuberculosis kills one twelfth of the population and maims many more. The most patent and serious source of danger is in the animals which supply us with milk and meat. We do not hesitate to spend millions on a navy and army which are to be used only against possible future enemies. Why should we hesitate to spend still more on an enemy which is real and which is constantly assailing us?

OUR CABLED DESPATCHES FROM ROME.

In noting from time to time the progress which has been made in American Medical Journalism we have often taken occasion to point out those well-known relations between demand and supply which form the basis of every successful business enterprise. If, in this connection, we felicitate ourselves in meeting the requirements of different situations as they present themselves, we may perhaps be excused for so doing in the confession of a reasonable enthusiasm for good and useful work successfully accomplished. The many kind words and hearty congratulations we have received concerning our recent cable despatches from Rome abundantly prove that our readers are keenly alive to the value and importance of prompt and accurate reports of important gatherings in far-away countries. The account of the International Congress in our issue of last week was not only the fullest cabled report of a scientific meeting ever published in this country, but it was the only one of the sessions at Rome which has yet appeared in any medical or lay journal. In times gone by, when it was the boast of some of the larger medical journals that the telegraph at home and the cable abroad would be freely used for promptly gathering information, the Medical Record strove, and not vainly either, to take the lead. Since then it has persistently followed this course in spite of the enormous expense which was often necessary to that end. Although at present standing virtually alone in the advocacy of such a policy, and in the execution of such plans, we are still confident that, in spite of the outlay, it pays in more ways than one to keep fully abreast to the truer interests and higher aims of advancing journalism. We have on that score such abundant evidence of the appreciation of our thousands of readers at home and abroad, that we are more than encouraged to continue in our present course, and vindicate still more effectually our claim to cosmopolitanism in everything which pertains to the editorial management of the Medical Record. By so doing we are not in any way interfering with the best interests of the hundreds of local journals that have a flourishing existence in this country and Canada. These periodicals, we are glad to learn, are receiving the substantial support they deserve. It is eminently proper that the profession in such localities should liberally encourage their own journals, as no other forms of publication can or should replace them. They are as much necessities as are the leading metropolitan weeklies. Each progressive medical man appreciates the need of a home journal to keep him informed of the doings of his particular locality, but he cannot neglect the opportunities of being in touch with the great outside medical world through the weekly visitor from the great medical and commercial centre. We trust that the Medical Record will continue to deserve the kind congratulations of its many friends, and its best answers to those so recently given are its past history and its hopeful future.

SMALL POX AND ANTISEPTIC VACCINATION.

The prevalence of small-pox in Chicago, New England, New York, and other cities is only relatively great. For the week ending March 24th the number of deaths from this disease in forty of our larger cities was 15, and this means less than a total of 100 cases. Still, the disease appears to be increasing in some cities, and its presence at all times excites especial alarm.

One of the curious features incidental to this recrudescence of variola is an unusual activity among anti-vaccinationists. They have been working especially hard in Boston, as we learn from the *Boston Medical and Surgical Journal*. At least four hearings have been given by the Legislative Committee on Public Health regarding the compulsory vaccination law. Some of the gentlemen who do not believe in vaccination devoted themselves to rehearsing the same old arguments and statistics that have been in evidence since the century began. Others presented a number of cases illustrating the danger of vaccination. We do not know whether or not lurid pictures of the horrors of syphilis and leprosy were presented; they probably were; but if the propagandists simply limited themselves to a description of the ordinary accidents and sequelæ of vaccination they might have made something of a case. This case, however, would be not against vaccination but against a careless performance of the operation. There is no donbt that some physicians still neglect to vaccinate aseptically. If they do, it is most reprehensible. In vaccinating a child the skin should be carefully sterilized, the hands of the operator clean, his instruments aseptic, and the water used for moistening the quill should be boiled. The wound should finally be carefully protected. If all this be done, cases of erysipelas or other forms of infection will be very rare.

The Practice of Medicine in Maine.—A correspondent sends us the following clipping from the Rockland (Me.) *Courier Gazette*, concerning the social and financial status of the physician in one of the small island towns: "There is talk of getting up a time to raise money to help keep our doctor here another year. He cannot stay on what practice he gets, and we cannot afford to have him go. The most of us know what it is to go to the main and Carver's Harbor for doctors. Let's wake up and get up a good time, and raise what money we can for the good cause!"

News of the Week.

A Professional Centenarian.—Dr. E. G. Roberts, of Fair Haven, Vt., writes: "In a Welsh newspaper of recent date it was announced that Mr. W. Reynold Salmon, M R.C.S., of Penllwyn Court, Pontfaen, S. Wales, had attained his one hundred and fourth birthday on March 16, 1894. It states that there are indisputable proofs of his having been born on March 16, 1790."

The International Congress.—The following was received by cable too late to be used in our previous issue: The next meeting of the International Medical Congress will be held in Russia, the choice between Petersburg and Moscow to be decided by the Czar. Kocher's address, delivered Wednesday, was on gunshot injuries, but Cajal's address was not delivered. Dr. Juhel Renoy, who died recently in Paris from typhoid fever, was to have read a paper at the Congress on the value of cold baths in the treatment of this affection. Another physician attending the Congress died suddenly in Rome, a few days before the meeting, while riding in an open carriage.

Hospital Saturday and Sunday Fund.—Up to date the sum received for this purpose is $58,400.

Migraine.—In our issue of March 24th, the dose is spoken of as 1.1 gr., which quantity contains 0.09 gr. of caffeine. The "gr." in this instance naturally refers to grammes, as anyone, we think, would see at a glance, but since the question has been raised we wish to call attention to it.—Ed.

A Bill to License Quacks.—The New York Medico-Legal Society, says *The Medical Standard,* has some decidedly queer legal members. One of these, ex-Judge Abram Daly, recently appeared in advocacy of a bill emasculating the Medical Practice Act in favor of "Christian scientists," clairvoyants, etc. He advanced the following "reasons:" "If 'Christian science' did not cure, at least it did no injury. It was as unjust for the Legislature to say how a man should be cured, as it was for a railroad company to say that a man should travel on their road. He said that one daughter of his had been cured by a clairvoyant, who had diagnosed her case after a physician had failed. He mentioned another case, of a daughter who had died because of an incompetent physician. He was in favor of the bill because of the freedom of practice it accorded. The fighting among doctors was such that it was necessary that more freedom be had." We presume it is the same gentleman who has had introduced into the Assembly a bill providing that any person may freely contract for the services of whomsoever he considers competent to alleviate suffering or prevent or heal disease, and that it shall be lawful for persons so employed to attend, treat, nurse, and endeavor to heal the employing patient, and receive compensation therefor, subject to the laws of the State relative to malpractice. It is in the interest of "Christian science," clairvoyants, etc.

Physicians' and Surgeons' Instruments are Mechanical Implements.—The Board of U. S. General Appraisers at New York hold, in a decision of theirs rendered December 30, 1893, that, following a fair construction of the language of the Supreme Court, instruments used by the physicians and surgeons of a hospital, for the purpose of carrying on their professions, are mechanical implements—implements for carrying on the professions of medicine and surgery—and cannot be classed as either philosophical or scientific instruments or apparatus, for the assessment of duties, when imported, and cannot be admitted free.

The Sentiment in Favor of the Bill for Establishing a Bureau of Public Health grows rapidly.—We have indeed seen no unfavorable criticism of the bill.

Agnew Memorial Hospital.—The widow of the late Professor D. Hays Agnew has given $25,000 to the University of Pennsylvania. The money will be used in erecting an extension to the hospital.

Beaumont Hospital Medical College, it is reported, will consolidate with the St. Louis College of Physicians and Surgeons.

Mütter Lectureship of the College of Physicians of Philadelphia.—The next course of ten lectures, under the bequest of the late Professor Thomas Dent Mütter, M.D., LL.D., "On Some Point or Points Connected with Surgical Pathology," will be delivered in the winter of 1896–97, before the College of Physicians of Philadelphia. The compensation is $600. The appointment is open to the profession at large. Applications, stating subjects of proposed lectures, must be made before July 1, 1894, to William Hunt, M.D., Chairman of Committee on the Mütter Museum, Northeast corner Thirteenth and Locust Streets, Philadelphia, Pa.

A Substance of Extraordinary Antiseptic powers, yet practically innocuous, has recently been described by Hans Aronson (*Münch. Med. Woch.*, March 20, 1894). He calls it paraform and says that it is a combination of several molecules of formaldehyde. It is a polymerized formaldehyde, and an insoluble powder, having sixteen times the antiseptic power of Beta-napthol. Unfortunately it is generally found that some enterprising German drug firm is behind all these wonderful antiseptics.

An Artificial Horseback Ride.—An ingenious Londoner has invented a saddle arrangement which gives to the person astride it all the motions of a horseback ride. By varying the adjustment, one gets a trot, a gallop, or a walk.

The Approaching Congress of Physicians and Surgeons bids fair to be interesting. The programme of the public meetings embraces a number of subjects of general interest, and the discussions will be participated in by men from whom the profession is usually glad to hear. National meetings of this kind, in which the leaders of medical thought are fairly represented, ought to have, one would think, a beneficent influence upon the general tone of the profession. No junketing, no politics, no sectionalism, but only earnest interchange of thought and experience are good, even somewhat novel, bases upon which to erect a congress in which all physicians shall feel an interest.

Cremation.—Such has been the growth of popular opinion in favor of the sudden disposition of the dead by heat that there are now in the country eighteen incorporated cremation societies, and during the past ten years about three thousand cremations have taken place.

The Fourth Dermatological Congress will be held at Breslau, Germany, on May 14th, 15th, and 16th. An invitation has been extended to all members of the American Dermatological Association.

Cholera in Constantinople.—Cholera of a most malignant type has become so prevalent throughout the city as to cause general alarm. The disease has hitherto been confined to the poorer districts. The Greek legation has been removed to Therapia, about seven miles distant, and it is probable that other foreign representatives will seek temporary quarters outside the city. The Turkish authorities are taking active measures to prevent the further spread of the disease.

Dr. Newton Whitehead, of 218 East Forty eighth Street, whose advertising cards have been so freely and regularly mailed to physicians in this vicinity, has been held in $1,500 bail, in the Essex Market Police Court, charged with having performed an illegal operation on Agnes Berthold, aged twenty nine, of 95 Seventh Street.

An Illinois News Item.—Our school is still closed on account of the teacher's confinement. Mumps.—*Schiller Sun.*

The Association of Military Surgeons meets in Washington on May 1st. Six army surgeons will be sent as delegates to the meeting.

Favoring the Bill for a National Bureau of Health.—The New York Chamber of Commerce Committee on Quarantine, appointed last year to co-operate with the Health Officer in protecting this port against cholera, have reported a resolution, which was adopted, favoring the bill in Congress to establish a Bureau of Public Health in the Interior Department.

The Middleton Goldsmith Leeture of the New York Pathological Society, for 1894, will be delivered at the New York Academy of Medicine on Saturday, April 28th, at 8.30 P.M., by Professor William H. Welch, of Johns Hopkins University. Subject: "Mixed and Secondary Infections."

The Merritt H. Cash Prize.—The Medical Society of the State of New York offers a prize of $100, payable from the Merritt H. Cash Prize Fund, for the best original essay on any medical or surgical subject. The conditions are: That the competitor shall reside in the State of New York, and shall be a member of a county medical society; that the essay shall be either printed or type-written; that each essay shall be designated by a motto on the title-page, and accompanied by a sealed paper bearing the same motto and enclosing the name of its author, in order that the name of the successful author alone may be ascertained; and that all essays shall be sent to the Chairman of the Committee on Prize Essays, prior to January 1st next. The Committee on Prize Essays are: Dr. Franklin Townsend, Jr., 2 Park Place, Albany; Dr. A. Walter Suiter, Herkimer; Dr. Charles Stover, Amsterdam.

The Late Dr. J. H. Sinnett.—At a meeting of the medical staff of the Demilt Dispensary, held March 22d, the following preamble and resolutions were adopted:

Whereas, We have learned with the deepest regret of the untimely death of Dr. John H. Sinnett, incurred in the discharge of duty,

Resolved, That the Medical Staff of the Demilt Dispensary desire to place on record their appreciation of the high standing of their late colleague, their feeling of loss sustained by the profession in this early death, and their heartfelt sympathy with his bereaved wife and family;

Resolved, That a copy of this resolution be forwarded to the New York Medical Record, the *New York Medical Journal,* and to his family.

Henry D. Chapin, M.D.,
John Dorning, M.D.,
Joseph E. Winters, M.D., *Committee.*

Examinations for the United States Army Medical Corps.—In view of the possibility of the reduction of the Medical Corps from one hundred and twenty-five to ninety Assistant Surgeons, by action of Congress at its present session, and to save possible loss of time and expense to candidates if such action be taken, the examinations appointed for April, 1894, will, by order of the Secretary of War, not be held until further notice. It is probable that if the Corps should not be reduced, the Examining Board will be convened in the fall of 1894. Of this, notice as early as possible will be given.

Five Hundred and Sixty five Quarts of Beer for each man, woman, and child in the city is the amount annually consumed in Munich.

The Pope Tries Hydrotherapy.—Father Kneipp, the German priest and preacher of hydrotherapy, was consulted, on the occasion of a recent visit to Rome, by Leo XIII. for the relief of certain ailments, due to advanced age, from which his Holiness is suffering. The Pope was advised to apply cold compresses to his knees and the back of his neck, and did so with rather disastrous results. He caught quite a severe cold, and both knees became so swollen that he was forced to call upon his own physician to combat the consequences of the experiment. Monsignor Kneipp is not thought so much of in the Vatican as he was.

Medical College Commencements.—The Medical Department of the University of Wooster, Cleveland, O., held its Commencement exercises March 21st, and conferred the degree of M.D. on ten graduates.

The University Medical College of Kansas City held its Commencement March 20th. There were nineteen graduates.

The Cleveland University held its Commencement March 20th, and conferred the degree of M.D. on thirty graduates. Four graduates received the degree of D.D.S.

The Kansas City Medical College, at its twenty-fifth annual Commencement, March 22d, awarded diplomas to thirty two graduates.

The Barnes Medical College of St. Louis, Mo., held its Commencement March 20th, and forty-two graduates received the degree of M.D.

The Long Island College Hospital held its thirty-fifth annual Commencement March 21st. There were fifty-four graduates.

The Wisconsin College of Physicians and Surgeons at Milwaukee graduated two students March 26th.

Typhoid in Montclair, N. J.—There is an epidemic of typhoid fever in Montclair, N. J., traceable to contaminated milk supplied by a particular dealer to his customers. The cows of the dairy drank from an infected spring, and the milk-cans were washed in the same.

Reviews and Notices.

The After treatment of Cases of Abdominal Section. By Christopher Martin, M.B. (Edin.), F. R. C S. (Eng.), surgeon to the Birmingham and Midland Hospital for Women. London: Simpkin, Marshall, Hamilton, Kent Co. 1894.

This is an excellent little work, abounding in practical minutiæ as to the after treatment of cases of abdominal sections, and is the outcome of an experience with a thousand cases. The author having been an associate with Lawson Tait, believes in the purgative plan for preventing peritonitis, and virtually says if you can get a passage from the bowels you can save your patient. His descriptions of the technique of dressing, management of post operative hemorrhage, and other complications, are admirably clear and thoroughly orthodox. For the man who does abdominal surgery it is almost indispensable.

Notes on Nursing in Eye Diseases. By C. S. Jeaffreson, M.D., F.R.C.S. (Eng.), etc. Bristol: John Wright & Co. 1894.

This small volume is a handbook of eye nursing based upon the every-day experience in the Newcastle Infirmary, and contains descriptions and illustrations of eye bandages, eye pads, drop bottles, the management of the operating theatre, the selection and care of instruments, and many other matters necessary for junior practitioners and nurses who give their attention to eye diseases.

Congenital Affections of the Heart. By George Carpenter, M.D. (Lond.) London: John Bale & Sons. 1894.

The author gives us a very condensed and systematized description of the pathological conditions and associated clinical signs of the more important cardiac malformations, which will be duly appreciated by the advanced student and practitioner.

Report of the Society of the Lying-in Hospital of the City of New York. 1893.

In 1890 the Midwifery Dispensary began its work of providing medical men and students of medicine with practical instruction in obstetrics, by making use of the large amount of material supplied from the poor of New York, who had previously depended upon the services of midwives. In 1892 they were amalgamated with the Society of the Lying-in Hospital of the City of New York, thereby increasing their income and making it possible for them to enlarge the field of their work.

Each year they have published a report, the last of which has just come to hand. The report includes 186 pages of printed matter, including numerous temperature charts and cuts illustrating the text. It covers a period of fifteen months, during which time they cared for 2,583 women, mostly Russians of the very poorest class. The report is to be commended as being a new departure in hospital reports. It presents not only the statistics for the past fifteen months, but also several original articles based upon the work of the hospital.

The leading article is a report of the cases of fever occurring in the service of the hospital during a period of three years.

In 3,737 puerperal cases, they find 591 cases of fever, including fever from all causes. It is to be noted that during this period many of the cases were taken as postpartum cases from midwives.

In a series of 2,283 cases, all of which were confined by the hospital, the percentage of fever was 12.7 per cent., of which 3.82 per cent. was due to septic infection. The percentage of death in all fever cases was 0.2 per cent.

The second article is a modification of Crede's method of expressing the placenta, by calling attention to the angle existing between the uterine canal and the vagina.

There follows a report of three successful cases of symphyseotomy, and a case of Cæsarean section also successful.

The reports of special departments, such as the orthopedic surgeon, and a very scholarly article on the development of the alimentary canal by the embryologist, close the report of this institution.

A Manual of General Histology. By William S. Gottheil, M.D., Professor of Pathology, American Veterinary College, New York, etc. Pp. 148. New York: Sabiston, Murray & Co. 1894.

In this manual, which is freely illustrated with remarkably good woodcuts for a volume of its size, the author lays down the general principles of histology in a very plain and simple manner. It is essentially a primer upon the subject from which mere theories and mooted points are excluded, and the explanations of the structure of the body are reduced to their simplest possible terms. It contains no directions whatever for the preparation of specimens, etc., and for this omission it is to be criticised. It will answer as preliminary reading for laboratory work, but cannot serve as a satisfactory guide for the student in his actual work of examining normal tissues.

The Microscope and Microscopical Methods. By Simon Henry Gage, Associate Professor of Anatomy, Histology, and Embryology in Cornell University. Fifth edition. Pp. 165. Ithaca: Comstock Publishing Co. 1894.

This new edition of Professor Gage's work on the microscope remains in general plan like that of former editions, that is, definitions and discussions are followed by laboratory experiments in which the student makes the demonstrations for himself. It is printed only on the left-hand page, thus leaving the right blank for notes. The figures have been increased from about fifty to one hundred and three, and have been distributed in the text in stead of being collected into plates. In matter, the book has been increased from 96 to 165 pages. This increase is due in part to the elaboration of the old text, and in part to a wholly new chapter "On Photo Micrography, and on Photographing Natural History Specimens in a Horizontal Position with a Vertical Camera."

The purpose of the book is thus briefly given by the author in the preface: "It is hoped that the book as it now appears may, while remaining strictly elementary, still more fully meet the needs of those who wish to use the microscope for serious study and investigation. The aim has been to produce a book for beginners in microscopy, such as the author himself felt sorely the need of when he began the study."

The present volume, Part I., treats especially of the microscope and histology. It will be of great service to the beginner in laboratory work, and is especially worthy of commendation for its accuracy and inculcation of true scientific methods in research.

A Manual of Minor Surgery and Bandaging. By Christopher Heath, M.D., Surgeon to University College Hospital, London, etc. Tenth edition. Pp. 389. Philadelphia: P. Blakiston, Son & Co. 1894.

Previous editions of this manual have been favorably noticed in these columns. The present embodies the results of the latest knowledge regarding antisepsis, and is a useful guide for house-surgeons and junior practitioners. Its contents cover every possible surgical emergency.

The Discovery of Modern Anæsthesia. By Whom was it made? A Brief Statement of Facts. By Laird W. Nevins, M.D., New York. Pp. 111.

The author has collected in this volume all the reliable historical data concerning this much discussed question. Nothing new is mentioned, as the ground has been so thoroughly covered in the discussions of the last ten years. Dr. Nevins gives with considerable detail the life stories of Long, Wells, Riggs, Morton, Jackson, and

Simpson, all of whom contributed to the discovery of modern anæsthetics. It is to be regretted that a narrative of this historical value should be marred by the thinly disguised attempt of the author at self-advertising.

Clinical Lectures on Pediatrics Delivered in the Vanderbilt Clinic during the Session of 1892–93. By A. Jacobi, M.D. Stenographic Reports. New York: Bailey & Fairchild. 1893.

This little book comprises about 195 pages. It is filled with practical points in the treatment of the most common diseases of children, as seen in a large dispensary and general practice. Dr. Jacobi has been too long before the profession to need introduction as a master of pediatrics, for this little volume clearly indicates that the latest and most modern theories have not been disregarded, and due weight and consideration given to all details of the present methods aimed at making the proper diagnosis in a given case. Pathology, bacteriology, and dietetics, even gymnastics, are mentioned in the brilliant article on Pulmonary Tuberculosis on pages 189–91.

Lectures on Auto-intoxication in Disease; or, Self-poisoning of the Individual. By Charles Bouchard, Professor of Pathology and Therapeutics; Member of the Academy of Medicine, and Physician to the Hospitals, Paris. Translated with a Preface by Thomas Oliver, M.A., M.D., F.R.C.P. Philadelphia: The F. A. Davis Company. London: F. J. Rebman. 1894.

This volume embraces a series of translations of thirty-two lectures. These lectures may therefore be regarded as an inquiry into the operation of poisons introduced from without or generated within the body of man, and the part they play in health and disease. No subject demands more serious study. Death frequently carries off in a few hours or days individuals who are in the prime of life and in apparent good health, and at whose post-mortem the most careful examination fails to reveal alterations of structure such as can explain the fatal stroke.

Especially interesting are the lectures on antisepsis of the internal medium relating to typhoid fever. The clear style is one of the numerous advantages offered in reading this volume, and it will repay all desiring modern views concerning medicine of to-day to study it carefully.

The Conduct of Ordinary Labor through External Examinations Solely.—Drs. Leopold and Spörlin make a warm plea for limiting examinations made in the course of ordinary labor to the external parts, and adduce the advantages of such a course. Infection is thereby avoided: the natural sense of modesty of the parturient is not offended; and careless rupture of the membranes is avoided. Skill in external examination is acquired with reasonable readiness. In the large majority of cases such examination alone is sufficient for the recognition of the position and presentation of the fœtus, and for the study of the course of an ordinary labor. As there can be no objection to its frequent exercise, abnormalities of parturition may the more readily be detected early, and means of correction promptly employed. Experience soon teaches the difference in the position of the fœtus assumed in case of pelvic contraction on the part of the mother. The position and presentation having been recognized by external examination, internal examination for the determination of possible pathologic conditions of the birth canal need be but brief, and can be conducted with great care. For the attainment of this desirable result it is essential that the obstetric pupil familiarize himself thoroughly with the conditions of normal labor as determined by physical external examination, as well as with the physiology of normal labor. Obstetric operations are principally to be taught upon the phantom.—*Medical News.*

Society Reports.

ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

Held in Rome, Italy, March 29, 30, and 31, and April 1, 2, 3, 4, and 5, 1894.

SECTION ON PRACTICAL MEDICINE.

Double Abdominal Aspiration.—Dr. Giuseppe Amalfi, of Naples, read a paper on this subject. The apparatus employed consists of, 1, an aspirator similar to that of Dieulafoy: 2, a Y-tube, each branch of which is provided with a stop cock opening or closing communication with the main tube; 3, an ordinary œsophageal tube; 4, an elastic tube with walls of the same thickness as the preceding, but double the length; 5, a piece of perforated vulcanite; 6, an ordinary rectal cannula. The main trunk of the Y-tube is attached to the aspirator, one of its arms being connected with the open end of the œsophageal sound, the other with one of the extremities of the elastic tube. The rectal cannula is fastened to the other end of this elastic tube by means of the piece of vulcanite. The apparatus is employed in the following manner: The œsophageal sound is passed into the stomach, and the rectal cannula into the lower bowel; both stop cocks are then opened and the aspirator is put in action. If it be desired to act solely upon the upper or the lower end of the digestive tract, one of the stop-cocks is closed. By a reversed action of the aspirator an injection of gas into either the stomach or the rectum may be effected. The apparatus renders great service in the treatment of the various forms of colic.

Treatment of Small-pox.—Dr. Oreste Gamba, of Rome, has found sulphide of calcium to be the most efficacious remedy in the treatment of small pox. As the complications of the disease are seen most frequently in the respiratory organs, he insisted upon the necessity of a well-aired and disinfected sick-room. He urged the utility of revaccination, as repeated observations had shown that the immunity against variola resulting from vaccination disappeared after a certain time. Mortality statistics demonstrate that the prognosis is bad in patients from one to fifteen years of age, is fairly good between the ages of sixteen and thirty, and become serious again in patients from thirty-one to sixty years of age.

Salipyrin.—Dr. Artur Henning, of Königsberg, read a paper on this drug, which he believed to be the best antirheumatic and antineuralgic yet known, and also a most excellent antipyretic, especially in pediatric practice. In cases of rheumatism, when given in the early stages, it is most efficacious in relieving the pain and reducing the swelling of the affected parts. In simple colds and acute coryza it exerts a very favorable influence upon the headache and general malaise. Its action in influenza must be regarded as almost specific. In cases of uterine hemorrhage, not due to the presence of tumors, or occurring in childbirth, salipyrin is much more efficacious than any other known remedy.

The drug is absolutely safe, and gives rise to no unpleasant after-effects. It is best given in the afternoon, in rather large doses, repeated at short intervals. The total daily dose ranges from 7½ grains to 2 drachms, according to the age of the patient and the disease. The remedy has no cumulative effect, nor do those taking it acquire a habit.

Muscular Contracture in Myopathies.—Dr. R. Lépine, of Lyons, said that the muscular contractures noted by Landouzy and others in cases of myopathic atrophy, may exist under various forms in the atrophic or pseudo-hypertrophic myopathies of the lower extremities, and may be one of the chief causes of the interference with the power of locomotion.

Direct Transfusion of Blood from the Dog to Man.—Dr. Nicola de Domenicis, of Naples, presented a communication on this subject, the conclusions of which

were that direct arterial transfusion of the blood of a dog into the human subject was not only well tolerated but was also very beneficial. He thought that this measure ought to be recognized as a useful therapeutic agent.

Morphological Examination of the Individual.—Dr. Achille de Giovanni, of Padua, read a paper with this title, in which he said that the scope of the examination was the determination of the individuality, in order to be able to recognize, through the individual differences, the cause of the clinical differences observed in the same disease. The examination consists in the mensuration of the body and of all its parts, the determination of the proportional development of the viscera, and of the individual's corporal and mental powers.

A Classification of the Causes of Diseases, for Practical Use in the Examination of Patients.—Dr. T. Churton, of Leeds, England, presented the following scheme, which he had drawn up for the guidance of hospital internes:

Investigation of Causation.—1. Find the limit of working power of the muscles, cord, and brain of the person in health, thus: *a*, greatest weight he could lift; *b*, greatest distance walked or run with ease in a day, in an hour, in a minute; *c*, greatest number of hours of daily work; α, storing impressions, visual, auditory, etc.; β, thought or invention; γ, output, muscular work, speaking, writing, governing; *d*, control of sensori-motor mechanism; time-limit of attention to one subject, curiosity, interest in society, politics, etc.; altruism (regard of other persons' interests, conditions, and sentiments).

2. Find date of first impressions of loss of energy or faculty of any kind—receptive, retentive (memory), active, inventive, social; also the date of first symptoms of disorder in subservient organs (digestive, etc.).

3. Find the causes which were, at the dates given, operating to produce these changes.

Causes of Disease.—1. Original constitution of organs, shown by: *a*, history of parents, grandparents, brothers, sisters, uncles, aunts—their ages, energies, diseases (especially nervous diseases, syphilis, gout, rheumatism, tubercle, hemorrhages, kidney and skin diseases), modes of death; *b*, diseases of members of the family whom the patient most resembles.

2. Acquired changes in constitutions of adults may be shown by the children (if any) of the patient.

3. Conditions, remote or recent, of (*a*) quantity or (*b*) quality of the patient's "necessaries of life"—*a*, food: animal, vegetable, mineral; drink: oxygen, supply by day and by night; *b*, clothing: by day and by night (including bedroom); house: drainage, water-supply, dryness, etc.; *c*, work, rest, sleep.

4. Adverse influences: *a*, animal—struggle for existence and luxury, emotions, anxiety, disappointment, shock; *b*, parasites—worms, insects, microbes introduced through food or air, or through skin, uncleansed or abraded; gonorrhœa, syphilis, ague, rheumatism, tuberculosis, fevers; *c*, plants—ipecac, rhus toxicodendron, etc. (which produce unusual effects in certain persons); *d*, chemical substances derived from (α), animals—sewer emanations, odors (*e.g.*, of rabbits causing asthma); (β), plants—tea, tobacco, opium, etc.; (γ), minerals—arsenic, lead, sulphur, etc., dust (meteoric, telluric), adulterations of carelessness (as of chloride of tin in some sugar) or of design; (δ), artificial—alcohol, fusel oil, antipyrin, chloral, paraffin, and other common articles of commerce; *d*, forces in excess or defect—(α), heat or cold, dry or wet; (β), electricity (? weather changes and climate); (γ), light; (δ), mechanical—injuries, external or internal, resulting from diseases of other parts (atrophy, hypertrophy, inflammation, new-growths, foreign bodies, functional disorders), compression (fracture), strain, rupture, stretching.

Studies and Observations on Protoplasm.—Dr. Angelo Ceconi, of Padua, read a paper recounting some researches made by him upon the bone marrow and subcutaneous connective tissue, the results of which led him to accept wholly the granular theory of protoplasm advanced by Altmann. The bioblasts of this author are really living forms possessing the activities of the cell, such as the absorption of fats and of albuminoids, secretion, etc. Pathology must henceforth occupy itself with the biomorphic granules of protoplasm, which must be regarded as the fundamental unit of living matter.

A Modified Method of Physical Diagnosis.—Dr. Bendersky, of Kieff, described a method of physical examination of the internal organs, especially of the stomach and intestine, which he regarded as novel. It consisted in auscultation with a modified otoscope or flexible stethoscope, while at the same time percussion was made. The limits of the abdominal organs can thus be mapped out more accurately than by percussion alone. A demonstration of the method, which was simply the well-known auscultatory-percussion, was made in the meeting.

Toxalbumins of Cancer.—Dr. Boinet, of Marseilles, presented a communication recounting the bacteriochemical experiments which he had made in various forms of cancer (melanosis, lymphadenoma, epithelioma, and mammary carcinoma). He had made a number of inoculations in rats, guinea-pigs, and rabbits with cultures, pieces of malignant tumors, and cancer juice. The author dwelt especially upon his chemical experiments, describing his method of extraction of the toxalbumins and ptomaïnes, their chemical reactions, and their physical characteristics. The phlogogenic action of these toxalbumins was slight; there were noticed tremors, accelerated respiration, pulmonary, renal, cerebral, and bulbar congestion; when given in smaller doses a cachetic emaciation was induced. A sort of vaccinal attenuation was noted in some animals which had been previously inoculated with fragments of carcinomatous tissue, cancer juice, or the toxalbumins of lymphosarcoma or cancer. Such animals were able to resist doses of the toxines twice as strong as those which killed in a few hours non-protected animals.

Motor Troubles in Malaria.—Dr. Boinet, of Marseilles, said that, while resident in Tonkin, and also in the hospitals of Marseilles, he had observed a great variety of motor troubles of malarial origin, which he grouped under the following heads:

I. *Paralysis.*—1. Transitory. These forms were associated with the febrile paroxysm, passing away when that subsided, or at most persisting only a few days; they yielded to the action of quinine. They usually have the characteristics of cortical paralysis. The aphasic variety may appear in simple malarial fever, but is more common in the pernicious forms; it rarely occurs alone, but is more commonly associated with hemiplegia, monoplegia, or paraplegia; hemiplegia occurs with aphasia in about two-thirds of the cases. Facial paralysis is rather unusual. 2. Monoplegia is sometimes confined to very limited groups of muscles, being restricted in one case cited to the district supplied by the ulnar nerve. These paralyses are usually limited, not progressive, transitory and curable, varying frequently, however, in seat and in intensity, possessing, in a word, all the characteristics of cortical paralysis. Nevertheless, they may in certain cases be persistent, generalized, and attacking successively the four extremities, being then of medullary origin. Maillot has found, indeed, marked congestion, softening and hemorrhagic foci in the medulla in these forms. 3. Malarial paraplegia may be accompanied by atrophy and present the characteristics of beriberi; it is not gradually progressive, like dysenteric paralysis, but is often sudden and complete in its onset, being most pronounced at the periphery; as a rule, the bladder and rectum are not involved. There are neuralgic pains, sometimes fulgurant, at the outset, and cutaneous hyperæsthesia is often present, though anæsthesia may exist from the start. Muscular hyperæsthesia, with atrophy, was present in one case reported. Sometimes the paraplegia is persistent; this occurs in the pernicious forms of malarial disease, or may be seen in intermittent fever following a

succession of transitory attacks of paraplegia. 4. Muscular atrophies sometimes appear suddenly, and sometimes follow contractures. These atrophies of medullary origin exist *en masse*, involving at times an entire segment of a limb. The atrophy may also be dependent upon peripheral neuritis (sciatic or ulnar). Certain forms of pseudo-tabes are likewise associated with these peripheral neurites.

II. *Convulsive Troubles.* — 1. Tremor: Rhythmic movements may be induced only by attempts at voluntary motion, or they may persist during periods of repose. They may be limited to the upper extremities. 2. Choreic form: This is often a toxic hysteria of malarial origin. There may also be tremors resembling in type those occurring in paralysis agitans or in pseudo-sclérose en plaques; the author had observed one case of pseudo-tabes of malarial origin. 3. Athetosic movements of the right hand: one such case was seen after an attack of pernicious remittent fever. 4. Spasmodic contractions of the left upper extremity. 5. Intermittent tetanus, tetany. 6. Convulsions limited to the thoracic extremities. 7. In one case there was contraction of the upper extremities.

Prognosis.—The cortical paralyses, often hysterical, are the most transitory; the myelopathic paraplegias are the most grave, since well-defined lesions of the medulla have been found here. In cases of multiple neuritis the prognosis is more favorable, but is apt to be serious when atrophy occurs rapidly. Finally the prognosis is good in the case of those motor troubles which are often associated with toxic hysteria arising under the influence of malarial poison.

Caffeine in Malarial Fevers.—Dr. Federico Biscini, of Montecompatri, Italy, said that physicians in ancient and modern times had used coffee with good results in the treatment of malarial fevers. Black coffee, with the addition of lemon juice, is used in intermittent fevers in places as remote as Morocco and Mississippi, and many authors regard it as one of the most efficacious remedies in these affections. The French army surgeons in Algiers resort to it whenever their supply of quinine gives out. Douzin (Bouchardat's *Annales de Thérapeutique*) lauds a decoction of unroasted coffee in periodic fevers. We find it recommended by Murray and also by Paldames, who prefers the powder of raw coffee, and by Weber, who uses the alcoholic tincture. Delioux gives a decoction of coffee in doses of one to two ounces every hour before the paroxysm, and looks upon it as one of our most powerful febrifuges. Many others also have spoken of it in the highest terms. To Grindel, however, is due the credit of a thorough experimental study of this remedy, and he regards it as one of the best succedanea of quinine. He made these studies in Dorpat, Russia, and among a large number of cases of intermittent fever found very few which resisted the action of coffee. Others have succeeded in curing by this remedy many cases which had proved rebellious to quinine. Contani, Niemeyer, and others speak in the same terms of the remedy. Since so many clinicians have obtained excellent results with coffee, why should we not make experiments with caffeine? The author desired to recommend the experiments with caffeine and its salts, including the arseniate, to the members of the Congress, himself not having had enough cases to enable him to come to a definite conclusion as to their value, his practice being in a district where but little malarial fever was encountered.

Cardiometria.—Dr. Espina y Capo, of Madrid, presented a communication on the measurements of the heart, in which he presented the following conclusions: 1, In order to trace the limits of the cardiac area one should start from previously known data; 2, the author took, by preference, the lines of Traube and of Friedreich; 3, in order to map out distinctly the borders of the heart we must employ both strong and light percussion; 4, in pathological cases we should always previously mark the normal area of the heart for the purposes of comparison.

The Determination of the Size of the Heart in the Living Subject.—Dr. W. Ebstein, of Göttingen, has employed for the past twenty-five years the method of palpatory percussion to determine the form and size of the heart, and to map it out on the anterior thoracic wall; that is, he endeavors, by means of the feeling of increased resistance which is experienced over the heart, to determine its position and size. The author gave a practical demonstration of this method, which he believed to be the most exact as well as the most easily executed, and one which served the purposes of the scientific diagnostician and of the practising physician in equal measure.

Electricity in the Study of Cardiac Arythmia.—Dr Luigi Bordoni, of Sienna, said that certain forms of cardiac irregularity, especially those seen in bigeminism, disappear upon electrical stimulation (continuous current) applied to the neck. It is admissible, therefore, to suppose that moderate excitation of the vagus may be useful for the relief of some of these forms, while, on the contrary, strong stimulation (as already shown by various writers) may favor their occurrence. From this the author concluded that the mode of reaction of the various forms of cardiac arythmia to electrical applications might be useful clinically as a means of distinguishing the nervous varieties from those of mechanical or myocardic origin.

Cardiac Arythmia in Infectious Diseases and Sclerosis of the Heart.—Dr. Bordoni also read a paper on this subject, the conclusions of which were that the analysis of various forms of arythmia in these affections was useful in the discussion of the functional nature of the cardiac ganglia, and favored the view that certain motor centres were present in the heart itself.

Periodic Cardiac Rhythm.—The same author then related two cases in which a long pause occurred regularly in the procession of heart-beats. Both patients were subject to epileptiform attacks, and the speaker referred the phenomenon to a supra-excitation of the vagus.

Nature of the Cardiac Ganglia.—In a fourth paper Dr. Bordoni spoke of a number of clinical experiments he had made, which would seem to show that the cardiac ganglia were not exclusively sensitive. They are connected with the motor centres, and if they are not strictly necessary to the production of the rhythmical contractions of the heart, they are at least auxiliary to the regularity of the cardiac rhythm and aid in a special manner the ventricular contractions.

Dissecting Aneurism of the Aorta.—Dr. Cerchez, of Berlad, Roumania, reported a case of dissecting aneurism of the aorta which had destroyed almost the entire anterior wall of the thorax, and showed a cast and photographs of the lesion. He said the case was interesting because of—1, its volume and the destruction which it had caused; 2, the perforation of the chest wall during life, the patient having survived this destruction for a long period notwithstanding repeated and copious hemorrhages; 3, the mode of death, which resulted from compression of the larger bronchi and trachea, and from syncope induced by the hemorrhages.

The Hepatic Pulse.—Dr. Giuseppe Dagnini, of Bologna, said that he had observed, in a patient suffering from mitral stenosis and insufficiency, a presystolic hepatic pulsation so strong as to simulate the pulsation found in tricuspid insufficiency. The curve of this pulsation corresponded in form to that resulting from the changes in pressure in the cardiac ventricles. At the end of the descending line of the curve there was a slight undulation corresponding to the beginning of the ventricular diastole. During the presystolic period, in the time of the expansion of the liver, there was noted a depression of the thoracic wall over the level of the right auricle, a strong pulsation in the jugular, and, after a brief interval, a pulsation in the crural vein. These phenomena indicated a considerable dilatation and hypertrophy of the right heart, together with an insufficiency of the orifice of the vena cava, and an obstacle to the emptying of the corresponding ventricle. He had seen other cases of

presystolic hepatic pulse, but none so strongly marked as the one reported.

A Ptomaïne Obtained from Hydatid Cysts of the Liver.—Dr. Boinet, of Marseilles, had extracted a ptomaïne from hydatid cysts of the liver which was obtained in the form of long, silky, prismatic crystals, arranged in the shape of fern leaves; the crystals were translucent and soluble in water. Three milligrammes of this ptomaïne injected under the skin of a mouse caused death in five minutes: five centigrammes injected into the veins of a rabbit gave rise to symptoms of hydatid intoxication, convulsions, first accelerated then retarded respiration, rapid action of the heart, dilatation of the pupils, collapse, and a reduction of temperature to about 80° F. Death was preceded by a few convulsive attacks. A patient with hydatids of the liver succumbed with symptoms of rapid respiration and convulsions, followed by paresis of the lower extremities very similar to those observed in the animals experimented upon. This toxine is found more abundantly in cases in which puncture and electrolysis have modified the vitality of the hydatids, transforming the clear fluid into a yellowish, turbid, sirupy liquid, rich in albuminoid matters. It resembles the mytilotoxine of mussels, and results probably from the reduplication of the albuminoid matters. In conclusion, the author said that this ptomaïne seemed to exercise a toxic action upon the still intact hydatid vesicles, causing their aseptic necrosis and death.

Cirrhosis of the Liver.—Dr. Alessandro Cantieri, of Sienna, read a paper entitled "Clinical and Anatomico-pathological Studies on Hepatic Cirrhosis." This condition, he said, consists solely in proliferation, hyperplasia, and hypertrophy of the perivenous connective tissue, having its origin most frequently in an endophlebitis, which extends by continuity to the outer surface of the vessels; the irritation and chronic inflammation surrounding the vena porta extends throughout the portal perivascular connective tissue (exophlebitis, periphlebitis).

With this chronic connective-tissue inflammation, which often spreads to the suprahepatic veins, there may also arise, contemporaneously or later, a phlebitis of these vessels, which in its turn gives rise to a connective-tissue hyperplasia, the condition being then a bivenous hepatic cirrhosis. With whichever form we have to deal the effects are the same—compression of the acini and lobules, increase of the connective tissue and of the delicate intercellular trabeculæ, leading to destruction of the hepatic cells, shrinking of the organ, and almost total abolition of its functions.

The irritation and chronic inflammation of the connective tissue may have another origin. Thus it may arise from an endo-angiocholitis passing through the walls of the vessels and becoming an exoangiocholitis, and then, following the pericanicular connective tissue, the hyperplasia may extend to the entire organ, causing a hypertrophic biliary cirrhosis. This increase in size of the liver is due to the great increase in the connective tissue, to the dilatation and new formation of the biliary canaliculi, and to the fact that the hepatic cells remain intact and increase in size, or, as some maintain, even become more numerous. It is only the peripheral cells of the lobule which are compressed or at times destroyed.

The new-formed interstitial connective tissue is the only constant cause of hepatic cirrhosis. The anatomical distribution of this tissue and its destructive action upon the hepatic cells explains sufficiently the anatomical alterations of the organ, and at the same time the clinical and physiological changes, the increase or decrease in weight and volume.

The distinction which has been made between the several varieties of cirrhosis seemed to the speaker to be superfluous, for the disease always consists in a connective-tissue hyperplasia caused by an infection or intoxication. The most common causes are the abuse of wine or spirituous liquors, or the habitual ingestion of too highly seasoned food; the closure of the common duct by a calculus: the penetration of intestinal micro-organisms into the organ by means of the blood of the portal vein or through the stagnant and altered bile filling the canaliculi; or poisoning by the biochemical microbic products present in quantity in the intestines or blood. In malarial cirrhosis we find in the liver a great number of pigment granules, the remains of the red blood-globules destroyed by the plasmodium, and also other minute corpuscles which are believed to be the scoriæ of the plasmodia. All these corpuscles collected in the liver, which can no longer exercise its epurating functions, remain there as inert bodies, but they inflame the walls of the portal vein which brings them there, and also perhaps the bile-ducts, a result of which is that malarial cirrhosis partakes of the clearly marked characters of neither venous nor biliary cirrhosis.

The other forms, whether with fatty or amyloid degeneration, tuberculosis or cancer, are all varieties of cirrhosis, either venous or biliary or mixed; the other diseases or forms of degeneration are merely accidental complications which cannot of right give their name to the hepatic disease.

In concluding the author said that his experiments were still in progress, and it might be that the results of them would lead him eventually to modify to some extent the views here expressed.

Icteric Pruritus.—Dr. Bouchard, of Paris, read a paper with this title, in which he said that the cutaneous pruritus, so common in jaundice from retention, may also appear and persist a long time before the icterus is evident. This precocious pruritus is observed especially in those cases in which the obstruction to the flow of bile is caused by a neoplasm situated somewhere along the course of the biliary passages.

The Treatment of Jaundice.—Dr. M. Alivia, of Viterbo, read a paper on this subject, of which the following were the conclusions: 1. Long-continued biliary stasis, compromising the secreting cells of the parenchyma of the liver and producing a certain anæmia of the organ, markedly reduces, and sometimes suppresses, the secretion of the biliary acids. The gravity of the phenomena described under the name of biliary intoxication, does not therefore depend upon the action of these acids. 2. The scarcity or absence of bile in the intestinal canal modifies very seriously the chemical processes there taking place. 3. One of the most common of the gastric changes in icterus is the suppression of hydrochloric-acid secretion. 4. There is little or no loss of carbonate of sodium in these cases. 5. The reaction of the contents of the stomach is usually alkaline, less often neutral or faintly acid. 6. The physiological activity of the bile and of the pancreatic juice in the intestine is retarded. 7. The chlorides in the urine are increased, the reaction of the fluid is often alkaline, there is a diminution of urea with an abundance of products of the aromatic series. 8. The more marked are these characters so much the more grave are the disease and its clinical manifestations. 9. Alkaline treatment does not modify these conditions. The effect of the acid treatment is, however, to diminish the chlorides, to restore the normal acidity of the urinary reaction, to increase the excretion of urea, and to reduce that of the aromatic products; and at the same time there is a progressive increase in the weight of the body.

The Causal Treatment of Tuberculosis.—Dr. E. Klebs, of Karlsruhe, read a paper with this title. In order to obtain curative substances from the culture fluids of tubercle bacilli, those parts which are soluble in alcohol must be removed. The matters left after treatment with alcohol belong to the class of albuminoids and peptones. Among these we find toxalbumins which are precipitated by a sodium bismuth-iodide solution and may in this way be removed. These substances only are useful in a diagnostic sense, for which purpose a solution containing only a third part of the toxalbumins is employed. The albuminoses which are not precipitated by the sodium bismuth-iodide solution are called collectively "tuberculocidin," since they are directly fatal to the tubercle

bacilli. The solution of these albuminoses remaining after the removal of the bismuth and iodine salts is known as "antiphthisin."

Through the action of this antiphthisin a complete cure of tuberculosis may be obtained in the lower animals and in man. This cure takes place in consequence of the destruction of the tubercle bacilli and of the resolution of the tubercular tissues. It is accomplished without any fever or inflammatory reaction. An elevation of temperature occurs only when the destruction of the tubercle bacilli has been effected too rapidly, and therefore in very severe cases the remedy must be administered in gradually increasing doses.

During the process of destruction of the bacilli and resolution of the tuberculous tissues, there occurs a slight leucocytosis and an exudation of fluid containing globulin from the blood-vessels. The extravasated leucocytes are probably the carriers of the therapeutic agent, and also contain the material necessary for the conversion of the tubercle-cells, which are poor in chromatin, into normal cells. The exudate containing globulin furnishes the material for the reconstruction of the cell-body.

The antiphthisin must be administered in such a way as to bring it as close as possible to the diseased parts. When it is desired to act through the blood a rectal injection will suffice, but in other cases a local application, varying according to the seat and nature of the diseased parts, is to be preferred. In the case of pulmonary phthisis an injection into the trachea (up to the limit of 3 c c. at a dose) is to be made; in other cases, where the affected part is directly accessible, as the joints, bones, glands, or skin, an injection *in situ* is indicated. Where there is a special collection of tubercular tissue in an accessible region, as for instance, in lupus or caseous infiltration of the bones, a removal of the diseased part by surgical means is to be recommended.

The dosage of antiphthisin is estimated by T. C. units, by which term is to be understood the amount of tuberculocidin, the active substance contained in 1 c.c. of the original tubercle culture fluid. As a rule, when fever is present, we must begin with one T. C. unit and, according as the pyrexia increases or diminishes through the reaction caused by the destruction of tubercle bacilli, gradually or rapidly increase the dose up to 50 T. C. units per diem, administered partly locally and partly through the circulation, by means of rectal injections. In the first month from 100 to 200 T. C. units may be given in twenty five injections, in the second month from 300 to 400, and in the third from 500 to 1,000. In the milder cases a cure may be obtained by a total dose of about 1,000 T. C. units given in the course of three months. After this, during a second period of treatment, the maximum dose may be administered once or twice a week.

In other cases, when cavities are present in the lungs, and when there is an evident tendency to recurrence, a second course of treatment may be undertaken after an interval of at most two months. An indication of improvement is the degeneration and decrease of tubercle bacilli in the sputum, as well as a bettering of the general condition and an increase of weight.

Treatment of Tuberculosis.—Dr. Antonino Fienza, of Naples, read a paper with this title, of which the following were the main points: 1, The hemocine of the blood of the dog, administered hypodermically, in cases of pulmonary tuberculosis relieves the most troublesome symptoms, and may even cure the disease itself; 2, the injection of goat's blood also palliates the symptoms of pulmonary tuberculosis, without, however, curing the disease: 3, the injection of aristol, or of aristol and creosote in almond oil, may retard the progress of the affection, and may also cure it; 4, in tuberculosis of the bones or of the skin, aristol by injection, or in the form of ointment or powder, is often efficacious in curing the affection; 5, salol and essence of peppermint, administered internally or by inhalation, are also of practical value in the cure of pulmonary tuberculosis.

Treatment of Tubercular Peritonitis.—Dr. Carl Beck, of New York, read a paper with this title, the conclusions of which were as follows: 1, A diagnosis of tubercular peritonitis in the early stages is possible only in exceptional cases; 2, the injection of an iodoform-glycerine mixture (1 to 10) into the abdominal cavity has a specific anti tubercular action; 3, as this treatment is useful in other peritonitic troubles, it is particularly indicated in all doubtful cases; 4, the employment of iodoform in powder or solution is indicated after laparotomy whenever it is desired to limit secretion; 5, the absorption of the products of streptococci appears to be made less virulent in its results by the co absorption of iodoform. Of five cases of general peritonitis treated in this way, only one resulted fatally.

The Topical Treatment of Acute Articular Rheumatism.—Dr. Antonino Fienza, of Naples, said that acute articular rheumatism is one of the infectious diseases which yield to local treatment. The best application is an ointment containing a large proportion of salicylate of sodium and iodoform, with or without hyoscyamus. Under such treatment the disease yields in a short time, provided we can avoid, or render less intense, the consequences or the often dangerous localizations of the disease.

Treatment of Acute Rheumatism.—Dr. Domenico Franco, of Naples, read a paper, entitled "A New Contribution to the Treatment and Pathogenesis of Acute Rheumatic Affections," of which the conclusions were as follows:

1. Resting upon old time clinical empiricism as well as upon the results of the most recent investigations, we may say that the most rational treatment of acute rheumatism is the hyperexcitation of the cutaneous secretion. The means hitherto employed to this end are insufficient, hence the excuse for the author's recommendation of dry heat in the bed of the patient.

2. From the excellent results obtained by this method we may be allowed to modify the prevailing theory of the nature of acute rheumatism, which is at the onset an autoinfection, giving place later to a microbic infection.

Gonorrhœal Rheumatism.—Dr. Cerchez, of Berlad, Roumania, read a paper on this affection and its treatment, of which the following were the points touched upon: 1. The various forms of the disease. 2. The differences found in some cases between gonorrhœal rheumatism and rheumatism *a frigore*, and the resemblances which exist in other cases. 3. In none of the cases observed by the author were any cardiac symptoms noted. 4. Up to the present time no specific treatment has been found for this affection at all comparable in its efficacy to salicylate of sodium in acute articular rheumatism.

Purpura Hæmorrhagica.—Dr. Ignazio Carrieri, of Grottaglie, Italy, reported a case of purpura hæmorrhagica occurring in the course of chronic articular rheumatism, which was complicated also by a grave form of iritis. His experience in this case proved that purpura may be associated with chronic as well as acute rheumatism.

Treatment of Rheumatic Tetanus.—Dr. Enrico de Pietra-Leone, of Piazza Armerina, Sicily, reported three cases of rheumatic tetanus, two of opisthotonos and one of pleurosthotonos, in which he had obtained most happy results by means of Neapolitan ointment and alcoholic extract of nux vomica applied to the dorso-lumbar region, combined with the internal administration of the protoiodide of mercury. The latter was given when opportunity offered by the momentary cessation of trismus, but was suspended when salivation appeared.

(To be continued.)

The Island of Mauritius has been visited with an epidemic of small-pox, while cholera has appeared in vessels lying in the port.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

DARWINISM IN EXCELSIS.

London, March 29, 1894.

The Milroy lectures of the Royal College of Physicians were this year intrusted to Dr. Berry Haycraft, professor of physiology at University College, Cardiff, and he has succeeded in arresting the attention of many beyond the audience that usually attends our college lectures. It must be admitted that some of these functions are dreary enough, and it is not surprising that the faces of presidents and councillors sometimes look weary—not to say bored.

Dr. Haycraft took it for granted that all biologists accept Darwinism—a rather large assumption considering the utterances of Virchow, Agassiz, and many others. He holds that "selection" has produced the races of men, animals, and plants, and is the most powerful means of producing further changes; and so we ought to review our efforts to help humanity from this biological point of view. Education, charity, criminal legislation, marriage, etc., are all to be looked at from this standpoint. Selection, he says, "is fact, every bit of it, and no mere theoretical improved fancy." The only question is, How far may this law be applied? One wonders that thinking men had not, before Darwin and Wallace's time, "noticed the operation of this law as bearing upon racial change;" but it appears, on a careful examination of many of their works, that the law was indeed known to many, and he named Malthus and Frankland. Romanes tells us that the idea occurred to Dr. Wells in 1813, and to Mr. Patrick Matthew in 1831. If we grant the operation of natural selection as affecting race change—now we are told universally admitted among biologists—there yet remains the questions, How much race change has been due to selection? Is there also a concomitant transmission of acquired inborn characters (Lamarck's view)? Darwin thought there was, and founded on it his theory of pangenesis.

Here we may pause to remark that long before Darwin "selection" had been relied on by both breeders of animals and gardeners to produce certain variations in animals and plants. The "cow with the crumply horn" of the nursery rhyme, as well as her hornless sister, were familiar enough, as were the varieties of roses and tulips on which many had lavished fortunes. The tameness of domestic animals is considered by biologists as caused by selection, not by inheritance of the result of taming, and Dr. Haycraft remarked that this selection must be going on at the present time. This is obvious; savage dogs are continually being destroyed, and house dogs are in most cases selected from those that are docile and of good temper. One that does not possess these qualities can have no place in town or village life, and so, by continual extermination of the unfriendly, the "friend of man" has gradually been evolved, he added. It must be admitted that there are many cases about which no explanation can be given from the selective point of view, such, for instance, as the effect of climate upon the wool of sheep. In these cases, however, the information we possess is often of a slight nature, so that judgment can hardly be given at present, and all we can say is that, the closer these cases are studied, the greater is the number which suffer a ready explanation as being cases which have been brought into existence through selection. This being so, the direct evidence we possess that experimentally induced changes, such as the effects of mutilations and compressions of various parts of the body, are in no cases transmitted, while we can vary an animal or plant almost at will by selective agencies, points strongly to selection as being the prime producer of racial change, while the direct action of the environment and the transmission of its effects is of little if any account.

It has also to be admitted that changes in the blood may affect the germ-cells, as they live on that fluid, and therefore constitutional variations may be transmitted, although local changes cannot. Environment may act in two ways, argued the lecturer: it may give a preference to certain innate qualities of certain members of the race, and it can undoubtedly vary the size and general well-being of a race through the parental blood. So poisons or micro-organisms introduced into the blood may cause qualitative changes in the germ-cells which will appear in the individuals which develop from them as disease or as predisposition to disease. "This is a position which would, I believe, find acceptance with every biologist, and we shall now have to see how these views apply in the social life we see around us." The application of statements generalized chiefly from the animal world to man and his conditions of life has, of course, to be made with caution, and at most we must look upon these generalizations as giving us a clew to what may be. But the lecturer held that general truths of heredity, applicable to the whole animal and vegetable world, may also apply to the *genus homo*. If men dreamed in former times of the elimination of disease and evil dispositions and incapacity, with a view to the betterment of humanity, they had not, said Dr. Haycraft, "the slightest idea as to how that change might surely be brought about. They thought that by the transmitted effects of good hygienic conditions, education, and kindly treatment this could be effected, and in that belief, as we have already partly seen, they were profoundly mistaken;" and he concluded his first lecture as follows: "The pages of history are full of stories of vast empires which, starting full of hope and vigor, have crumbled away in time and are no more. We read of these and, maybe, often wonder at the apparent waste—whole races swept away amid a million hardships, with a bare record of a page or two. We often wonder, too, whether this must be so with us, whether, as with man, a nation has its allotted time to live. From the biological standpoint we may emphatically affirm that this is not so, and that a race may be preserved and developed without catastrophe, without the terrible suffering which we have learned to regard as inevitable; that we are as everlasting as life itself."

At the second lecture we were once again with the ubiquitous microbes and their war with phagocytes, for Professor Haycraft proceeded to consider the subject of disease in relation to selection, and a rather grim prospect he presented; for while admitting that it is conceivable that immunities may be transmitted from the parents when the blood is affected, and therefore, through it the germinal cells, he held that a better explanation of the fact is that the microbes kill the patient whose phagocytes are defeated, while those whose phagocytes are victorious recover; and thus the weaker perish, and the selective agency of the microbes improves the race.

As we may explain these cases by selection, he thinks it unnecessary to assume that the germ cells are affected. Thus the microbes of infectious diseases, including, say, measles, small-pox, chicken-pox, scarlet fever, typhus fever, and typhoid fever, living in a healthy body, in an uncomplicated case pass away and leave no trace behind except upon the quality of the phagocyte army, and the race is altered in respect to the particular microbe to which it is rendered partially immune. If, then, as he thinks, "it is extremely probable, say, in the next hundred years, we shall altogether banish this group of microbes from Europe, we must not expect to see any racial improvements—nay, rather the reverse. During an attack, for instance, of measles, although life or death may depend chiefly on the power of the phagocytes to resist and destroy the microbes, any concomitant weakness may decide the case, so that these diseases to a certain extent are race-improvers, inasmuch as they prevent a larger number of weak than of strong children from growing to maturity and contributing to the production of the next generation. There are other microbes which, in addition to the production of blood-changes, have a profound and lasting effect upon many of the tissues of the body.

Such are the microbes of leprosy." Another example mentioned is tubercle. Sufferers from phthisis are prone to other diseases, such as pulmonary and bronchial attacks, so that, over and above the vulnerability to this one form of microbe, they are to be looked upon as unsuited not only for the battle of life, but especially for parentage and for the multiplication of the conditions from which they themselves suffer. The phthisical, too, are attractive in personal appearance on account of their rich skin and hair coloring, and their frequent brightness and vivacity, and their obvious delicacy elicits a feeling of pity and wish to protect them. In consequence of this they easily marry, and they are also very fertile.

This phthisical type is very common, and it appears to be an innate variation to which our race is liable. So people with the tuberculous variation who, even under the present circumstances, manage to contribute their quota to the population, would, were the bacillus tuberculosus altogether exterminated, contribute more than their share, and the type would become more common. But this type, apart from the action of the bacillus, being a delicate and fragile one and liable to other affections, the effect of giving it any advantage in the struggle for life would imperil the well-being of the future of the race; and so, Dr. Haycraft concluded, had the Koch cure proved "as efficient as the more sanguine were led to expect, it would be terrible to contemplate the eventual suffering that would have resulted from the constantly increasing numbers of the phthisical type that would have been born with each generation. The bacillus tuberculosus is a friend of the race, for it attacks no healthy man or woman, but only the feeble." He went on to say it attacks not only the poor, ill-fed, and ill conditioned, but also those who live well. It is a disease of all, and those who live in well-ventilated rooms, and who conform to every sanitary regulation, may still belong to the type who fall a prey to it. It is certain, therefore, that, improve the external conditions of life how you will, this type will remain. It is also certain that, by giving the type a better chance than it has already, by preventing infection or by delaying the disease, it will be more and more prevalent as each generation comes to life. It comes out pretty clearly, from our short study of the infective diseases, that some of the microbes that cause these, such as the bacillus of tubercle, only feed on unhealthy human tissue, while the greater number of them kill, if anything, the weak rather than the strong. They are, on the whole, our race friends rather than our foes, and if we attempt seriously to do away with their selective influence—viz., the elimination of the weak and the preservation of the strong—we must supply this selective influence by something else, or the race will tend to deteriorate. Therefore, continued he, "*pari passu* with our endeavor to prevent these diseases must be our efforts to procure that human reason and care to avoid suffering shall all be enlisted in such selection as shall necessitate the birth of future generations from the healthiest and best. As selection is the race changer, we must replace selection by the microbe by the selection of human forethought." The case put by the lecturer is strong as far as it goes, but many will exclaim that it is very partial. Is robustness or physical strength the one good for us to seek? It is easy to see that such statements would have great weight so far as they concern the necessities of uncivilized communities depending for existence on hunting and fighting. Romans, with whom virtue meant courage in fight and in endurance, might rejoice in such a philosophy; but are we, in the nineteenth century, to place physical strength before all other qualifications? Are not the mental endowments of what these biologists call the weak types of some value? Poets and thinkers of all classes have often been feeble, sickly, diseased, yet what should we have been without them? A Napoleon may think the first duty of woman is to give birth to food for powder, and biologists may fancy that progress means the development of a race of giant athletes; but surely such views will find little echo in that profession, the nobility of which is to save the weakest and relieve the suffering.

But we must pass on. The case of the insane need not detain us. The hereditariness of the neurotic type is admitted. As to the drunkard, it seems the effects of alcohol are transmitted, and in any community where the vice is universal the lecturer thought a case for prevention was made out; but if there remained facilities for marriage the removal of alcohol would remove a selective agency, and so tend to deteriorate the race.

How, then, are we to improve the race? Dr. Haycraft says that we have absolutely no foundation for assuming that, because the average longevity has increased during the last half-century, we are more robust than we were. "The evidence is quite the other way." And he adds that "in innate qualities, whether of mind or body, we are dealing with something which suffers transmission, and if, as all admit, the general conditions of life have improved, and the sickly are kept alive as they were not formerly, it follows that these sickly ones have contributed in our century a greater proportion of their qualities to the race than in any previous century of our history. We are absolutely safe in assuming this, for up to the present time almost the only factors which have determined marriage have been mutual regard and social considerations."

People with strong strains of insanity or phthisis marry freely, and there is at present almost no strong public feeling against such a course. The fact of the matter is that, in less advanced times than the present, an abundant and ever-recruited population was almost the determining condition of a nation's existence. The depopulation produced by war and zymotic disease was so dreadful that nations with great fertility alone survived. Thus it came about that all minor differences were overlooked in the one great necessity, that of keeping up a population large enough to resist extinction or to make conquest. The problem of sickly, diseased offspring had not arisen, for all such died in infancy, and the man was most blessed who had the greatest number of children. No sin or disgrace was attached to the begetting of children destined to incapacity, was dreamed of. Now the conditions are changed, we are not liable to the black death, or a war of extermination, and this alone alters for us the problem of child production. The sickly and diseased have married when they would, "without let or hindrance, and may with certainty be assumed to have by so much the more produced a race deterioration among us."

The tendency of events is, therefore, to remove selective agencies, whereby people escape death and live in greater numbers through the child-bearing period into their forties. And as this has been going on in the past and is continuing, we cannot "shirk the fact that preventive medicine and civilization between them have already deteriorated in a marked degree the healthy vigor of our race." He holds, therefore, that if things continue in their present course it is fair to assume that "in a hundred years or so, the wretched products of our race—embodiments of every constitutional disorder, transmitted by ancestry from whose ranks the diseased have not been weeded out before the child-bearing period was over by those natural agencies hitherto free to act—will drag out their lives, martyrs to surroundings which they have tried to mould; they who, as a race, should have been moulded by their surroundings. People hardly realize that, as regards freedom from selective agents, no race of animals or men have ever been in the condition in which we find ourselves to day. The civilizations of Greece and Rome, redundant in art and philosophy, were hotbeds of disease, war, and famine, while among our ancestors there was added to these selective agencies the exposure to the rigors of a northern climate. Preventive medicine is trying a unique experiment, and the effect is already discernible —race decay. But the experiment has gone quite far enough, and it should be modified to produce a different result. Why should the microbe select? Why not public humanity and public reason, since selection there must be? This appears to me to be the only possible solution

of the difficulty, for it is not to be desired that preventive medicine should cease making war upon the microbe, provided at the same time that other selective agencies are used to replace them. Is it not our duty, by boldly facing facts and publicly stating them, to endeavor to bring about such strong public opinion as will force people to look upon the act of giving birth to a diseased child as one of the most cruel sins?"

Having considered the position of the criminal and incapable classes, carefully separating the deserving poor, whose misfortune was treated with kindly sympathy, the Milroy lecturer concluded his course with his suggestion for improving the race—and here it must be confessed he did not push to their logical conclusion the statements he had submitted. The complexity of social problems is too great for the biologist. We cannot prevent marriage—we might perhaps segregate for life the habitual criminal as we do the dangerous insane. But how can we say to the consumptive, the delicate, the non athletic—some of them the most attractive, the most intellectual members of the race—you shall not marry, because you are not robust? Our biologists and Darwinians tell us your physical inferiority will deteriorate our race, and the lecturer at the College of Physicians indorses their statements. Might not the frail thinker reply: Well, the strong of body have ever been the tyrants; set up your standard and secure a fine breed of men from the animal side, but know for all that, your boasted improvement of the race may not be progress; the animal is not all the man, big bone and hard muscle do not imply powerful brains; ancient giants and modern strong men have not done much for your race, poets and philosophers from their sick-beds have given "thoughts that run and words that burn," the influence of which is better than all the doings of the burly sons of Anak. As for the doctors, some of the very best of them are fragile fellow-sufferers, and if you like I will give you a list of the dead or the living who have been or are neurotics, consumptives, or otherwise fragile of body, but grand contributors to human happiness.

Professor Haycraft properly called attention to the slovenly use of the word "poor," and said that in the scriptures it obviously means the deserving and unfortunate, but certainly not the habitually idle and vicious. He quoted with approval on this point, St. Paul's, "if a man will not work neither shall he eat," and "he that does not provide for his own house is worse than an infidel." Yet the apostle's physique would not have met with the approval of Darwinian biologists, for he tells us himself that his "bodily presence was contemptible;" and how much poorer would the race have been without this grand thinker. How can the followers of Him who came to seek and save the lost, abandon their work and give up the effort to reclaim the vicious and raise the lowest? It is right to say the lecturer did not ask this, and guarded himself against some other deductions; but the trend of the argument is in this direction, and the conclusion, to look to public opinion as the selective agent which must replace the microbe is, to say the least, feeble, even if reinforced by legislation, as was in fact suggested; for he declared that when the consequences of transmission to the offspring are realized, if the feeble and diseased marry "they will do so in face of public opinion—perhaps of public rule." He thinks that when the public conscience is aroused on the subject, the sickly and feeble will, with difficulty, find mates, and selection in the form of marriage will play a more important part, having more largely in view the quality of the progeny. Pride of family and race we have, and he would see more of it, but on a biological footing; "marriage not with a view to the amassing of acres, but for the perpetuating of fine physique;" and on these lines he believes we may reasonably expect to see an improvement in the well-being of the race.

He concluded the course as follows: "Man's present surroundings may safely be improved, and the sickly may have a longer life, but this consideration to the individual can only be given provided the race continues to be produced from the most robust and capable."

Now if this be so, are we not in a desperate case, considering in what a miserably diseased and degraded state we are to be in another one hundred years, according to the previously stated estimate? For the action of public opinion is very slow, as is the effect of selection itself. Most of us have been asked often enough by engaged persons as to the wisdom of the contemplated marriage, but few will deny that advice offered is seldom followed; on the contrary, those who ask have usually made up their minds to follow their inclination. Marriages, say lovers, are made in heaven, and it is futile to expect that the opinions of biologists, even if reinforced by the whole faculty of medicine, will in a single century subvert the practice of all the ages. The biologists, therefore, may as well resign themselves to the deterioration they predict, and plume themselves that when their prophecies are fulfilled there will be no Darwinians to take up the burden.

THE EYE-TREATMENT OF EPILEPSY.

To the Editor of the Medical Record.

Sir: In your issue of this date an editorial headed "The Treatment of Epilepsy by Glasses," concluded with the following paragraph:

"Curiously enough, Mr. Dodd seems to be quite unaware of the extensive labors of American ophthalmologists and neurologists upon this subject. And he does not refer at all to the muscular conditions of the eye, upon which so much stress is laid by some. Still *his results seem to be just about as* good *as those obtained by the* use of *prisms and tenotomies*." (Italics my own.)

As this editorial follows closely upon an extended and critical review of this field in medicine published by myself in the *New York Medical Journal* (January and February, 1894), and as it contains a criticism of Mr. Dodd's work very similar in tone to paragraphs in my own article, I trust I may be allowed space in your journal for a reply to what I deem an unwarranted conclusion respecting the results that have been obtained in epileptics by the "eye-treatment" alone.

In the first place, of the twenty-five clinical histories reported by me with full details of the treatment employed, *not one patient took bromides* while under the eye-treatment. (All of Mr. Dodd's cases seemed to have continued the use of bromides.)

Again, most of the cases reported by me were *chronic cases that had been drugged with bromides for years without any curative effects* upon the epilepsy, and with decided detriment to the general health, in many instances.

Thirdly, in some of the cases reported by me, all attempts to discontinue the use of bromides (prior to the correction of muscular anomalies of the orbit), had been followed by such an alarming increase in the fits as to necessitate an immediate return to the bromides. *After the correction of the eye-muscles, the withdrawal of bromides was not followed by any alarming results.*

Fourthly. It can hardly be called a purely accidental occurrence, or a fortuitous circumstance, when a patient having an average of ten attacks daily under bromides, enters upon his second year of entire freedom from attacks without bromides or other drugs after "eye-treatment;" when another victim to epilepsy and bromides for twenty-four years, enters upon his seventh year without epileptic seizures and the withdrawal of all drugs; when a third case continues in perfect health without drugs, when in the past a padded room was needed in which to place him during his violent paroxysms; and when a fourth patient, who required a constant attendant when under bromides, is now entering upon his fourth year of perfect health without drugs, was lately married, and has been for three years an active partner in a large business house.

It is needless to multiply examples of this kind here, to demonstrate that eye-treatment can and often does afford marked and permanent benefit in epilepsy. The

literature of this subject is sufficiently extensive to day, I think, to demonstrate that the reflex causes of epilepsy and other kindred neuroses are worthy of investigation and removal.

Respectfully yours,

AMBROSE L. RANNEY, M.D.

April 7, 1894.

THE ROYAL VICTORIA HOSPITAL, MONTREAL, CANADA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Recently the old time and historic city of Montreal celebrated its two hundred and fiftieth anniversary. That event, and the formal opening of the Royal Victoria Hospital in that city in December last, have made the year 1893 particularly memorable for Canadians. On June 20, 1891, the foundations were laid for the large buildings now known under the collective name of the Royal Victoria Hospital.

The inception of the idea of an hospital on a large scale is interesting. In 1887, or the queen's jubilee year, Lord Mount Stephen, then Sir George Stephen, and Sir Donald Smith, of Montreal, agreed to found an hospital, by the truly princely gift of $500,000 each, or $1,000,000.

The city of Montreal gave a site at the base of Mount Royal, or above Sherbrooke Street—not far from the many buildings composing the University of McGill College—the latter an educational centre under royal charter, that has steadily grown in importance and strength under the able guidance of Sir John William Dawson, C.M.G., F.R.S., etc. The bequests to McGill within a few years are estimated at $2,000,000. The site donated by the city was not large enough for the purposes of three main buildings and outbuildings. The founders again came to the front and purchased from private proprietors adjoining properties to the value of $86,000, when a large and perfect site was the property of the hospital. The location is a classic one; from it a perfect view may be had of Maisonneuve's old city, to-day with a population nearly three hundred thousand, the noble St. Lawrence, the islands in the river, the Victoria Bridge, and the distant Lachine rapids.

An act of incorporation was secured in 1887, when the Royal Victoria entered on its legal existence with the necessary board of directors, etc.

The founders are both Scotchmen by birth, but Canadians and Montrealers. They have amassed large fortunes in Canadian trade and enterprises. They wisely determined to make their gift during their lifetime, when they in person could see that their wishes were given form and substance.

The Royal Victoria Hospital, happily named in commemoration of Her Britannic Majesty's jubilee year, 1887, or the fiftieth anniversary of her reign, consists of three large and separate buildings, as well as a series of outbuildings. The main buildings are built of the fine blue limestone for which the island of Montreal is famous; as seen from the city the buildings appear as one. They cover three sides of a large square, with the usual central court or entrance. The central building faces the city and has two buildings, practically wings, built at right angles to it.

The buildings are as nearly fireproof as skill and science can make them, but to reduce all fire risks to a minimum, the separate or detached building has been adopted, to make "assurance doubly sure."

The central building is the administrative block, occupied solely by the resident staff for residences, offices, etc. The wing toward the east, or toward McGill University, is the medical wing or side, while that opposite, to the west, is exclusively surgical.

The architecture is exceedingly picturesque, and the effect is greatly enhanced by the commanding site occupied by the buildings. The style selected was Scottish baronial. The façade of the main building resembles that of Fyvie Castle, in Aberdeenshire, near Haddo House, the seat of Lord Aberdeen, the present popular and indefatigable Governor General of Canada. The round towers flanking the wings not only recall Scotland, but fair Normandy. They add a quaintness that is novel and attractive in this New World of ours; while they increase the architectural effect, their interiors are useful, as will be shown.

The designer was Mr. Henry Saxon Snell, F.R.I.B.A., of London. In Great Britain, and abroad, Mr. Snell is a recognized authority on hospitals and hospital construction. He built the St. Marylebone Hospital, London, accommodating six hundred patients, an hospital in Aberdeen, as well as others in the United Kingdom. It is said that Mr. Snell's long and honorable career, owing to age, is advancing to a close, and that in the Royal Victoria Hospital he has concentrated all his skill, experience, and knowledge, in a building worthy of its noble founders, a credit alike to the city of Montreal and the broad and prosperous Dominion of Canada.

The main building is connected with the wings by bridges. A description of a single ward will suffice for all, as they are nearly identical in general appearance. Let us consider one in the western or surgical wing. It is a long narrow room, with a lofty ceiling. The walls are white and hard, polished floor. Broad windows on both sides, or due east and west. They admit abundance of light. The windows are specially devised for thorough ventilation without draft. The ward contains thirty-two cots or beds, all of the latest hospital pattern. Beside each is a table of iron and glass. Ward heated by steam. The heating and ventilating apparatus in the walls provides for a constant stream of pure air from without, heated within, and again ushered outward. No foul air is possible. Length of ward, 125 by 27 feet. In the surgical wing, now under consideration, there are three wards of the above type. There are three in the east or medical wing. Apart from these there are private wards, medical and surgical, and an admirable ward for children on the medical side.

The four flanking towers, making the front ends of the wings, are divided up for bath-rooms, closets, etc. Each ward has a nurses' kitchen, where warm food may be had at any hour. Every inch of space has been utilized.

The enemy of man, as well as of medical and surgical science, the germ, that hopes to propagate in the Royal Victoria, certainly has calculated without his host; there his disease-producing and death-dealing mission has had special consideration. No habitat has been provided for him; the wards are without corners where dust and germs may lodge. The floor rounds up to the hard-finnished walls, and the walls round up to the ceilings above, and the walls round to each other. The whole admitting of instant and perfect cleaning—cleaning in the extended sense of modern sanitary science. No lurking place for germs anywhere. The iron and glass tables are constant reminders that germs and the Royal Victoria have nothing in common, the hospital's watchword is unrelenting hostility to germs of all kinds.

The operating theatre will seat three hundred students. It is in strict keeping with everything else in the building. A huge pane of glass, 8 by 20 feet, makes the window or opening opposite the operating-table; the room may be lighted by electricity.

Any extended notice of this, the latest of modern hospitals, is impossible, owing to the space allowed me. All that experience, sound judgment, sanitary science call for, are in evidence in the buildings. Ventilation perfect, without draft, an abundance of sunlight. The buildings have elevators in the wings for patients, bed and all if necessary, and an elevator to the hospital kitchen. The latter, just under the roof, can cook for a regiment. The buildings have the electric-light system, as well as a perfect system of telephones, the latter connecting every part with every other part, and all with the administrative building A concrete system in strict keeping with

all the advances in medical and surgical science, under the guidance of sanitary knowledge—the latter, a *sine qua non*. The whole, a harmonious blending of our *fin de siècle* knowledge.

The Royal Victoria was formally opened with appropriate ceremonies early in December. It did not receive patients until January. The Governor-General of Canada opened the building; he was accompanied by Her Excellency, Lady Aberdeen, who nobly seconds His Excellency in all that advances Canadian interests, and the bettering of mankind.

While it is true that cities larger than Montreal have larger hospitals, the Royal Victoria to day stands second to no hospital in the Old World, or the New. There Canadian students will be educated in our truly noble calling. A mission common to physicians and surgeons the world over—that noble brotherhood devoid of nationality—a mere amplification of the work of the Great Physician, or "that which He, who suffered with and for man, commanded His disciples to practise, when He sent them out into the world to carry out the work He laid the foundation of."

The names of Lord Mount Stephen and Sir Donald Smith will become a part of the present and of the future, as men whose work will be a perpetual benefaction to the sick and suffering. May their noble example find many followers here as well as in Canada.

The *Montreal Gazette*, from which this article, in a large part, has been compiled, intimates that the noble and titled founders have intimated their intention of endowing what they have created.

Wolfred Nelson, C.M., M.D., F.R.G.S.
New York.

Small-pox	24	5
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

What Becomes of Women Medical Students.—A correspondent of *The Lancet* writes as follows on this subject: The figures quoted from the *Revue Scientifique* with regard to lady medical students at Geneva, have led me to examine the statistics of the London School of Medicine for Women, and the comparison may not be without interest. In the first fifteen years from the foundation of the school, 1874 to 1888 inclusive, 190 students entered for the full course. Of these, 159 have qualified, 32 abandoned their studies, and 9 are still students. Of the students who entered in the two following years, 1889 and 1890, the majority have not yet had time to qualify, but the statistics are as follows: 64 students entered—6 of these have fallen from the ranks, 7 have already qualified, and the remainder are still working for their examinations. Thus, in all, 38 students, or fourteen per cent. of the whole number, have given up work—14 did so on their marriage, 6 from ill-health, and the remaining 18 for various reasons. Of the 166 students who have qualified, 9 have died, 129 are known to be in practice, and 28, or about fourteen per cent., have relinquished their profession. It would be interesting to know what relation these figures bear to those of other medical schools. In Sir James Paget's well-known article, "What becomes of Medical Students?" in St. Bartholomew's Hospital Reports, I find that of the 1,000 students whose history has been investigated by him, eight per cent. never qualified, and at least eight per cent. of those who qualified left the profession within twelve years. These percentages are, it is true, considerably smaller than the corresponding ones for the London School of Medicine for Women, but, considering the different conditions which apply to women, and how frequently marriage or the claims of relations are impediments to further progress, it can hardly be said, whatever may be the case at Geneva, that women medical students in England are lacking in steadfastness of purpose or devotion to the work they have undertaken.

Statistics of the Profession.—The British "Medical Directory" for 1894, gives the following as the numbers of the medical profession for the year 1894: In London, 5,590; in the provinces, including Wales, 14,897; in Scotland, 3,107; in Ireland, 2,485; registered practitioners resident abroad, 3,209; Naval, Military, and Indian Medical Services (excluding those which appear also in other lists), 2,426; "too late" list—additional names, 58. The total number of practitioners in the "Directory" for 1894 is 31,772, as against 30,759 in the previous year. This shows an increase in the twelve months of 1,013. The obituary list, which seems to be wonderfully complete, gives the deaths as 639. The above figures give one medical practitioner in London for every 750 of the population; in the provinces, one in 1,650; in Scotland, one in 1,300; in Ireland, one in 1,900; and in the United Kingdom generally one in 1,450. According to the official statistics published recently in Austria, there were in that country 6,057 physicians holding the diploma of M.D. in the year 1891, and 6,565 in 1892. In the former year there were also 1,588 surgeons of the old surgical schools, but in 1892 this number had been reduced by death to 1,582. The total number of medical practitioners in Austria in 1892 was 8,097, against 7,645 in 1891. The figures for 1893 have not yet been published. According to the *Annuario Statistico Italiano*, under the authority of the general direction of statistics at Rome, the total number of medical practitioners in Italy in 1892 was 19,120, being a proportion of 6.2 per 10,000 of population. The ratio varied in different parts of the kingdom, from 11.1 per 10,000 in sixty-nine chief towns of provinces, to 5.3 in the rural communes. The following figures show the number of practitioners and the proportion to population per 10,000 in several of the principal cities: Rome, 510 (11.6); Naples, 1,506 (28.3); Milan, 374 (8.8); Turin, 292 (8 8); Palermo, 225 (8.2); Genoa, 255 (12.0); Florence, 258 (13.1); Bologna, 144 (10.2); Venice, 127 (8.5); and Catania, 114 (9.5). Between 1878 and 1892 the absolute number of doctors increased by rather more than 1,000 (19,120 as against 18,044), but the relative number decreased from 6.5 to 6.2 per 10,000 of population. It is quite clear from these figures that in no part of the world is the proportion of physicians to the population as great as in the United States.

The Czar's Physician.—Since the death of Professor Botkin, of St. Petersburg, the title of the "first physician in Russia" has been transferred by the public to his old rival, Professor Zakhärin, of Moscow. The latter is in every respect a very interesting personality. He is now about sixty-five years of age, and has been professor of clinical medicine in the Imperial University of Moscow for the last thirty-five years. He received his medical education in Russia, afterward completing it by visiting some of the German universities. He was the first in Russia to introduce exact clinical examination and treatment, and he very soon acquired a large and important practice in the Old Capital of Russia. So successful has he been that he is believed to be worth 5,000,000 roubles

(half a million sterling), the bulk of which has been earned by the practise of his profession. Zakhärin has not written much. He has throughout his career chiefly concerned himself with the practical side of medicine, and especially with the details of treatment. To his consulting-room patients are sent by their medical attendants from all parts of Central and Southern Russia and from Siberia. Success, however, has engendered some peculiarities of character, or perhaps rather of manner, in Professor Zakhärin, which, though possibly in place in Russia, would hardly be suited for other countries. He is fond of showing his power in a manner which is sometimes inconvenient to the people who require his services. Special arrangements must be made in every house in which he sets foot; all dogs must be kept out of the way; all clocks must be stopped; all doors must be thrown wide open. The professor on entering begins a process of gradual undressing, leaving his furs in the hall, his overcoat in the next room, his goloshes in the third, etc. He insists on perfect silence on the part of the afflicted relatives, except in reply to his questions, when their speech must be literally "Yea" and "Nay." His demeanor toward practitioners with whom he happens to be unacquainted makes him greatly feared by them. The learned professor is a man of many "humors," as Ben Jonson would have called them. His fear of over-exertion almost amounts to a monomania. He has a theory as to idiopathic hypertrophy of the heart, which forms a rule of life for him. A maxim which he is fond of repeating is "Take a rest before you are tired," and accordingly he sits down every eight or ten steps. His eccentricities have naturally been the subject of a good deal of unfriendly comment, and some eight years ago a kind of public agitation was got up in opposition to him, in which many hundreds of doctors took part. Resolutions were passed and addresses were presented, and echoes of the gathering storm made themselves heard in the press. These manifestations of feeling were speedily repressed in a way characteristic of Russia. The then General-Governor of Moscow, Prince Dolgoroukoff, sent for the editor of the medical journal in which the addresses were printed, and told him that if he published a word more about Zakhärin he would have to leave Moscow in twenty-four hours' time. It must be admitted, however, that this medical despot can be as courteous and considerate to his patients as possible if he likes, and certainly he is very thorough in his methods of treatment. He never orders or prescribes anything—except, of course, in urgent cases—unless he knows his whole past, his mode of life, his habits, his diet, and his whole social environment, and often by a trifling change in the habits he cures a very chronic ailment. He keeps his patient often two or three hours under examination, and he never sees a patient without a doctor, even if he comes from a distance, and he never prescribes himself. Zakhärin is an individualist; he has no printed diet sheets, and no cut and dried prescriptions: every case is treated in accordance with its particular circumstances.—*British Medical Journal.*

Incompatibles.—Dr. James Kennedy, Professor of Pharmacy, University of Galveston, Tex., says: "A mixture of antipyrine and nitrous ether will deposit green crystals if allowed to stand, providing there is not sufficient water present to keep the new substance in solution. Acetate of lead and sulphate of zinc are frequently ordered in combination for use in the treatment of inflammatory affections of the genital mucous membranes under the impression that the constringing power of these drugs is enhanced by so doing. This is a mistake. Double decomposition occurs when these two salts are dissolved together; sulphate of lead is precipitated as an inert substance, while the acetic acid is transferred to the zinc to form zinc acetate. Strychnine is sometimes prescribed in combination with the bromides or iodides. This is a dangerous practice, for the reason that after the mixture has been allowed to stand for some time the bromide or iodide of strychnine will crystallize and be deposited in the bottom of the vial, and as the last dose of the medicine is taken the greater portion of this powerful drug contained may be swallowed, and perhaps with fatal results. Illustrations of chemical incompatibility might be multiplied *ad infinitum*. The following rules should be borne in mind: Acids should never be prescribed with alkalies or their carbonates. Alkaloids should never be prescribed in combination with alkalies or alkaline carbonates. Salts of the alkaline earths, *i.e.*, magnesium, calcium, barium, and strontium should not be prescribed with soluble carbonates, tartrates, or oxalates, and in the case of the three latter elements they should never be combined with soluble sulphates, phosphates, arsenates, phosphoric or sulphuric acid. The heavy metals, such as iron, manganese, lead, mercury, silver, and zinc should never be prescribed in conjunction with the alkalies, their carbonates or oxalates. Silver should never be prescribed in combination with chlorides, bromides, iodides, or hydrochloric acid or organic matter (substances of vegetable or animal origin). The soluble salts of lead should never be combined with chlorides, hydrochloric, hydrobromic, hydriodic or sulphuric acid."

Vinegar as a Remedy Against Vomiting After Chloroform Narcosis.—Immediately after having performed the operation and placed the patient in bed, Warholm applies a handkerchief moistened with vinegar in front of the nose, letting it remain there until the patient returns to consciousness, or longer if it agree well with him. Of thirty cases experimented upon by the author, the majority were benefited. In most of them the effect was absolute. In two cases the remedy did not succeed; one of these was an alcoholist. The patient should also have a small phial, filled with vinegar, standing at his bedside, to smell as the demand arises. *Hygiea*, lv., 10, Stockholm, 1893.—*The Clinic.*

The Charities of London.—According to the nineteenth annual *Directory to Metropolitan Charities*, over $27,000,000 are spent in a year in carrying on the work of 759 societies and institutions. Of these latter there are 206 in which the medical profession is interested. Their respective number and object, together with their income stated in English values, are given as follows: "Twenty-five charities for the blind, £74,299; seven charities for deaf and dumb, £20,565; five charities for incurables, £51,527; two charities for idiots, £59,165—£205,556. Sixteen general hospitals, £351,247; eight consumption hospitals, £70,235; five ophthalmic hospitals, £15,876; three orthopædic hospitals, £5,462; five skin hospitals, £8,487; sixteen hospitals for women and children, £88,825; four lying in hospitals, £13,942; twenty-nine miscellaneous special hospitals, £119,884—£673,958. Twenty-nine general dispensaries, £29,083; thirteen provident dispensaries, £9,321; six institutions for surgical appliances, £38,599; twenty six convalescent institutions, £64,449; seven nursing institutions, £11,708—£153,160."

Castration of Sexual Perverts.—Dr. F. E. Daniel concludes a paper on this topic as follows: While we cannot hope ever to institute a sanitary utopia in our day and generation, it would seem within the legitimate scope and sphere of preventive medicine, aided by the enactment and enforcement of suitable laws, to eliminate much that is defective in human genesis, and to improve our race mentally, morally, and physically; to bring to bear in the breeding of peoples the principles recognized and utilized by every intelligent stock raiser in the improvement of his cattle; and in my humble judgment the substitution of castration, as advocated above, for the useless and cruel execution of criminals, is the first step in the reformation. I predict that in twenty years the beneficial results of castration for crimes committed in obedience to a perverted (diseased) sexual impulse will be established and appreciated. Rape, sodomy, bestiality, pæ-

derastia, and habitual masturbation should be made crimes or misdemeanors, punishable by forfeiture of all rights, including that of procreation; in short, by castration, or castration plus other penalties, according to the gravity of the offence. It is to be hoped that the medical profession will no longer neglect the investigation of a psychological state fraught with so much significance to criminal jurisprudence. The meaning of every phase of perverted sexuality should be understood, not only by physicians, but by jurists. A more free and unreserved intercourse between the two learned professions should be fostered, when, with a better understanding of the subject in its relation to crime, they can co-operate to secure a modification of existing unsatisfactory laws, and the enactment of others consonant with a more advanced state of medico-legal knowledge. This we owe to ourselves, if we would not merit reproach; to posterity, if we would secure to future generations the full fruits of sanitation in the practice of the great science of preventive medicine.—*Daniel's Medical Journal.*

A Certain Sign of Death.—M. Nicati has invented an ophthalmotonometer, by the aid of which he has discovered that the tension of the globe of the eye, which is normally from eighteen to twenty one grammes, may oscillate, in the physiological state, between fourteen and twenty-five grammes (T. = 0.4 to 1). This tension diminishes with the cessation of the heart beats to twelve grammes, and the lowering of tension, interrupted by rebounds never exceeding twelve grammes, is afterward progressive, until after the lapse of half an hour it has sunk to from one to three grammes. In two hours it is *nil.* The enucleated eye replaced in the orbit presents the same phenomena. The usefulness of this method in medico legal medicine is self evident, and M. Nicati claims for his instrument a further field of usefulness in general medicine, seeing that it can be employed in determining the blood pressure, the amount of which always bears a constant relation to that of the aqueous humor.

A New Clinical Society.—The staff of the Brooklyn Central Dispensary has organized a clinical society, for the purpose of holding a monthly interchange of views on medical and surgical subjects. Reports of the more important cases occurring at the dispensary clinics will be presented and preserved. The name of the organization is the Central Clinical Society of Brooklyn. Among the members are Dr. Barber, Dr. Lucas, Dr. Yorke, Dr. Anderson, Dr. Cochrane, Dr. Jelliffe, and Dr. Wood. The meetings will be held on the fourth Thursday of each month.

Muller's Fluid. T. R.—This fluid, which is perhaps the most commonly employed liquid for hardening pathological specimens, is made by the following formula:

Potassium bichromate	2 parts.
Potassium sulphate	1 part.
Water	100 parts.

The Relation of the Medical Profession to the Abolishment of Prostitution.—In a paper read before the Military Tract Medical Association, Dr. J. F. Percy, of Galesburg, Ill., discusses the causes of prostitution, and gives his views as to the attitude which the medical profession should take toward it. He says: "There can be but one answer to this question. Reform the individual. But when the individual is ignorant of the fact that he needs reforming, what are we to do? Enlighten him! And who can do this but medical men? If we look at this subject from every possible point of view, individual reformation will be found to be the most important means through education of throttling this great public shame which permits of the enslavement of women, and, at the same time, protects the libertinism of men. In other words, 'we must pay more attention to the individual; to the private conscience.' That public agitation of questions like this is of value when rightly presented, I will not deny. But it must be done by men and women who are qualified first by a deep knowledge of the subject, combined with a practical common sense that will be explicit enough to leave no doubt of the meaning intended, yet so guarded as not to offend in its application; above all, there must be a deep and pure love of all that is best for the human race. First, then, individual reformation is to be accomplished, whenever opportunity offers, by a process of pure education on all matters relating to sexual life. Again, to do all possible to establish a custom that will, at least, 'care for our young until after eighteen years,' for before that time thoughtless ignorance and blind impulse of the physical beings are generally stronger than their intellectual and moral faculties. And in this line I plead with you to do all possible to change the pernicious fashion in our American life that permits the mischievous relations between the sexes after the engagement, which is supposed to be the prelude to a happy and healthful marriage. The American parlor after dark is the open door to the possibility of all forms of sexual excess. Young women, leaders in our prayer-meetings, shining lights in the Christian Endeavor Societies, do not think it wrong to sit in the laps of their best young men until the small hours of the morning. They do this under the mistaken, but hellish notion that it is love. Our relation to its abolishment comes into the line of our individual duty as educators, and in no one thing is our responsibility greater. I refer to what the French, who, when they speak of American women, hold up their hands in horror, pointing the finger of scorn at what they are pleased to call the American sin, viz.: abortion. On the other hand we, in America, have only a contempt for our sister who lives across the broad waters when we hear of the number of her illegitimate children. The measure of the sin in its inception is the same in both cases. The difference is that in our own case the innocent life is destroyed before our neighbors know of its existence, while with our sisters in France the life is not destroyed at all. We have not done our whole duty, when we refuse to produce an abortion. We must educate the world up to the point where it will know that to do a thing like this is a most heinous crime. 'Physicians meet in practice women who would scorn to speak evil against a neighbor, who are tender and kind, leaders in social and even religious life, who are above suspicion as to chastity, yet who do not hesitate to murder their own children, providing only they be small enough They do this not only once but repeatedly; and not only do they commit this crime, but talk about it very unconcernedly, or engage in disseminating a knowledge of the work among friends as earnestly as they would work for a supper for the benefit of a hospital, kindergarten, or the far-distant heathen. They would fear to reverse the hands of their watch, but would break the laws of nature in their own human mechanism, a hundred-fold more delicate, complicated, and precious.'

And in the distressing cases where, through ignorance, some girl, confiding in the promises of the fellow she has been taught by custom to call her lover, is betrayed, let us remember that there are State laws that will look after the betrayer, to protect her, and it is our duty to give this information. I know of a number of happy homes, as the world goes, that have grown out of compulsory marriages like these. Again, to abolish prostitution from our land, let us strive with all the power of our might to break down that hellish idea that because a woman has once stepped from the paths of virtue, she has no more claims on our sympathetic charity. This kind of Puritanism has driven and is driving scores of women into the ranks of prostitution."

A Sick Chinaman Never Sneezes.—Dr. Lucy H. Hoag, of Chinkiang, China, writes: "The question was recently discussed in THE RECORD in a humorous way, 'Do sick people ever sneeze?' It is a generally accepted belief among the Chinese that a very sick person never sneezes, simply because the nasal passages are occluded. I add this to the collection of items for what it is worth."

DIGESTIVE PROTEOLYSIS.

THE CARTWRIGHT LECTURES FOR 1894.

BY R. H. CHITTENDEN, PH.D.,

PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN YALE UNIVERSITY.

(Continued from page 453.)

LECTURE II.

PART I.—PROTEOLYSIS BY PEPSIN-HYDROCHLORIC ACID.

GASTRIC digestion is essentially an acid digestion. As a proteolytic agent pepsin can act only in the presence of acid, and we have every reason for believing that the enzyme and the acid form a compound, which in turn combines with the proteid undergoing digestion; or, what amounts to much the same thing, that the acid perhaps forms first a compound with the proteid, to which the pepsin can then unite to form a still more complex compound capable of undergoing hydration and cleavage. Pepsin-proteolysis, therefore, is strictly the proteolysis produced by pepsin-acid. In view of this fact, we may well give a moment's thought to the nature and origin of this acid.

Without attempting any statement of the gradual development of our knowledge regarding the acid of the gastric juice, we may accept the now well-established fact that the acid is hydrochloric acid, and that it has its origin in the parietal, or so called border-cells of the gastric glands. That the acid is derived from the decomposition of chlorides is practically self-evident, but Cahn[1] has added experimental proof which removes all shadow of doubt, through his study of the gastric secretion in animals deprived for many days of salt; the gastric juice in such cases being perfectly neutral in reaction, but normal as regards its content of pepsin.

The way in which the specific gland-cells manufacture free hydrochloric acid out of material contained in an alkaline medium is somewhat doubtful. There are, however, at the present day two theories worthy of special notice. The first is based upon observations made by Maly[2] many years ago, which tend to show that certain mineral salts present in the blood are capable of reacting upon each other with formation of hydrochloric acid. Thus, while the blood is an alkaline fluid, it really owes its alkalinity to the presence of two acid salts, viz., sodium bicarbonate ($HNaCO_3$) and disodium hydrogen phosphate (HNa_2PO_4). This latter compound, acted upon by the carbonic acid of the blood, is transformed into a dihydrogen sodium phosphate with simultaneous formation of acid sodium carbonate, as shown in the following equation:

$$Na_2HPO_4 + CO_2 + H_2O = NaH_2PO_4 + HNaCO_3.$$

This acid sodium phosphate dissolved in a fluid containing sodium chloride, gives rise to free hydrochloric acid by a very simple reaction:

$$NaH_2PO_4 + NaCl = Na_2HPO_4 + HCl.$$

It is also to be noted that the disodium hydrogen phosphate may, likewise, give rise to hydrochloric acid through its action on calcium chloride, as indicated by the following equation:

$$2\,Na_2HPO_4 + 3CaCl_2 = Ca_3(PO_4)_2 + 4NaCl + 2HCl.$$

It is thus evident that hydrochloric acid may originate in the inter-reaction of these several salts which are known to be present in the blood; but obviously, the above reactions cannot take place in the blood itself, and we must look to the selective power of the epithelial cells of the gastric glands, as suggested by Gamgee,[1] for the withdrawal of the needed salts from the blood. Once present in the acid-forming cells, and perhaps aided by the inherent qualities of the protoplasm, the necessary chemical reactions may be assumed to take place, after which the newly formed acid may pass from the gland cells into the secretion of the gland.

A later theory regarding the formation of the acid of the gastric juice emanates from Liebermann.[2] This investigator claims the existence in the mucous membrane of the stomach of an acid-reacting, nuclein-like body, which is apparently a combination of the phosphorized substance lecithin with a proteid. To this compound body Liebermann gives the name of lecithalbumin. It is apparently located in the nuclei of the gastric-cells, is strongly acid in reaction, and, according to Liebermann, is an important agent in the production of the free hydrochloric acid of the gastric juice, although its action is somewhat indirect. According to this theory, the free acid is formed in the mucous membrane of the stomach from sodium chloride, through the dissociating action of the carbonic acid coming from normal oxidation. The thus formed acid then diffuses in both directions, viz., through the lumen of the gland into the stomach cavity, and in part in the opposite direction into the veins and lymphatics. It is the assumed function of the lecithalbumin to react with the alkaline sodium carbonate, produced simultaneously with the hydrochloric acid. This naturally gives rise to the liberation of carbonic acid and to the formation of a non-diffusible sodium-lecithalbumin compound, which is retained for the time being in the body of the cell. When the circulation of the blood, accelerated by the digestive process, returns to its ordinary pace, this latter compound is slowly decomposed by carbonic acid with formation of the readily diffusible sodium carbonate, which passes into the blood-current. The rate of this latter reaction is impeded, or perhaps regulated, by the swelling up of the lecithalbumin-containing cells, thus rendering the imbibition of the carbonic acid a slow process. The rate of production of the hydrochloric acid by this hypothetical process depends primarily upon the blood supply, and the oxidative changes by which carbonic acid is formed.

There is much that might be said for and against this theory,[3] but we cannot stop to discuss it here. Like the previous theory, it implies the production of hydrochloric acid from a chloride or chlorides, through chemical processes taking place in the stomach mucosa, and presumably in the large border-cells of the peptic glands. This hydrochloric acid, as you know, in the act of secretion, reacts upon the pepsinogen with which it may come in contact,

transforming it into pepsin. It also has the power of combining with all forms of proteid matter, not excepting the products of proteolytic action, to form acid compounds in which the so combined acid, although equal quantitatively to the original amount of free acid, is less active in many ways. Thus, it does not possess in the same degree a destructive action on the amylolytic ferments;[1] it does not play the same part in aiding the proteolytic action of pepsin, and its antiseptic power is far from equal to that of a like amount of free acid.[2]

With relatively large amounts of proteid, we may have half or even quarter saturated proteid molecules, in which the weakness of the combined acid is far more pronounced than in the case of the fully saturated molecule. Such a condition of things must obviously exist in the early stages of gastric digestion. With an excess of proteid matter in the stomach, some time must elapse before the secretion of hydrochloric acid will be sufficient to furnish acid for all of the proteid matter present, yet pepsin-proteolysis does not wait the appearance of free acid. Indeed, the proteid matter may not have combined with more than half its complement of hydrochloric acid before digestive proteolysis is well under way. I have made many analyses of the stomach contents after test meals, and under other conditions, where no free acid could be detected by the tropaeolin test, or better, by Günzburg's reagent (phloroglucin vanillin), although phenolphthalein as well as litmus showed strong acid reaction, and yet not only could acid-albumin be detected in the filtered fluid, but likewise proteoses and peptones. In other words, pepsin-proteolysis can proceed in the absence of free hydrochloric acid, although not at the same pace. Hence, proteoses and even peptones may make their appearance in the stomach contents at a very early period of digestion, *i.e.*, the final products of proteolysis may be found in a mixture containing even a large proportion of wholly unaltered proteid, and obviously at an early stage in the process. Expressed in other language, a portion of the first formed acid-albumin or syntonin may be carried forward by the digestive process to the secondary proteose and peptone stage, before the larger portion of the ingested proteid food has even combined with sufficient acid to insure the complete formation of acid-albumin. This introduces another factor, to be referred to later on, viz , the relative combining power of different forms of proteid matter, especially the proteoses and peptones, as contrasted with native proteids.

In proof of the statement that pepsin-proteolysis can proceed in the absence of free hydrochloric acid, provided combined acid be present, allow me to cite one or two experiments bearing on this point. A perfectly neutral solution of egg albumin, containing 0.8169 gramme of ash free albumin per 10 c.c. of fluid, was employed as the proteid material. In order to completely saturate the proteid contained in 20 c.c. of this neutral albumin solution, 50 c c. of 0.2 per cent. HCl were required. Two mixtures were then prepared as follows:

A. Twenty c.c. of the neutral albumin solution + 50 c.c. 0.2 per cent. HCl + 30 c.c. of a weak aqueous solution of pepsin, perfectly neutral to litmus. This mixture gave only the faintest tinge of a reaction for free acid when tested by Günzburg's reagent.

B. Twenty c.c. of the neutral albumin solution + 25 c.c. 0 2 per cent. HCl + 30 c.c. of the neutral pepsin solution. In this mixture, the proteid matter was obviously only half saturated with acid.

The two solutions were placed in a bath at 40° C., where they were allowed to remain for forty-four hours, a little thymol being added to guard against any possible putrefactive changes. At the end of this time the amount of undigested albumin was accurately determined. The 20 c.c. of original albumin solution contained 1.6338 gramme of dry coagulable albumin. At the end of the forty-four hours, *A* contained only 0.5430 gramme of unaltered albumin, or acid-albumin, while *B* contained 1.2225 gramme. That is to say, in the mixture *A*, where the acid existed wholly in the form of combined acid, but with the albumin completely saturated, 1.0908 gramme of the proteid were converted into soluble albumoses and peptones. In *B*, on the other hand, where the albumin was only half saturated with acid, 0.4113 gramme of the proteid was converted into soluble products. This difference in action is made more striking by the statement that where the proteid was only half saturated with acid, 25.1 per cent. of the albumin was digested; while with a complete saturation of the proteid, 66.7 per cent. of the albumin was digested.

To give emphasis to this matter, a second experiment may be quoted as follows: The proteid used was the same neutral solution of egg-albumin containing 0.8169 gramme of albumin per 10 c.c. Two mixtures were prepared as follows:

A. Ten c.c. of the neutral albumin solution + 21.7 c.c. 0.2 per cent. HCl, the amount needed to completely saturate the proteid, + 40 c.c. of a weak solution of pepsin, perfectly neutral.

B. Ten c.c. of the albumin solution + 10.9 c.c. 0.2 per cent. HCl + 40 c.c. of the pepsin solution, making a mixture half saturated with acid.

These two solutions were warmed at 40° C. for seventeen hours. The extent of digestive action was then determined, when it was found that in *A* only 0.1638 gramme of the proteid was undigested, while in *B*, 0.6088 gramme remained unaltered. In other words, where the proteid was completely saturated with acid, but with an utter lack of free acid, 79.9 per cent. of the albumin was converted into albumoses and peptone, while in the mixture half saturated with acid only 25.4 per cent. was digested.

These two experiments thus give striking proof that free acid is not absolutely essential for pepsin-proteolysis. Digestion is, to be sure, more rapid and complete when free hydrochloric acid is present, but proteolysis is still possible, and even vigorous, when there is a marked deficiency of free acid. Further, as we have seen, proteolysis may proceed to a certain extent even though the amount of acid available is not sufficient to combine with more than half the proteid matter present.

These facts at once raise the question whether the products of proteolysis may not have a stronger affinity for acid than the native proteids; an affinity so strong that they may be able to withdraw acid from the acid-albumin first formed. One of our conceptions regarding pepsin-proteolysis is that acid is necessary for every step in the proteolytic process. A primary albumose, for example, cannot be further changed by pepsin, unless there is acid present for it to combine with. This being true, it is clear, in view of the fact that even peptones may appear in a digestive mixture containing an amount of acid insufficient to combine even with the albumin present, that the products of proteolysis must withdraw acid from the acid-albumin first formed. In regard to the first point, my own experiments certainly tend to show that the products of gastric digestion do combine with larger amounts of hydrochloric acid than undigested proteids; and further, that of the several products of proteolysis, the secondary proteoses combine with a larger percentage of acid than the primary proteoses, while true peptones combine with still larger amounts. In other words, the simpler and more soluble the proteid, the larger the amount of acid it is capable of combining with; a statement which accords with results obtained by other workers[1] in this direction. Further, another factor of considerable importance in connection with the natural digestive process is that a dissolved proteid, such as protoalbumose for example, will combine more readily with free acid than an insoluble proteid: from which Gillespie[2] is led to infer that in pepsin-proteolysis where

[2] Loc. cit.

there is no free acid present, only acid-albumin proteoses may be formed to a limited extent at the expense of some of the acid of the acid albumin, a portion of the latter being perhaps reconverted into albumin. The ability of the proteoses, however, to withdraw acid from its combination with a native proteid is perhaps best indicated by Kossler's[1] experiments, which show that a solution of acid-albumin containing only enough hydrochloric acid to hold the albumin dissolved, on being warmed at 40° C. for some hours, with addition of a neutral solution of pepsin, may undergo partial conversion into albumose or peptone.

In spite of these facts, there is some evidence that while proteoses and peptones have the power of combining with more acid than a like weight of native proteid, the latter, leaving out all action of the pepsin, has a stronger affinity for the acid; in fact, the firmness or strength of the union appears to diminish as the products become simpler.[2] Hence, a peptone separated from a digestive mixture, will part with its combined acid somewhat more readily than acid-albumin for example, although on this point there is not complete unanimity of opinion.[3] In digestive proteolysis, however, where the pepsin is accompanied by a minimal amount of hydrochloric acid, insufficient perhaps to even half saturate the proteid present, the formation of proteoses and peptones must be accompanied by a withdrawal of acid from its combination with the native proteid.

In illustration of some of these points, and especially of the statement that the products of gastric digestion have the power of combining with more hydrochloric acid than the original proteid, allow me to cite the following experiment: 10 c.c. of a neutral solution of egg albumin containing about 0.82 gramme of pure dry albumin, free from mineral salts, required 23.8 c.c. of 0.2 per cent. hydrochloric acid to completely saturate the proteid matter. A mixture was then prepared as follows: 10 c.c. of the albumin + 24 c.c. 0.2 per cent. HCl + 30 c.c. of a neutral pepsin solution, the mixture showing a faint trace of free acid when tested by Günzburg's reagent. This solution was placed in a thermostat at 38° C., and from time to time a drop of the fluid was removed and tested for free acid. If no reaction could be obtained, 0.2 per cent. hydrochloric acid was added to the mixture, until Günzburg's reagent showed free acid to be again present. The following table shows the rate of disappearance of free acid, and the amounts of 0.2 per cent. HCl required to make good the deficiency. The mixture was placed at 38° C. on February 6th, at 11.30 A.M., and, as stated, contained a trace of free acid, 24 c.c. 0.2 per cent. HCl having been added to accomplish this result.

From these results several interesting conclusions may be drawn, in conformity with the statements already made. Thus, as soon as proteolysis commences, the products formed begin to show their greater affinity for acid by withdrawing acid from its combination with the native proteid, a supposition which is necessary to account for even the starting of the proteolytic process. Further, it is evident that proteoses and peptones combine with a far larger equivalent of acid than the native albumin is capable of: 17 c.c. of 0.2 per cent. HCl being required in the above experiment to satisfy the greater combining power of the newly formed products. This doubtless depends upon the cleavage of the large proteid molecule into a number of smaller or simpler molecules, each of the latter, perhaps, combining with a like number of HCl molecules. This view of the relationship of the individual proteoses and peptones is one more or less generally held, and is supported by many facts.[1] However this may be, it is evident that the products of pepsin proteolysis combine with a larger amount of hydrochloric acid than the mother proteid, and that the transformation of the latter, at least under the conditions of this experiment, is a slow and gradual process. In the living stomach, on the other hand, where the secretion of acid is progressing with ever-increasing rapidity, it is easy to see that the process of proteolysis would naturally be much more rapid.

Just here we may recall the theory advanced by Richet[2] quite a number of years ago that the acid of the gastric juice is a conjugate acid, composed of leucin and hydrochloric acid, a theory which has found little acceptance. Klemperer,[3] however, assumed that solutions of leucin hydrochloride with pepsin would not digest albumin, but Salkowski and Kumagawa,[4] have shown by experiments that leucin and other amido acids, as glycocoll, may be dissolved in hydrochloric acid, in such proportion that the solution is practically composed of leucin hydrochloride, without interfering with the digestive action of pepsin acid on blood-fibrin; the solution is physiologically active, although Günzburg's reagent shows an entirely negative result for free acid. If the matter is studied quantitatively, however, it will be found that the amido-acids combining in this manner with the hydrochloric acid of the gastric juice do give rise to some disturbance of proteolytic action;[5] *i.e.*, digestion may be less rapid, especially on egg-albumin, a conclusion which Salkowski[6] has lately confirmed. Still, under such circumstances, digestion does go on and at a fairly rapid rate; hence, if there is a combination between the acid and these organic bodies, as is indicated by Günzburg's reagent, the acid is still active physiologically, even more so than in the compound formed by the interaction of proteid and acid. In other words, many of these neutral organic bodies that may originate in the stomach through fermentation processes, or otherwise, and which tend to combine with the acid of the gastric juice, do not, as a rule, impede pepsin-proteolysis to the same extent that an excess of proteid matter may. In fact, in artificial digestions long continued, pepsin-acid solutions containing considerable leucin, for example, may accomplish as much in the way of digesting proteid matter as the same amount of pepsin-acid without leucin; but the inhibitory action of the amido-acid is there, and may be shown during the first few hours of the experiment, when less proteoses and peptones are formed than in the control experiment without leucin.

It is foreign to our subject to discuss here methods for the detection of so called free and combined hydrochloric acid in the stomach contents, or the special significance of such findings in health and disease. I cannot refrain, however, in connection with what has been said above, concerning the proteolytic action of pepsin in the presence of combined acid, from saying a word concerning the usual deductions drawn from the absence of free acid in the stomach contents. As Langermann[7] has re-

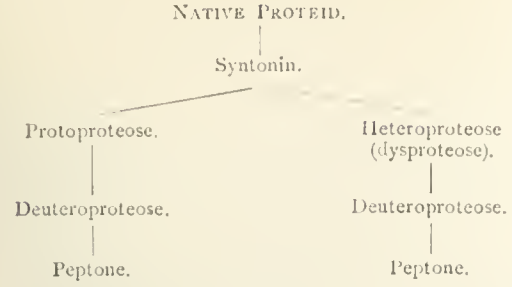
cently expressed it, we have methods for discriminating between free and combined acid; we can, moreover, determine the amount of free acid, but is it not equally important to be able to say something definite concerning the amount of combined acid in the stomach contents? Even in the absence of free hydrochloric acid there may be a sufficient amount of HCl secreted to answer all the purposes of digestion, and yet at no time may there be any free acid present to be detected by the various color-tests ordinarily made use of. I am aware that in ordinary examinations of the stomach contents after a test meal the results are essentially comparative, and possibly all that are necessary for clinical purposes. What I wish to emphasize, however, is that in order to pass conclusively upon the sufficiency or insufficiency of the gastric secretion, it is wise to know not only the total acidity of the stomach contents and whether there is free acid or not, but to know more about the amount of combined acid present. Thus, there is a natural tendency to divide the fluids withdrawn from the stomach into three groups, viz., those which contain free acid in moderate amount, those which contain free acid in excess, and those in which free acid is entirely absent; but in the latter group, there may be very marked differences in the amount of acid combined with the proteid and other material present. It appears to me that one of the questions to be answered is whether there is sufficient combined HCl present to meet all the requirements for digestion. If there is, that gastric juice may be just as normal as the one containing free mineral acid, and yet, according to our present tendencies, we should be inclined to call the juice containing no free acid abnormal, although there may be sufficient combined acid present to meet all the requirements for digestion. Hence, in examination of the stomach contents, it is well to consider the use of those methods which tend to throw light upon the amount of combined acid present, for in my opinion it is only by a determination of the total amount of combined acid that we can arrive at a true estimate of the extent of the HCl deficiency. Obviously, in simple clinical examinations of the stomach contents after a test meal, where proteid matter is not present in large amount, free acid may reasonably be expected to appear after a definite period; but in any event, it is well to remember that free hydrochloric acid is not absolutely indispensable for fairly vigorous proteolytic action, and that in the presence of moderate amounts of proteid matter a large quantity of acid is required to even saturate the albuminous material.

Consider for a moment the amount of acid a given weight of proteid will combine with. before a reaction for free acid can be obtained. Thus, Blum[1] has stated that 100 grammes of dry fibrin will require 9.1 litres of 0.1 per cent. hydrochloric acid to completely saturate it. Hence, with a daily consumption of 100 grammes of proteid, there would be needed for gastric digestion 4.5 litres of 0.2 per cent. hydrochloric acid daily, and even this would not suffice to give any free acid, assuming that none of the acid is used over again. The results I have already given for egg albumin tend to show that 1 gramme of pure albumin, free from inorganic salts, when dissolved in a moderate amount of water will combine with about 30 c.c. of 0.2 per cent. hydrochloric acid. Consequently, on this basis, 100 grammes of dry egg-albumin will combine with 3 litres of 0.2 per cent. HCl, and not until this amount of acid has been added to such a mixture will reaction for free acid be obtained with Günzburg's reagent. Hence we can easily see, in view of these figures, that the production of hydrochloric acid by the gastric glands may at times be very extensive, without the stomach contents necessarily containing free acid.

While I am by no means willing to agree with Bunge[2] that the chief importance of the acid of the gastric juice is its action as an antiseptic, I am decidedly of the opinion that the lack of free hydrochloric acid in the stomach contents is more liable to cause disturbance through the consequent unchecked development of bacteria than through lack of proteolytic action, assuming, of course, the presence of a reasonable amount of combined HCl. The hydrochloric acid of the gastric juice unquestionably plays a very important part in checking the growth and development of many pathogenic bacteria, as well as of less poisonous organisms, which are taken into the mouth with the food. On all, or at least nearly all of these organisms, free hydrochloric acid exerts a far greater destructive action than when it is combined with proteid matter. As Cohn[1] has plainly shown, both hydrochloric acid and pepsin-hydrochloric acid quickly hinder acetic- and lactic-acid fermentation, but when the acid is combined with peptone, for example, it is no longer able to exercise the same inhibitory influence. It is also important to note that the lactic acid ferment is not so sensitive to hydrochloric acid as the acetic-acid ferment. Consequently, when lactic-acid fermentation is once developed a comparatively large amount of HCl is required to arrest it. Hence, as we all know, a diminished secretion of hydrochloric acid renders possible acid fermentation of the stomach contents, as well as putrefactive changes which would not occur in the presence of free HCl, and which are very incompletely checked when the acid is over saturated with proteid matter.

Pepsin-proteolysis, however, may proceed, to some extent, at least, even though a small amount only of combined acid is present. The combined acid, however, must be hydrochloric acid, if proteolysis is to be at all marked. To be sure, pepsin will act in the presence of lactic acid, as well as in the presence of other organic acids and inorganic acids, likewise, but such action at the best is considerably weaker than the action of pepsin-hydrochloric acid.[2]



The ferment pepsin can exert its *maximum* action only in the presence of free hydrochloric acid. There must be sufficient HCl to combine with all of the proteid matter present, and the products of proteolysis as fast as they are formed, if digestion is to be rapid and attended with the formation of a large proportion of the final products of proteolysis. It is under such conditions that our study of pepsin-proteolysis is usually conducted. Further, it is to be remembered that our knowledge of the products of such proteolytic action depends almost entirely upon data accumulated by artificial digestive experiments. In no other way can we be absolutely certain of the conditions under which the proteolysis is accomplished, for it is a significant fact, perhaps plainly evident from what has already been said in the preceding lecture, that the character of the products resulting from ordinary proteolysis is dependent in great part upon the attendant circumstances. Thus, with a relatively small amount of acid, and perhaps also of pepsin, the initial products of proteolysis are especially prominent, while with an abundance of both pepsin and free acid, coupled with long continued action, the final products predominate. Between these two extremes there are many possible variations, as was, I think, made clear in the previous lecture. At the same time, it is to be noticed that these differences are mainly differences in the proportion of the several products, rather than in the nature of the resultant bodies.

In a general way, the products of pepsin-proteolysis may be divided into three main groups, viz.: bodies precipitated by neutralization and represented mainly by the so called syntonin or acid-albumin; bodies precipitated by saturation of the neutralized fluid with ammonium sulphate and represented by proteoses; bodies non-precipitable by saturation with ammonium sulphate and represented by amphopeptones. The relationship of the individual products may be clearly seen from the follow-

ing scheme, arranged after the plan suggested by Neumeister.

It is, of course, to be understood that this is not intended to represent anything more than the order of formation of the several bodies, no attention being paid here to the hemi- or anti-character of the several products, or classes of products. Thus, proto and heteroproteose are primary bodies formed directly from the initial product syntonin by the further action of the ferment. In the same sense, deuteroproteose is a secondary proteose, being formed by the further hydration of the primary body. Lastly, peptones, the final products of pepsin-proteolysis, are the result of the hydration and possible cleavage of deuteroproteoses. Further, in almost every gastric digestion there is also formed a small amount of antialbumid, a product insoluble in dilute hydrochloric acid and which consequently appears as an insoluble residue. This body is very resistant to the action of pepsin-acid when once formed, but may be slowly converted, in part at least, into a soluble antialbumose and thence into antipeptone.

All of these bodies can be readily identified in any digestive mixture containing them by a few simple reactions. Thus, after having removed any acid-albumin or syntonin present by neutralization, the concentrated fluid can be tested at once. If primary proteoses are present, the neutral fluid will yield a more or less heavy precipitate on addition of crystals of rock-salt, precipitation being complete only when the fluid is saturated with the salt. Further, if the proteoses are present in not too small quantity, nitric acid added drop by drop to the neutralized fluid will produce a white precipitate, readily soluble on application of heat but reappearing as the solution cools. If primary proteoses are wholly wanting, then no precipitate will be obtained by acid unless the fluid is saturated with salt, in which case a portion of the deuteroproteose will be precipitated. The two primary proteoses differ from each other especially in solubility; protoproteose being readily soluble in water alone, while heteroproteose is soluble only in salt solutions, dilute acids, and alkalies. Hence, when these two bodies are precipitated together by saturation with salt, they may be readily separated by dissolving them in a little dilute salt solution and dialyzing the fluid in running water until the salt is entirely removed; heteroproteose will then be precipitated, while the proto-body remains in solution.

By long contact with water, and even with concentrated salt solutions, heteroproteose tends to undergo change into a semi-coagulated form, named dysproteose, insoluble in dilute sodium-chloride solutions. This body can be reconverted into heteroproteose, in part at least, by solution in dilute acid, or alkali, and reprecipitation by neutralization.

As a class the proteoses are characterized by far readier solubility in water than native proteids, by a far greater degree of diffusibility, by non-coagulability by heat and by alcohol, although precipitable by the latter agent. Further, nearly all proteose precipitates are exceedingly sensitive toward heat, tending to dissolve as the fluid is warmed and reappearing as the solution cools. In fact, this peculiarity often serves as a means of identification. Potassium ferrocyanide and acetic acid, picric acid in excess, and likewise cupric sulphate, all precipitate the primary proteoses, while deuteroproteose is only slightly affected by these reagents, or indeed not at all.

In order to separate the secondary proteose from the primary bodies in the absence of peptones, the fluid is neutralized as nearly as possible, and then, after suitable concentration, is saturated with sodium chloride for the partial precipitation of the primary proteoses. To the clear filtrate, acetic acid[1] is added drop by drop as long as a precipitate results, the latter being composed of a mixture of protoproteose and deuteroproteose. That is to say, protoproteoses are not completely precipitated from neutral solutions by saturation with salt alone; a little acid is required to complete it, but this tends to bring down a certain amount of deuteroproteose. From this filtrate, however, the deutero-body can be separated in a pure form by dialyzing away the salt and acid, and then concentrating the fluid and precipitating with alcohol. When the proteoses are mixed with peptones, the former must first be separated collectively by saturation of the fluid with ammonium sulphate. Peptones are especially characterized through non-precipitation by the ordinary precipitants for proteid bodies, and especially by the fact that they are wholly indifferent to saturation with ammonium sulphate either in neutral, acid, or alkaline fluid. This reaction, which constitutes the main, and perhaps the only absolute, method of separating peptones from proteoses must be carried out with great thoroughness in order to insure a complete precipitation of deuteroproteose. The latter stands midway between primary proteoses and peptones in many respects, and seems to share with peptones something of a tendency to resist precipitation by the ammonium salt. Indeed, as Kühne[2] has recently pointed out, the last traces of deuteroproteose can be precipitated from the fluid only by long-continued boiling of the ammonium sulphate-saturated fluid, and even then it is seldom complete unless the reaction of the fluid is alternately made neutral, acid, and alkaline, and the heating continued for some time after each change in reaction. Under such circumstances the last portions of deuteroproteose separate from the salt-saturated fluid and float on the surface in the form of an oily or gummy mass, while the true peptone remains in the fluid absolutely non precipitable by the salt.

In this filtrate, peptone can be detected by adding to a small portion of the fluid a very large excess of a strong solution of potassium hydroxide, followed by the addition of a few drops of a very dilute solution of cupric sulphate. If peptone is present, a bright red color will appear, the intensity of which, with the proper amount of cupric sulphate, will be proportional to the amount of peptone present. If it is desired to separate the peptone from the ammonium-sulphate-saturated fluid, there are several methods available, of which the following is perhaps the most satisfactory: The fluid is concentrated somewhat, and allowed to stand in a cool place for crystallization of a portion of the ammonium salt. The fluid is then mixed with about one-fifth its volume of alcohol, and allowed to stand for some time, when it separates into two layers—an upper one, rich in alcohol, and a lower one, rich in salts. The latter is again treated with alcohol, by which another separation of the same order is accomplished. Finally, the lighter alcoholic layers containing the peptone are united, and exposed to a low temperature until considerable of the contained salt crystallizes out. The fluid is then concentrated, and after addition of a little water is boiled with barium carbonate until the fluid is entirely freed from ammonium sulphate. Any excess of baryta in the filtrate is removed by cautious addition of dilute sulphuric acid, after which the concentrated fluid, reduced almost to a sirupy mass, is poured into absolute alcohol for precipitation of the peptone.

So separated, the peptone formed in gastric digestion is exceedingly gummy, but can be transformed into a yellowish powder, very hygroscopic, of more or less bitter taste, and, when thoroughly dry, dissolving in water

[1] Saturated with sodium chloride.

[2] Erfahrungen über Albumosen und Peptone. Zeitschr. f. Biol., Band 29, p. 2.

with a hissing sound and with considerable development of heat, like phosphoric anhydride.[1]

I have introduced these dry chemical facts, none of which are especially new, because I deem them of considerable importance and because they are not very generally known. In fact, there seems to be a tendency on the part of many who are more or less familiar with the advances made in our knowledge of the products of pepsin proteolysis to question the existence of these different bodies, or to show at least a spirit of indifference toward these recent facts which have been gradually accumulated, and I may say accumulated at the expense of considerable labor. The time is past for calling the products of gastric digestion peptones; it is time for a full recognition of the fact that pepsin-proteolysis is synonymous with the production of a row of bodies, chemically and physiologically distinct from each other, each endowed with individuality enough to admit of certain detection, and all bearing a certain specific and harmonious relationship to their neighbors, the other members of the series.

Further, it is not enough to admit the formation of a single intermediate body, midway between syntonin and peptone. The so-called propeptone of the past is simply a mixture of proteoses, of ever changing composition, varying with each change in the proportion of the component proteoses. Each of these proteoses can be detected, under suitable conditions, in the products of every artificial digestion as well as in the stomach contents, and no better measure of the proteolytic power of the natural stomach secretion can be devised than a study of the character of the individual bodies present in the stomach contents after a suitable test meal. The proper tests and separations can be made with a small amount of the filtered fluid, and much light thrown upon the digestive power of the secretion by even a rough estimate of the proportion of primary and secondary proteoses and peptones formed in a given time after the ingestion of a certain amount of proteid food.

In pepsin-proteolysis we have to deal, in my opinion, with a series of progressive hydrolytic changes in which peptones are the final products of the transformation. Commencing with the formation of acid-albumin or syntonin, hydrolysis and cleavage proceed hand in hand, under the guiding influence of the proteolytic enzyme, and each onward step in the process is marked by the appearance of a new body corresponding to the extent of the hydrolysis; each body, perhaps, being represented by a row or series of isomers, all externally alike, but differing in their inner structure, according to the proportion of hemi- and anti-groups contained in the molecule. As opposed to this theory, we have the older views of Maly,[2] Herth,[3] Henninger,[4] and others based upon observations which tend to show that peptones do not differ in chemical composition from the proteids which yield them. As a matter of fact, the products then analyzed were not peptones at all; they were merely the primary products of pepsin-proteolysis, *i.e.*, what we now term primary proteoses, and it is time we stopped using such data to enforce the theory that peptones are polymers of the proteids from which they are derived.

In 1886, the writer, in conjunction with Professor Kühne, commenced a study of the various cleavage products [5] formed by the action of pepsin-hydrochloric acid from the better characterized and purer proteids, this being a continuation of our earlier work on the proteoses and peptones formed from blood-fibrin, serum albumin, etc. This work I have continued in my laboratory up to the present time, with many co workers, and as a result we have to-day a series of observations gradually accumulated during these last seven years, some the results of work carried on this last year, which speak in no uncertain way of the character of both the primary and secondary products of pepsin-proteolysis. Furthermore, in attempting to settle this question once for all, I have selected for study examples from the various classes of both animal and vegetable proteids; and as representatives of the latter have had carried out two lengthy series of experiments on the crystallized proteids which occur so abundantly in some seeds, on the assumption that these crystalline bodies would furnish a certain guarantee of purity which might naturally be lacking in the amorphous proteids of animal origin. Some of these results are now placed together in the following tables, a study of which reveals some very interesting facts:

COMPOSITION OF PROTEOLYTIC PRODUCTS FORMED BY PEPSIN-HYDROCHLORIC ACID.

[1] Chittenden and Williams: Not heretofore published.

In considering these results, it is to be noticed that there is general unanimity of agreement except in the case of the albuminoid gelatin. In the proteolysis of this body, for some reason not explainable, the digestive products show no marked deviation from the composition of the mother proteid, but in every other instance there is to be traced a distinct tendency toward diminution in the content of carbon, proportional to the extent of proteolysis. In the primary bodies, proto and heteroproteoses, the percentage of carbon is only slightly lowered; indeed, in some few cases, notably in elastin and casein, the primary products show a slight increase in their content of carbon, but in most instances there is a slight falling off in the percentage of this element. In the deuteroproteoses, however, the loss of carbon is very marked. The percentage loss, to be sure, varies with the different proteids, doubtless dependent in part upon the nature of the proteid itself, and also, I think, upon the strength of the proteolytic agent employed and the duration of the proteolysis. It is to be further noticed that peptones, whenever analyzed, show a still further loss of carbon and also a marked loss of sulphur. In nitrogen there is no constant difference.

(To be continued.)

GREEK AS THE INTERNATIONAL LANGUAGE OF PHYSICIANS AND SCHOLARS IN GENERAL.[1]

By ACHILLES ROSE, M.D.,

NEW YORK.

All those who attend the International Medical Congresses notice an unpleasant circumstance, which becomes more and more marked with every succeeding assemblage. It is the inconvenience caused by the want of one language understood by all. There are some members who understand and fluently speak the official languages; they can easily take part in every debate, no matter which official language is used by the speakers. But few such members can be found; the majority of the participants, and among them frequently some who are most prominent in their specialties, understand but one language, and thus lose about two-thirds of everything spoken during the meeting. They are often unable to enter upon the discussion of a question because they cannot understand the subject mentioned; and if they speak on some subject, as a rule it is not understood by at least two-thirds of the participants in the congress.

An illustration of the difficulty thus presenting itself on account of the polyglot condition of these medical assemblies, is found in a letter written by a prominent German surgeon, dated December 28, 1892, to the President of the American Surgical Association, concerning the Pan-American Medical Congress.

The languages of the congress were the Spanish, French, Portuguese, and English. The German was excluded, probably because it is nowhere in America recognized as official.

The surgeon says in his letter: "I do not believe that the physicians of Germany will be able to take an active part in the transactions of this Pan-American Congress, unless they are enabled to use the German language in delivering their lectures."

The difficulty in this case was overcome by changing the statutes, by allowing lectures to be delivered in any language, provided that the authors of lectures in other than the official languages transmit to the general secretary a synopsis, of not more than six hundred words, before a certain date in advance of the date of the congress. A further condition was that a manuscript of each lecture of this kind was to be delivered, before or during the session, to the recording secretary of that section before which the essay was to be read. Remarks on articles read could be made in any language, provided the member making such remarks handed them in, before the close of the meeting, written in one of the official languages. I enumerate these details in order to illustrate how complicated the difficulties of a polyglot congress are. Everybody can complete this chapter either from personal experience or by meditation.

One might think the remedy in this dilemma would be the adoption of an universal language, and indeed, this idea has already for a long time occupied the minds of the greatest thinkers, above all, of Leibnitz. His attempt was based on the supposition that every act of thinking might successfully be reduced to an arithmetical

[1] Read before the New York Academy of Medicine, March 15, 1894.

basis, if it were possible to discover symbols for the most simple comprehensions and for the combination, as well, of such symbols, as, for instance, is done in mathematical science. Already in his youth he aimed at this purpose in a well-developed plan, maintained up to old age, of a "*Characteristica universalis*," or "*ars signum et lingua philosophica*." However, this plan was never realized. As far as his idea was correct, it has been carried out by the signs of the mathematical and chemical sciences. A world-language, so far, exists only in the telegraphic marine code.

As the attempts of Leibnitz failed in the seventeenth century, so also have failed those of the eighteenth century.

During the nineteenth century the means of communication increased in gigantic proportion, international commerce became of far more importance than ever before, and the attempts at creating a world language have been resumed. The best known of these is the Volapük of the Rev. Mr. Schleyer, and the partial success obtained for some time by this artificial language proves the existence of a great desire for an international means of communication.

Whatever may have been the object of Volapük, it could never have been the intention of the inventor, nor could it have been expected of him, to make it an international language for scientific purposes.

It was an idea of King Maximilian of Bavaria, to transmit to history a reminder of his reign. He instructed the architects of Germany to design a new style to be named after him. Such a style of Maximilianesque was created. I have seen, in Munich, houses built after this plan. An architect—it was Semper, if I be not mistaken—when asked to take a part in this creation of the so-called Maximilian's style, answered, that such a thing could not be made to order, that a style of building is the consequence of the history, the culture, life, and doings of a great period of a people. If such be the case with a style of architecture, how much more must it be the case in regard to language.

The history of this style of Maximilian's is, that it has no history. This short history is also that of the attempts to create a new world-language.

While an universal language, sufficient to satisfy the intellectual want of every people and of every time, can be as little imagined as the equality of all mankind, still such an uniformity is possible in a restricted part of human society, viz., in that aristocracy formed by art and science. It is not the masses who need such an universal language, but the men of science.

Since Latin is no more used as an international scientific language, the want of such a language makes itself more and more felt as science extends. I do not know if any, and what, serious attempts have been made in regard to this desideratum. I read that the American Philosophical Society has proposed that the question of the creation or adoption of an international scientific language should be considered at a congress which was to be held at Paris in connection with the last Exhibition. I read further that the Société de Médecine Pratique had taken up the question, and a commission, consisting of representatives of the principal scientific associations in Paris, had been appointed to study the matter. As far as I have learned, these associations set their face absolutely against Volapük.

Just at present there is much agitation in France for reform of instruction and examination in medicine. The Ministry of Instruction propounded quite recently questions in this direction, to be decided upon by the medical faculty of Paris. A commission of five professors and the rector of the faculty have considered these questions, the principal of which was whether the study of the classical languages should be abandoned. The commission in its answer said: The physician is obliged to use a terminology which is derived from the Greek and the Latin. Although he may, without having been instructed in the classics, in the course of time acquire a superficial knowledge of the expressions, still there will remain in such a case a sentiment of inferiority because he does not know their origin. In the interest of the dignity of the profession, this sentiment should be spared to the future physician. The commission further said it would be absolutely necessary that, in addition to the knowledge of the classical idioms, the knowledge of one of the modern languages should be required, namely the German. In the present condition of the medical science, which derives its elements from all parts of the world, every physician ought to be somewhat of a polyglot.

The rivalry of the nations is against the employment—as an international language—of one of those principally spoken in the civilized world, such as English, French, or German. In addition these languages are insufficient for the expression of new ideas and for the composition of words. Even as it is now, the English, French, and German scholars have one thing in common; they borrow from one and the same language when new words have to be formed for new things. They borrow from the Greek, from that language which has many claims to be preferred to every other in the selection of an universal language for scholars.

In choosing the Greek no mutual rivalry need be taken into consideration. It is the old, old idiom of a small nation and of a small country. The language is rich and is musical, clear, and precise, and especially abounding in combinations. It is able to render every modern idea completely, and already it has, in this regard, given life to thousands of words. In thousands of schools, and in every university, it forms a necessary part of instruction. Not only do we use a multitude of Greek words in our daily intercourse, but our entire medical terminology, also the general terminology of the arts and of sciences, is, for the most part, dominated by the Greek language.

The magnificent structures of the ancient Greeks, their equally splendid works of sculpture, have been so little approached by us, that nobody, in the whole world, would entertain the possibility of a comparison in our favor when modern achievements are contrasted with the masterpieces of Greek art. The Temple of the Olympian Jupiter, the Acropolis of Athens, the Venus of Melos, the Hermes of Praxiteles, are proofs that the Greeks had a much better developed sense of beauty than any other people of a later age.

Greek art is still alive, for it affords the highest examples for our architects and sculptors. Everybody knows this to be a fact.

The Greek language still lives, the same old Greek which is taught in our schools—taught, however, by the eye only. It is spoken by seven million people, and it is more beautiful and noble than any other language, just as Greek art is more beautiful and more noble than any other. There are, however, but few who seem to be aware of this fact.

Greek has once before now been the world's language. Its use was extended over a larger territory than the Latin. "*Græca leguntur in omnibus fere gentibus. Latina suis finibus*," says Cicero. "*La langue grecque deviendrait la langue universelle*," Voltaire wrote. The humanists at the end of the Middle Ages thus caused its Renaissance.

Let us hope that a second Renaissance and a brilliant period of the study of the Greek language will ensue, the final purpose of which can only be the greatest possible extension of genuine science and culture.

The colleges have sprung from the Latin schools of the Mediæval Age; they have, on this account, inherited a steady preference for that language. The general use of the Latin on the part of the learned profession, has, in the easiest manner, facilitated the learned intercourse of all. This has now, however, altogether changed. The national languages have obtained their natural rights, and should always maintain them, even if an universal or international language for scholars shall have

been adopted. We must concede that it is impossible to reinstate the old relation the Latin has held—when all the lectures on any subject whatever at the universities were delivered in Latin. Neither would such be desirable.

Virchow says, in his inaugural address as rector of the Berlin University: "It was from the beginning a weak side of humanistic educational institutions to favor the Latin language. It must be conceded that they could not do otherwise. They found the Latin the universal language of church and law. They were all Latin schools. They only continued what had become a general practice in consequence of the habit transmitted for a thousand years. But for this reason they had accepted an element of weakness. For the classical writers of Rome were in their works way behind the Greek authors. Indeed, the best among them are indebted to their Greek antecedents for their education. The school of Athens formed the background of all learned activity. Our own Western civilization has adopted from the Greek literature the really moving thoughts and the facile forms. Homer, Aristotle, and Plato have continued to be, up to our time, the teachers of mankind.

"Since the Greek authors have again been read in the original, the active interest in the Latin language has been reduced. Still, the Latin remained the principal object of information. But it steadily accomplished less. As the use of the language as such became gradually less, rhetoric was omitted, restricting the study more and more to the grammar. Indeed, instruction in grammar gradually so overpowered everything that even the Latin essay became a pium desiderium."

The Latin, as an international and scientific language, loses every day more of its importance. Indeed, it might almost be said that it is only kept alive in purely philological and theological literature. Latin is a dead and restricted language, insufficient for the present time.

The number of Latin scientific terms, with the exception of the vocabulary for law matters, is inferior to the number of words from the Greek. Moreover, we possess only the written Latin language; the language of daily commerce has not been transmitted. The Latin of the church, of the learned, is an artificial, a forced language. It can easily be understood why, under these circumstances, the instruction in Latin became more and more purely grammatical; but why the Greek, a living language, a language just as living as our own, has been treated alike in our schools, is a question which should be addressed to all the learned world, in order to expose a wrong that has been committed and kept up for centuries.

"Grammatical schooling," says Virchow, "is not that auxiliary means of progressive development which is needed by our youth. It does not cause that desire for learning which is a presupposition of independent further development; but, on the contrary, it is manifest that many scholars, as well as their parents, regard it with hatred."

Professor John Williams White, of Harvard College, says: "High grammar, philological research concerning forms and laws of construction, should be undertaken by no one until he is well on his course, and, it may well be, by the majority of men never at all. The study of the classics is an effective means of mental discipline, but theoretical grammar does not furnish the best field for its exercise."

Study, like almost everything else in our times, and especially in this our country, must be done at high pressure; and no time is to be lost, since many things have to be learned. It is true the Boston Latin School does not do what it did forty years ago—teach boys for a whole year the forms, rules, and exceptions of Latin grammar without even a single sentence of illustration; the "Method of Classical Study," by Dr. Taylor, of Andover, in which he asks seventy-six questions upon the first three lines of Xenophon's "Anabasis," and one hundred and twenty-seven upon the first three verses of "Æneid," I suppose is not in use any more; yet radical change of instruction in the classical languages, especially in Greek, is needed, whether we consider either of these languages as an international medium or simply as a means of mental discipline.

In order to command a language, it is above all necessary to know how the people speak. The every-day language must be familiar to us. Whoever knows the conversational language of a nation has the key to the understanding of its writings like the people themselves.

The Attic boy needed for reading the Greek poets, the Attic farmer for the theatre or a public meeting, only the knowledge of the Attic conversational language in its most simple form. It enabled them to understand the tragedies of Sophocles and the speeches of Pericles.

It has often been claimed that there are remarkably few words and sentences which suffice for the common man in speaking his native language, and which enable him to understand even that, which to him is a new formation. The every-day language must first be known before acquiring the art language.

Macaulay and others recommend, while learning a language, to lay aside the grammar, as the laws of speech will be easily comprehended while reading good authors. It seems to me that whosoever begins the study of a language with the learning of its rules, will never learn the language, unless he abandons the study of the grammar and commences anew.

So long as Greek is taught in the schools according to the present methods, it will be considered as a language too difficult to be learned, and could not be selected for an universal language.

Greek is a living language and must be treated as such. It is difficult to find a proper expression without using strong terms, to characterize the erroneous common opinion that Greek is a dead language!

We frequently meet with people who, having attained a certain degree of education, make this mistake, while as a matter of fact Greek newspapers are continually published, and new books, also, appear regularly in the Greek language treating of various subjects. An uneducated man may be excused for such mistakes, as certainly professional philologists have contributed not a little to the propagation of such views.

The professors of the classical languages simply pay no attention to the living Greek, without having even the least semblance of any grounds for such disregard; and yet they pronounce the language of the Muses according to the usage of their respective countries, in the English, Dutch, or German manner. The pronunciation, which ought to be alone the rule, is unknown to them, nor do they wish to know it.

Nothing is easier than the proof that the Greek is not a dead language. The daily Greek newspapers published at the present time prove that the Greek language of to-day is still the same Greek of the classical age, showing merely some differences as each living language undergoes in the course of time. Look, for instance, into the Ἡμέρα, published in Trieste. Whoever has been instructed merely at school, on beholding for the first time this paper, will be agreeably surprised to find that he is able to understand its contents without any difficulty. A better and more convincing proof can hardly be imagined.

The fact that the Greek language alone has preserved itself almost unchanged through thousands of years in its original beauty is, in my opinion, as a modern Greek writer expresses himself:

> "διότι τὸ ὡραῖον εἶναι ὡσὰν λάμψις τοῦ ἡλίου ἐπὶ τῆς γῆς, διότι τὸ ὡραῖον ζῇ αἰωνίως."

The Greek language has been transmitted together with its pronunciation. The majority of the Greek people, kept in bondage since the mediæval age until 1822, were altogether unable either to read or write.

Much has been said garrulously about the degenerated

descendants of Pericles, Socrates, and Phidias. Still, these degenerated descendants have the undeniable fortune to speak a language which Pericles, Socrates, and Phidias would have understood. An unbroken chain continues from generation to generation, and back again, from the Greeks of the nineteenth century to those of Pericles, Socrates, and Phidias.

The Greek language is immortal!

An interruption of Greek culture and of the use of the pure, fine, literary language, has never happened in Greece, not even after the Latin conquest in 1204 and the Turkish conquest in 1453. This tenacity of the Greek language has been accounted for by the fact of the beauty and the magnitude of its classical literature. A large tree, which excludes all sun-rays underneath its mighty foliage, will not permit other plants to be lighted and warmed and to thrive within its reach.

The Greeks always regarded their language as of wonderful beauty, and looked upon new elements which might have been introduced into it as vulgar corruptions. School, Church, Administration, Military, Legislature, Courts, Correspondents, Literati of all centuries, used the pure literary Greek, and never even the κοινή, the vulgar or people's language. Even the Roman reign, which forced many nations to adopt the Latin language, had no powers to interfere with the continuation of the use of the Greek. To emphasize it once more: The Attic, the classical language, with its forms, words, constructions, expressions, orthography, has always been regarded as sacred, as something which alone has a right of existence, which had to be preserved as free as possible from new elements.

When Greece had regained her liberty, after almost four centuries of Turkish bondage, a regular government was to be erected. Countless numbers of demands were made on the language. A new life, a culture of which there had been no idea before, appeared suddenly before the Greeks. The language had to keep pace with the many new political, scientific, technical, commercial, journalistic requirements. Another nation would certainly, under such circumstances, simply have adopted with the foreign ideas also the words of foreign people, and would have formed a half French and half hybrid language. Not so the Greeks. Their history has led them to exclude foreign words, led them to take the necessary elements from the old Greek to create new symbols for new ideas. This was a gigantic work. Stephanos Kumanudes has enumerated thirty thousand words which have been created during the last one hundred years. Let us illustrate how the work was done by a few examples: During the last century the foreign word σταμπαρία had been used for printing establishment—then τυπογραφεῖον had been formed, and from the latter a great number of combinations were made which could not possibly have been formed from σταμπαρία. In the same manner was said ἀβουκάτος, then the genuine Greek δικηγόρος, or first πόστα, then ταχυδρομεῖον, etc. These and thousands other foreign words are now entirely out of use and may be known only to the oldest people, the majority of the Greeks have no recollection of them.

It is a customary assertion that the modern Greek is a barbarous mixture of a good deal of Slavonic, Albanese, Turkish, and Italian, and of a little corrupt Greek. As we have seen, this is just as untrue as the assertion that the Greek is a defunct language. Naturally, such incorrect views are held among the ignorant. However, as I know from experience, such ignorance is found also among the otherwise educated classes who have studied the Greek language while at college. It is remarkable how the very Greek language, from which every other European language has drawn so freely, has been calumniated in such a manner.

Aside from the Greek as published in newspapers and books, which some are pleased to designate as an artificial old Greek in a new Greek garb, the living and really spoken language of both the higher and the lower classes, of the inhabitants of the cities as well as of the peasantry, is by no means a barbarian mixture, but rather a genuine Greek. Everybody acquainted with this language is aware of this fact. I cite as witness thereof: Ernst Curtius, a first-class expert in both forms of the Greek language, who says in his work "The New Greek and its Meaning with Regard to the Old Greek," that, excepting a few tracts at the border of the territory where Greek is spoken (as, for instance, the Ionian Isles), "even the lowest Greek uses a pure Greek language."

The question of the physical descent of the new Greeks, which cannot be separated from that of the language, is best settled by answering that of the descent of the language. According to late researches, a Slavonic descent of the Greeks can no longer be maintained. Proof can be furnished that not only are the modern Greeks not Slavonic, but also that no trace of a Slavonic influence can be found, with one exception to be mentioned presently.

A colleague, who had studied Greek and was also a college graduate, claimed, while conversing with me, that the modern Greek and Slavonic languages were very much intermingled. A Greek gentlemen, a scholar, on hearing this reproach, replied: "I shall be very much obliged to this gentleman if he will mention even one single Slavonic word found in the modern Greek language." The Slavonic is entirely restricted to the designations of habitations, hills, landscapes, waters, and even then it appears only in occasional places and by no means in all Greece.

In spite of a long-continued intercourse, the Albanese have, if possible, left still less traces in the Greek language.

It is somewhat different concerning the Turkish language. The Turkish dominion was for centuries very effective and oppressive, it cannot, therefore, seem strange if words of the official language have permeated the language of the conquered people. In the written language, however, nearly everything of foreign origin has been carefully avoided.

It is true the works of the modern Greek writer are not of as much beauty as the works of the classical period, but the language is not to be accused for this. The marble of Pentelicon is not at fault when, in later periods, no Venus of Melos, no Hermes of Praxiteles could be formed of it.

In comparing the new with the old Greek, the mistake is frequently made of considering as old Greek the written Greek of the Attic poets and writers of the classical period. The new Greek of the people's language is compared with a dialect of the old Greek written language. Unlike is compared with unlike, in order to prove that in the real living language the forms of the old Greek have been partially lost, partially changed.

The pronunciation, as taught in our schools, differs to an extraordinary degree from that of the language of the Greek nation of the present time. This school pronunciation lacks every scientific authority. The ignorance of the new Greek shown by most of those who take sides against the modern Greek pronunciation of the classic Greek language is astonishing. Philologists have written in favor of the school pronunciation and against the pronunciation of the living Greeks, although they have never heard real living Greek spoken by a Greek.

The Greek of the schools is looked upon as a dead language, the method of teaching as well as the purpose for which it is taught, are of no account for practical life. Those leaving school, except such as choose philology as a profession, forget what they have learned more rapidly than they have learned it, and thus it seems to be of no consequence to the teachers whether the Greek is pronounced in one way or another. A custom handed down for three hundred and sixty-five years is followed, and thus the necessity is removed of imparting to the language the sound of a living, undoubted Greek idiom.

The French, English, and Russian pedagogues think in the same manner as the German philologists, therefore the Greek language is learned in the respective countries

according to the modern high German, French, English, and Russian pronunciation, and forgotten again. The fate of the Greek language in the schools seems therefore to be sealed, unless a better mode of instruction is introduced. A language which is spoken by seven million people is forcibly reduced to a defunct language.

A school which is proud of its scientific teachers should teach nothing that has been proved, and been also admitted, to be unscientific and false. Neither should this be done even with a real defunct language. Nor does it ever happen in regard to any dead or living language, except in the case of the Greek. Instruction in the living languages is not given with an invented pronunciation, and even in teaching dead Latin and Hebrew a pronunciation is taught in the schools which is pre-eminently based upon the living tradition. Latin is taught as it is transmitted through its pronunciation in Italy, and through the pronunciation of the Italian language; Hebrew as it is really spoken by the Portuguese Jews.

Only with the Greek an exception is made by the school, and just in this case the existence of a living Greek language ought to be a reminder to place instruction in close relation to life, so that the scholar might later employ it for practical purposes. The phrase ought to be borne in mind: *Non scholæ, sed vitæ discimus.*

It is certainly very discouraging to the scholar who, having devoted years to the study of the language, finds that, thanks to the college pronunciation, he must pass among the Greeks in their beautiful country like a deaf and dumb person, neither understanding nor understood.

The time has passed long since when a creative activity in Attic philology and archæology was, almost exclusively, evinced in the dust of domestic libraries with fac-simile and picture book. The number of archæologists, especially since Schlieman, who try to enlarge the knowledge of old Greece in the new Greece is steadily increasing. There are inducements enough, even without the idea of making Greek an international language, to employ the pronunciation of the now living Greeks. No probability exists that the ancient Greeks spoke like the college professors; certain is it, however, that their pronunciation was similar to that of the Greeks of to-day.

The pronunciation of the colleges is an invention of Desiderius Erasmus, of Rotterdam. He has described the invention in his book "*De recta latini graecique sermonis pronunciatione dialogus.*" The book was published in 1528.

Which pronunciation had prevailed in Europe up to the invention of Erasmus of Rotterdam? The Greek, the same in all European countries, learned from the Greeks. After the conquest of Constantinople, Greek scholars fled to the Western European countries, and there gave lessons in the language of their ancestors, pupils did not doubt that the pronunciation of these modern Greeks had a historical right. Reuchlin, the great German philologist of the time of the Renaissance, has learned and taught the Greek language with the pronunciation of his Greek contemporaries, hence all persons who follow his example are called Reuchlinians. The modern Greek pronunciation, although not invented by Reuchlin, is called, curiously, Reuchlin's method in opposition to the method invented by Erasmus.

Erasmus has always spoken the Reuchlinian, but never in his life according to the method called after him. He also taught his students the pronunciation according to Reuchlin's method. Indeed, he had requested his Grecian friend Laskaris to furnish him a Greek teacher, in order that his own children should learn the correct pronunciation with their own ears and mouths.

The above-mentioned dialogue, *de recta pronunciatione*, is indebted, according to a well authenticated tradition, to the following farce: Erasmus, who was childishly vain about his Latin and Greek knowledge, and who styles himself "the most amiable prince of science," met with the following mishap: A gay visitor from Paris, inclined to perpetrate all kinds of roguery, told him the following fib: He had made the acquaintance of Greeks, very erudite men, who spoke in a manner entirely different from that in which all the world pronounced the Greek. And then he showed Erasmus how these remarkable Greeks spoke: exactly as if Greek was Dutch.

Whether Erasmus put full or only partial faith in this venture, it is certain he wanted to use it in order to aid his vanity; he intended to pose before the learned world as the inventor of this latest sagacity. The dialogue was composed in the year 1528. Most of the contestants in the battle about the Greek pronunciation have not even read this manifesto. It assumes the shape of a dialogue between a bear and a lion, is exceedingly tedious, a feeble and attenuated walz in trivial Latin.

The bear imparted to the lion that the old Greeks might have possessed the Dutch pronunciation interspersed here and there with specimens of the French expression. This nonsense spread like a prairie fire. A flood of pamphlets, agreeing with this dialogue, was the result.

The invention of the pronunciation, according to Erasmus, happened in no other manner. The professors of Greek need not boast of the history of their pronunciation of the Greek language; it shows anything but a scientific basis. If anyone doubts the truth of this, let him read the document of the dialogue referred to; it can still be obtained. It is hardly necessary to marvel at this story. The dialogue was published at a time when, in spite of profound erudition, there was hardly an inkling of the internal substance of a language, or even of the true relation of the languages to each other, to be found in the world of learning; at a time when the greatest imaginable nonsense was uttered in an erudite manner. Specimens thereof are the Latin essays, comprising large volumes, concerning the question whether Adam was created with a navel. At a large waste of learnedness it was also proven at that period: Adam and Eve, before biting into the apple in Paradise, must have spoken Dutch, but after the fall, the French language.

Since the sixteenth century a Babylonian perplexity prevails concerning the Greek pronunciation. Nobody understands the Greek of a foreigner, still less that of a Greek.

It is certainly remarkable that the perfectly arbitrary, senseless invention of a cranky pedant has remained in force since 1528. Every attempt to justify it, composing since 1528 a bulky literature, is based upon sophistry.

The followers of Erasmus have taken pains, up to the present day, to invent the scientific proofs for the correctness of their pronunciation.

In the course of time the pronunciation of every language changes in correspondence to the changes of the language itself. This we can perceive in an instance quite near us: The Canadian Frenchmen, having remained in an isolated condition, speak the French language to-day in exactly the same manner as it was written and spoken in France a century ago. Dialects undergo the least changes, as may be seen by comparing the writings of Zwingli, which are written in the very genuine Zurich dialect as it is spoken to-day. Examining the Manesian manuscript, containing the songs of Zurich poets of the thirteenth century, we find the same language which the people of Zurich speak to-day in their own dialect.

The application of these examples to Greek is near on hand: It is not probable that the pronunciation changed more during the same space of time than the language itself. The classic Greek was a well-sounding language, we know this through the Greeks themselves, as well as through the Romans. The Greek of to-day still belongs to the most melodious languages, its pronunciation gives a beautiful and pure harmony.

When we consider the absurdity of the school pronunciation of the Greek, we must regret that a clumsy joke perpetrated upon Erasmus, of Rotterdam—a joke which certainly does not become science on account of its venerable age—is still taken seriously by many.

I said above: "In order to command a language, it is above all necessary to know how the people speak. The every-day language must be familiar to us."

"Whoever knows the conversational language of a nation has the key to the understanding of its writings like the people themselves."

"The every-day language must first be known before acquiring the art language."

Should we not feel sorry for the student who begins learning English by studying the poetical works of Chaucer? In what a roundabout way would he finally be enabled to understand the peculiarity of the language of Longfellow; how long would it be before he would be able to derive any sort of enjoyment from this poet's writings, if he were to learn the English language by reading Longfellow's works exclusively, and in learning it were obliged to parse every word?

The color of a language and the kind of style of a literary work, can only be fully perceived by one who is able to judge how far this language differs from commonplace daily conversation. We do not subject good wine to a chemical analysis by means of acids and salts in order to prove its value, neither do we grammatically analyze a poem to enjoy its charm.

In learning a language we notice one thing: in order to advance rapidly we have to read, in the beginning, only such books as are written in an easily comprehensible style, the contents to be also of an entertaining character. If we choose the more difficult, serious, or tedious books, we shall not advance, but rather retrograde. If we begin with children's stories or literature for the common every-day people, we shall be surprised to find how soon we can dispense with the use of a dictionary. We soon guess and learn new words by reading the context. We thus learn to think in the language, and the more we progress the more we enjoy the better, the higher, the more serious, the classical literature.

Professor John Williams White, of Harvard College, in a series of articles published in the *New England Journal of Education*, in 1878, entitled "Latin and Greek at Sight," recommends the instruction in the classical languages after the manner of teaching German and French, *i.e.*, to accustom the pupils to read at sight, without any preceding preparation. He mentions that the pupils learn much more quickly and better to read the German than the Latin languages, although twice as much time is spent in the study of the latter. Concerning Greek, he says: "It is to be reckoned that it is more difficult to learn to read Greek than, for instance, German; but then there is not so much difference between the two languages as to justify the fact that pupils, after studying Greek for years, are not yet able to read without the aid of a dictionary, or through some other means of assistance, while they learn in a much shorter time to read German fluently."

In order to obviate this evil, he recommends, among other means, that the pupils should study no higher Greek or Latin grammar until they are enabled to read these languages with a certain ease, and also have read a good deal. His claims are rather modest. He says: "The study of grammar should be rendered more practical, especially during the first years. The pupil, after having studied both the Greek and Latin languages for three or four years, should be able to read the Greek writings of Xenophon, Lysias, and Herodotus, and the Latin of Cæsar and Cicero, without either previous preparation or the use of a dictionary.

Professor White, in his suggestions regarding reformation of the instruction in Greek, has not gone far enough, because he, like other college professors, ignores modern Greek. The literary Greek of to-day is identical with the Attic dialect in orthography, almost also in form; the syntax is here and there circumscribed and simplified. There is more difference between the Greek of Herodotus and the Greek of Xenophon, than there is between the Greek of the latter and the Greek of to-day. There is more difference between the English of Chaucer and the English of to day, than there is between old and new Greek. The living, the Greek as it is spoken and written in Greece to day, is the one which should be taught in our schools. The Greek, as it is taught in general in our schools, is simply a skeleton without life. Our college professors should not look upon Greek as a dead language, and above all they should give up pronouncing it in their barbarous arbitrary manner.

It appears to me that Greek, taught like other living languages, by one or the other modern methods—Meisterschaft's, or any similar system—is not more difficult to learn than French or Spanish, certainly much easier than German.

If we commence with a regular A B C book, a First Reader, Fairy Tales, then read works of the best modern writers—like Bikéla, we shall soon get the aim to acquire understanding, and highest pleasure in reading the old Greek classical authors, much better, and without having to undergo the well-known tortures of the present school instruction. If the acquiring of the Greek language is thus made easier, and the classical Greek literature more and more within our reach, Kant's saying will become more obvious. "Even during the dark ages great men have existed. During those periods, however, only those could attain greatness who, by nature, had been stamped for it. Now, since instruction has been perfected, men are made great by training."

If the Greek language becomes the property of all scholars of all civilized nations in such manner that it may serve as the medium of intercourse, there is no telling how great the practical advantage will be along with the ideal gain. The introduction of the living Greek language into our schools would be of not less significance than the work of the humanists at the end of the Middle Ages.

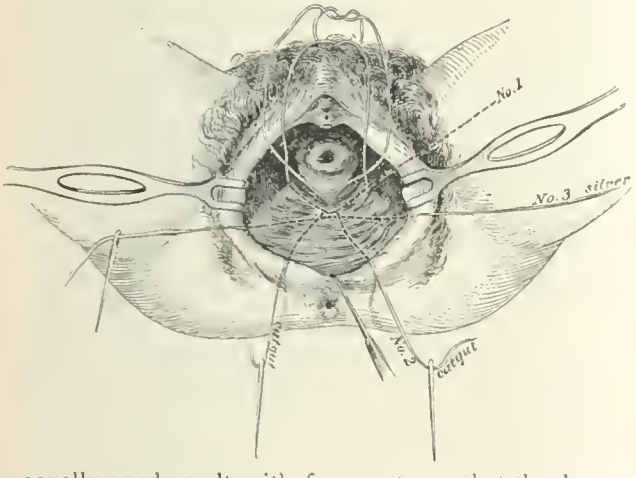
As the humanists in their times fought against the obstinate and clumsy form in which the scholastic science was taught, as they fought against the prevailing professional quarrelling, and the cunning and subtilizing in words, just as much is it timely now to oppose the unreasonable grammatical instruction in Greek in our schools. These men were inspired for the grand inheritance left by the ancient classical nations, they recognized in this inheritance one of the most excellent means of improvement of the mind, and an inexhaustible soil of noble sentiment.

The single individual can accomplish very little to have justice done to a language which our profession uses already so much in its terminology in preference to any other; to have this language seriously considered when the question of an international language for scholars of all nations is brought up; a language which gives terms to all new inventions and discoveries, and which cannot be replaced by any other; which is already, to a certain extent, an international language.

A NEW AND SHORT METHOD OF CLOSING THE PERINEUM.[1]

By PAUL OUTERBRIDGE, M.D.,

ATTENDING GYNECOLOGIST AT NEW YORK CANCER HOSPITAL; ASSISTANT SURGEON WOMAN'S HOSPITAL; ATTENDING PHYSICIAN AT NEW YORK LYING-IN ASYLUM; ATTENDING GYNECOLOGIST AT DEMILT DISPENSARY; MEMBER OF NEW YORK OBSTETRICAL SOCIETY, AND HOSPITAL GRADUATES' SOCIETY, ETC.



I TAKE up this subject with some hesitation, as it is one that has attracted universal attention on the literary as well as practical side, and am in hopes to throw a little light on this old but interesting subject.

In all probability Fricke was the originator of the operation, and his method was indeed primitive, consisting of a narrow denudation on either side of the labia which, when sutured, simply made a true bridge at the vaginal entrance incapable of giving any appreciable support to a rectocele. It served, however, to stimulate Simon, who quickly followed with the idea that the denudation should be continued up the introitus, which was a step in the right direction. This operation soon gained an extensive following, and a series of improvements in conse-

[1] Read before Hospital Graduates' Society.

quence was the result, both in the denudation and method of suturing. The most valuable addition of all has lately been advanced by Dr. Emmet, and if his method is followed a successful result will follow. I mean to say that after the operation the parts will resume their normal appearance. I shall not attempt todescribe the operation as done by him, but will infer that the gentlemen present are familiar with it and all the others.

If this method (Emmet's) is to be followed in doing the operation there are several things to be considered: 1, The method of passing the sutures would prove exceedingly difficult to one not in constant practice; 2, the number to be used; 3, the long time it takes to apply them, and lastly, the sutures are liable, if not exactly adjusted, to cause trouble, first, because there are a large number, and some are liable to be made a little too tight, while others are perhaps too slack; this, in itself, might cause failure. The time of doing this operation varies from one-half to three-quarters of an hour, and often even longer. Further than this, it really requires experience to make this operation a success. The exact adjustment of a long row of sutures is a problem also that needs the hands and head of an expert to solve. The time of operation, if long, must necessarily exert a bad influence on the anæsthetized patient, for in nine cases out of ten the woman is very much reduced as the result of the laceration, having, perhaps, a feeble heart action or slight trace of albumin in the urine. But under any circumstances we all know it is a decided advantage for a patient to be under the effect of an anæsthetic as short a time as possible. Considering this, I thought if the method of suturing could be simplified and shortened, so as to obtain an

equally good result with fewer sutures, that the dangers from sloughing in the hands of the general operator as well as of an adept would be much diminished, and the ill effects of prolonged anæsthetization prevented.

To accomplish this the patient is put on the back with knees flexed and held in this position by a Clover crutch, and the usual denudation made as shown in accompanying cut. Three sutures only are required to coapt these denuded surfaces, and I shall endeavor to make this clear by the aid of the cut and following description.

For the upper suture, or the one nearest the cervix, a medium-sized catgut is required about ten inches or a foot long, with a cervix (common needle) at either end. This will not only answer for the upper suture, but, as I shall later state, will also give the lower suture without the use of more catgut or a change of needles. Everything in readiness, one needle should be imbedded in the "crest," or undenuded tongue which is in the centre of the vagina, and continued along the upper line of denudation, coming out at the right upper angle in the undenuded tissue. The other should be continued in a similar manner to the left, coming out at the left upper angle. This catgut suture should not be ligated, but the needles on either end of it thrown over the symphysis—to have them out of the way. The next suture should be of silver, and the needle imbedded one-quarter inch above the denuded tissue, midway between the upper and lower points of denudation, or in other words, at the highest point of the denudation on the left side of labia, and passed from left to right, coming out in the corresponding place on opposite side, care being taken to have this imbedded from side to side. An inspection of the diagram will make this description a little more lucid and I trust convey the idea. At this stage the wire suture is left *in situ* with a clamp at either end, and the upper or catgut suture should be ligated, care being first taken to approximate the central point or tongue and the right and left angles. In order to do this it is often necessary to depress the central part with a tenaculum or its handle. After this is thoroughly secured, pass one of the needles on the end of the catgut in this now central point, downward and outward under the denuded tissue, bringing it out on one side of the labia about one-half inch above the lower point or angle of denudation; the other needle should be passed in a similar manner on the corresponding side; the diagram shows this distinctly. This last catgut or lower suture should now be tied, care being taken to draw this tightly. This closes completely the lower angle of denudation. The silver (or middle) suture is next to be twisted, which brings the two sides together, and should make the whole perfectly firm, and every part should be in perfect apposition. Occasionally a superficial suture is required when the sutures are not in proper position. I claim for this method of suturing, 1st, that it lifts the posterior wall up to the anterior, and makes a very firm and normal perineum; 2d, that it consumes very little time, and so lessens largely the dangers of anæsthesia—the operation by this method can easily be done in from six to fifteen minutes, depending on the dexterity of the operator; 3d, infinitely less irritation on account of the limited number of sutures; 4th, that it is almost impossible for any sloughing to occur—that it takes up all redundant tissue; 5th, that one suture only has to be removed; the other—or catgut—sutures are absorbed. This operation requires very few instruments, and certainly the expense of sutures and needles is very trivial. Three common cervix needles are required, one piece of medium-sized catgut about ten inches long, and one silver suture, six inches, one shot. Instruments required are three tenacula, one pair universal scissors, sharp-pointed (curved on flat), one needle forceps (three needles), one wire forceps and scissors. This constitutes the required outfit. The patients after this operation have little or no pain, and should not have the slightest rise of temperature. Bowels moved third day. Preparatory treatment consists simply of purgation two days before operation. Examine urine.

I have already performed over one hundred and fifty perineum operations in this manner, without a single failure. I have also used the same method in closing complete lacerations (lacerations through sphincter), taking the precaution, however, to first approximate the two edges of the gut either with a continuous or interrupted catgut suture, which closes or shuts off the rectum from vagina. I then proceed as before with the three sutures, and in two instances I have put an extra catgut suture through either end of the sphincter muscle to be certain to approximate the severed ends. I have already operated on five cases of this kind (laceration through sphincter) by this method without failure. And in one instance (a very poor woman), in which the laceration was a bad one, the patient got up on the fourth day, and did all the housework (going up and down stairs), and continued to do it until the end of the week, when the silver suture was removed, the result being perfect. In this instance the bowels were moved on the second day and every day after, Epsom salts being used for this purpose. In every instance in which I have done this operation for laceration through sphincter I have taken the precaution to thoroughly stretch the sphincter ani muscle before suturing, which I think a great factor to success, by whatever method closed. Finally, having had this extended success I feel that there are many advantages to be derived

from using this method of closure of the perineum, and if it be intelligently carried out success will, in my opinion, invariably follow.

AN UNUSUAL CASE OF EXTRACTION OF THE CRYSTALLINE LENSES.

By JOHN E. WEEKS, M.D.,

SURGEON, OPHTHALMIC DEPARTMENT, NEW YORK EYE AND EAR INFIRMARY.

J. T——, aged seventeen, was brought to me on October 18, 1892, on account of defective vision. The parents are healthy, robust people, giving no history of constitutional taint. The mother has given birth to six living and two dead children; the still-births preceded the birth of J. T——. All the living children were healthy. At the age of nine years the patient's eyes became inflamed. Ophthalmic surgeons in this and other countries were consulted, and their advice and treatment carefully carried out; however, the inflammatory trouble continued and did not subside until the patient reached the age of fourteen or fifteen years. Since that time the eyes have been comparatively quiet; however, the patient says that the acuteness of vision varies, indicating periodical disturbances. These periods are accompanied with a dull headache, which is not severe—sometimes scarcely perceptible.

A confrère, who had had the patient under treatment, kindly offered me the following data: J. T——'s eyes became sore in July, 1885. Was first seen December 15, 1885, when a diagnosis of interstitial keratitis was made. The cervical glands were enlarged; mercuric bichloride, gr. $\frac{1}{64}$ t.i.d., was given. April 6, 1886, R. E. V. $= \frac{20}{200}$, L. E. V. $= \frac{20}{40}$. The vision gradually diminished, until in October, 1886, it equalled, in the right eye, $\frac{20}{200}$; left eye, $\frac{20}{200}$ +. The iodide of potash and the biniodide of mercury were then being given.

During the period of inflammation of the eyes the hearing became impaired without acute inflammation of the ears. Their present condition is as follows: Membranæ tympani nearly normal. Vault of pharynx of normal size, and almost entirely free from any thickening of mucous membrane. No catarrhal inflammation of consequence. Hearing, right ear, loud voice at eight inches, bone conduction almost entirely abolished; by air-conduction a low C tuning-fork, violently vibrated, could be heard for twenty seconds. Left ear, loud voice at six inches, bone conduction abolished, air conduction, fifteen seconds. The diagnosis of labyrinthian disease was made, which diagnosis was subsequently confirmed by Dr. Albert H. Buck.

The condition of the eyes was as follows: R. E. V. $= \frac{9}{200}$, L. E. V. = counting fingers at six inches. Both eyes presented the picture of uveitis anterior. The corneæ were large and uniformly bulging, presenting here and there slight irregular opacifications. Some irregular astigmatism existed. The sclerotic, for about 5 mm. back from the sclero-corneal junction, was thin, permitting the pigment of the inner coats to show through. There was total posterior synechia in the left eye. The pupil was occluded by a pseudo membrane of long standing, which presented a small defect at its inner margin permitting of the vision above mentioned. In the right eye the posterior synechia was total, except at the nasal side, where a very small portion of the pupillary margin of the iris remained free. There was but little evidence of a pupillary pseudo-membrane in the right eye. Quite numerous isolated opacities were present in the lens, and remnants of a not very dense cyclitic membrane could be seen, lying on the capsule of the lens near its equator. On account of the presence of the pupillary membrane, the condition of the lens of the left eye could not be determined. The anterior chambers were deep. The irides were atrophic to quite a marked degree. The middle zone of the iris of the left eye was bulged forward, producing a typical, but not very pronounced "crater" pupil. The tension was above the normal in both eyes, that of the left being + T1, of the right, + T½. Projection good except at the periphery of the fields. The history of periodical diminution in the vision led me to infer that at times the intra-ocular tension was increased, and that temporary pressure amblyopia resulted.

Operation on the left eye was advised, contemplating iridectomy, the removal of the pupillary membrane, and the extraction of the crystalline lens. The operation was performed on October 22, 1892, under ether anæsthesia. An incision upward, including about one-fourth of the circumference of the cornea, was made at the limbus conjunctivæ. The iris was seized at the pupillary margin, carefully withdrawn, and a portion excised. The iris was thin and fragile, and tore slightly at the angles of the wound; some shreds were subsequently removed from these points. The point of a sharp Gräfe cystitome was passed around the margin of the pupil, causing partial detachment of the pupillary membrane, which was then seized with the capsule forceps and removed. The fixation forceps were then removed, when the eye rotated upward beneath the upper lid, making it extremely difficult to express the lens. The speculum was removed and a broad Desmarres's lid retractor substituted to raise the upper lid. By pressure with the spoon a small, semi-transparent, entire lens was expressed. A bead of vitreous now presented. After replacing the iris at the angles of the wound, the bead of vitreous was excised, the lips of the wound adjusted, and the eye bandaged.

The rolling upward of the eye after the fixation forceps were removed, was extremely unpleasant, the speculum became useless, and in fact dangerous, and some such instrument as Desmarres's retractor was indispensable to the completion of the operation. If ether had not been given, this unpleasant incident would not have occurred; it was given because the patient could not be depended upon to remain quiet during the critical steps of the operation. Its use rendered assistance from the patient impossible. The tendency to rotate the eye upward, inordinately developed during the long period of corneal inflammation, was much greater than is met with in uncomplicated cases; I determined to take the chances with an unruly patient under cocaine anæsthesia, rather than to give ether in other operations in this case. The healing process was uneventful.

Two weeks after the operation vision with correcting glass $= \frac{12}{200}$. The posterior capsule was much thicker than in uncomplicated cases, because of the peculiar mummified condition of the lens and the previous cyclitis.

Discission five weeks after the first operation. A large central opening was obtained by a crucial incision made with a scalpel needle (Knapp's).

January 3, 1893.—Vision L. E., with correction $= \frac{20}{40}$. Patient reads J. 4 quite readily.

On January 7, 1893, the same form of operation was performed on the right eye under cocaine, ten per cent. The patient gave no trouble and not the slightest accident occurred. A small, partly transparent, entire lens was expelled. Recovery uneventful.

February 2d.—R. E. V. $= \frac{16}{200}$ with correction.

February 11th.—Discission of the capsule. Quite a dense band representing the thickened free edge of the anterior capsule, traversed the keyhole pupil in a diagonal direction, just above the centre of the pupillary space. A canted T-shaped incision was made, the top of the T passing along the lower border of the dense band. A fairly large clear space was obtained, however; the aqueous escaped along the shaft of the needle, rendering it impossible to complete the division of the capsule. The opening in the cornea was closed with the actual cautery point and the anterior chamber was restored in a few minutes. Recovery uneventful.

On March 10th, a supplementary operation for division of the capsule was done, the opening obtained by the first discission proving to be too small. The anterior chamber was again emptied, however, the discission was successfully performed. Recovery uneventful.

The escape of aqueous in the two operations for discission in this eye was due, in my opinion, to extreme

thinness of the cornea. The same knife was used to perform similar operations on other eye, without the slightest escape of aqueous.

To day the vision of the left eye is $\frac{20}{10}$; of the right eye, $\frac{20}{20}$. The patient reads J. 1 at ten inches with ease. The thinness of the cornea and sclerotic, the atrophy of the iris, and the mummified condition of the lens, all bear evidence of the severity of the previous inflammatory condition, which is so commonly associated with hereditary specific disease. Lens fibres apparently ceased developing shortly after the inflammatory attack began, the shrunken condition of the lenses indicates a marked interference with their nutrition. No evidence of disease in the posterior two-thirds of the globe is present. The iodide of potash and biniodide of mercury were taken for six months, beginning at the time of the first operation. The patient is in excellent health. He uses his eyes constantly without discomfort. The vision is as good as can be obtained in the presence of the corneal opacities.

Clinical Department.

UNUSUAL CASE OF GUNSHOT WOUND OF THE BRAIN.

By J. E. TEFFT, M.D.,

SPRINGFIELD, MO.

There are to be found in surgical records, many cases of perforating gunshot wounds of the cranium that recovered. There are numerous cases of penetrating wounds, with recovery following, after extraction of the balls from the orifices of entrance.

There are many cases where the balls were not extracted, and the patients made recoveries more or less complete.

Cases, however, of penetrating gunshot wounds in which the balls were extracted from the opposite side of the head during the life of the patient, are certainly very rare; and such cases terminating in the recovery of the patients are still more rare.

Such being the state of the facts, the following case, though not terminating in recovery, is, I think, of sufficient importance to justify me in offering a report of it to the profession.

E. D——, a healthy boy, twelve years of age, was shot on July 4, 1893, with a pistol ball, calibre twenty-two, at short range. I saw him half an hour after the shooting. He had bled freely, was suffering considerably from shock, and was unconscious. Measures were taken for the relief of the shock, and he was subjected to operation two and a half hours after the receipt of the injury. The ball had penetrated the frontal bone, seven-eighths of an inch above the upper margin of the left orbit, and one inch from the middle line. No probing was done, but a flap was raised, and a button of bone and the splinters removed. It appearing that the ball had ranged backward, the head was placed in such a position that the apparent track of the ball was perpendicular, and a porcelain-tipped (Nélaton) probe introduced. This dropped by its own weight entirely through the inter-cranial mass, in direction backward and slightly downward, a distance of about seven inches, or seven and a half, when the inner surface of the cranium in the left occipital region arrested its further progress. Such a condition not having been looked for, only the front half of the scalp had been shaved. It then became necessary to shave and sterilize the remainder, which considerably protracted the operation. This having been done, an opening with a three-quarter inch trephine was made in the left occipital region, at the point indicated by the direction of the probe. On removing the disk of bone, the dark appearance of the dura showed that the right point had been reached. On incising the dura some partially coagulated blood escaped, and the tip of the probe was found at the upper margin of the opening. The ball not being apparent, another disk of bone was removed below the first, making a perpendicular opening, one and a half inch by three-fourths of an inch. This gave a better opportunity for search. The dura was not further incised.

After careful search the ball was found below the point where it struck the occipital bone, about one and a half inches, and embedded in the brain half or three-fourths of an inch. The ball weighs twenty-three grains. The wounds were carefully cleansed, and it was found that there was no hemorrhage nor oozing anywhere. Provision was made for draining the two extremities of the wound, but no tube was carried through the track of the ball, and the usual antiseptic dressings were applied. Though the change of base during the operation somewhat disturbed our antiseptic precautions, the wound remained free from pus throughout the treatment.

For the first three days there was a decided febrile condition, which subsided on the fourth day. The pulse and temperature then remained normal until the eighth day. The boy was conscious, intelligent; he ate, drank, talked, recognized his friends, and took an interest in his surroundings.

The special senses were unaffected, so far as could be ascertained. His articulation was fairly good, though some defects were noticed. The right leg was the weaker, though he kicked around with it. The right arm was much weakened, and he was inclined to keep the forearm flexed somewhat, though it could be straightened without disturbing him. On the eighth day he showed restlessness alternating with somnolence, his temperature rose, his pulse became more frequent, the pupils dilated, and he ceased to take notice of things. This condition gradually became more and more intensified, and he died comatose, on July 16th, twelve days from the date of the injury.

An examination was made, post-mortem, limited to an examination of the track of the ball, and the parts surrounding the two extremities of it. There was a very small fungus cerebri at each extremity of the wound. The track of the ball was not so far or so firmly closed, but that a tipped probe readily followed it. No abscess nor free pus could be discovered anywhere in the track of the ball or adjacent to either opening.

The question of drainage after cerebral operations is an important one. We are advised by some eminent authorities to use, in cases similar to the one above reported, a rubber tube extending entirely through, though it does not appear that they have used it, but that on general principles they think it advisable. In Dr. Fluhrer's celebrated case it was used, and allowed to remain three days. In my case there was no bleeding nor oozing. The wound, when the patient lay on his back, was nearly perpendicular. The natural drainage was certainly good.

Provision was made for draining the extremities of the wound, but as to the main track of the ball, I thought best to allow the opposing sides to fall together. Whether or not it was wise, readers will judge for themselves. I am very doubtful about it, though I saw nothing in the progress of the case, or after death, tending to show that further provision for drainage would have done good. Certainly in cerebral abscess, or in any brain wound which does not have complete natural drainage, or when there is hemorrhage, or serous oozing, or where there is likely to be pus, the best possible artificial drainage is imperatively demanded. The object gained, or sought, from drainage by a tube, is, I suppose, the giving to effused fluids a chance to easily escape.

When there is no effusion, and there is to be none, the tube is evidently not needed. When effusion has ceased, it is then time to remove the tube, and to allow opposing surfaces to fall together.

In this case there seemed to be no bleeding nor oozing, and I did not anticipate pus. Hence I did not use through drainage, but allowed the opposing surfaces to fall together at once.

SYPHILIS IN WOMEN.

IN Byron Bramwell's "Atlas of Clinical Medicine," Volume II., Part II., there is a very interesting exposition of syphilis and its results. Its manifestations in women present at times peculiarities that cause the true nature to be overlooked. The poison first produces a local sore and a local glandular enlargement, followed by a generalized infection of the blood, and probably of all the tissues. The only exception to this is the contamination of the mother through the fœtus. Of this particular mode of infection, Bäumler states that the syphilitic poison evinces a very peculiar modification of its action when it operates through the fœtus, procreated by a father affected with latent syphilis, upon the pregnant mother. Women that go through a number of such pregnancies begin gradually to suffer an impairment of health, without ever being infected in the ordinary way. A modified infection ensues which lacks the primary local affection, together with the stages of eruptions and condylomata Gradually increasing pallor and emaciation, alopecia, glandular enlargements, isolated bony nodes, gummata of the cellular tissue, or ulcers of the mucous membranes, or psoriasis palmaris, are the sole syphilitic manifestations that these women present. Zeissel states that such women complain of profuse menstruation, or abort when they become pregnant. Ricord, Diday, Depaul, as well as Hutchinson, claim that the contamination of the maternal organism, termed by the French *choc en retour*, is the result of a reabsorption of syphilitic embryonic fluids, the embryo owing its disease to the father. This manner of becoming infected must not be confounded with that described by Von Bärensprung, viz., that which takes place through the semen, with coincident conception. The latter is the same as any ordinary infection, and Von Bärensprung states that in these cases manifestations of syphilis generally occur in the tenth week of gestation.

Authorities differ as to stages of the disease in which a man may infect a woman with syphilis. During the primary stage the disease is entirely local. The blood and tissues are not as yet contaminated, and the disease can only be propagated by infection from the primary sore. In the secondary stage, the blood and tissues generally have become infected. The poison is now contained in the blood. During the earlier part of the secondary stage, at all events, the blood, the secretions from the secondary lesions in the mouth, on the genitals, etc., and the semen are all highly contagious. Whether this contagion lasts throughout the whole period of secondary symptoms, Bramwell considers doubtful. When the secondary stage is of long duration, it is not improbable that the blood and secretions lose their power of infection. So far as is known, the blood and secretions from the lesions of the tertiary period are incapable of propagating the disease. It is said, however, that in some cases of tertiary syphilis the semen is still infective.

The period which elapses between the introduction of the virus into the body and the first evidences of local symptoms, usually lasts for three or four weeks. The time may be shorter or longer. In thirty-one artificial inoculations collected by Bäumler, the shortest period of incubation was ten, and the longest forty-four, days. When uninfluenced by treatment, secondary symptoms usually develop from within six to eight weeks after the appearance of the primary sore. Tertiary symptoms develop in some cases many years after the disease was originally contracted, and after a period of good health has intervened. Not infrequently they are the cause of permanent damage to health, and of death itself.

In both men and women primary lesions may escape unnoticed, secondary or tertiary symptoms being the earliest recognizable evidences of the disease. Then, again, there may be only primary symptoms, and no others. In women the primary sore is often much less evident than in men, and much more apt to escape detection. It may consist merely of a parchment-like thickening of the mucous membrane without irritation, or it may be situated in the urethra and masked by a gonorrhœa. It may be in the rectum, on the tongue, tonsils, *os uteri*, or vaginal mucous membrane. A stricture of the rectum in a woman is particularly suggestive of syphilis. There may be no visible lesions at any time, and no characteristic symptoms may appear before the climacteric. Then a peculiar cachexia may develop, its latent existence being apparently aroused by the strain and exhaustion incident to physiological changes.

MUST THE PARSON PAY?

IN the "good old time" when physicians were constrained to accept in a shamefaced way a so-called honorarium for their services, our clerical brethren wisely refrained from putting us to the blush by offering sordid cash for our labors. At the present time compensation for professional attendance is a matter governed by business principles. Sentimental squeamishness has died a natural death. Medical bills are universally sent, and their payment can be enforced by the ordinary process of law. Of course there are, and properly should be, intimate relations between all the liberal professions. The law, the church, and medicine are always in the very vanguard of modern civilization. Nevertheless, it is fully understood that when a lawyer needs a doctor, and *vice versa*, compensation for services rendered is expected. So, too, when a medical man gets married, or baptized, or buried, the officiating clergyman expects and obtains his remuneration without professional discount. Why is it, then, that in the precisely similar case of medical attendance on ministers a discrimination is still made in favor of the cloth? The salary and other income of a popular preacher is often vastly in excess of that of the doctor who

treats him for nothing. There is no good reason why it should be so. There may be an implied understanding that the minister is to reciprocate favors by turning back to his medical friend those erring sheep who might be tempted to try an "outside" physician. But this is clearly undignified, and to sensitive souls should prove an irksome bondage.

Even our slowly moving British cousins are beginning to chafe under a continuance of the time-honored system of gratuitous attendance on the clergy. In the *British Medical Journal* of March 10, 1894, a bold stand is taken against this custom. Our contemporary asserts that indiscriminate gratuitous attendance on ministers of religion and their families should no longer obtain. It is neither in the true interest of the minister nor in that of the practitioner. The reasons are given as follows:

First. Such a practice is inexpedient on the part of the minister, inasmuch as he cannot well, under the circumstances, have a free choice of practitioners and *de facto* make an independent selection of his medical attendant, nor readily effect a change should he become dissatisfied therewith, neither can he morally insist on such attendance as he may wish or deem necessary. If, for instance, he sends for the one of his choice—a popular doctor mayhap—at an opportune time and more or less disengaged, he would no doubt receive prompt and courteous attention. Should he, on the other hand, happen to send when the practitioner is tired and weary, or the weather cold and inclement, or during the night, it may be that the doctor, on finding who it is that wants him, would elect to remain at home; whereas, if it were not for the irrational custom in question of according gratuitous attendance, his professional services would have been willingly rendered.

Again, inasmuch as the minister would, where the unwise practice still partially lingers, have to regard the attendance of the doctor simply as an act of benevolent professional courtesy, he in return for such would, as a matter of course, have to select as his medical adviser a member of his own church rather than, possibly, a more able practitioner of another denomination. Moreover, since he is not to attach a monetary value to the doctor's services, but merely to incur a moral obligation, if he be a man of feeling and delicacy he would be restrained from saying to him: "Doctor, just call at my house this morning, will you?" but it will be: "If not too busy, will you please to call at my house some time to day?"

Further, when a medical man's services are needed they are generally wanted with as little delay as may be, and if you deprive the patient of the moral right of enjoining prompt attention you may almost as well inhibit him sending for one. A minister, moreover, by accepting (even as an assumed prescriptive right) the gratuitous services of a medical practitioner, places himself in the anomalous position of—so to speak—a clerical mendicant, and must act accordingly; in fact, he appears before the public as a beneficiary, and thereby not unnaturally incurs to a greater or less extent a loss of the respect due to him from the community.

Again, in the true interests of religion the minister's stipend should at least be adequate to defray the ordinary and needful expenses of living and to compensate others for essential services; for if the stipend be very limited and insufficient for his bare subsistence, it would necessitate him seeking as suppeditary to his ministerial functions a congenial vocation by which he could add to his pecuniary resources, but at a sacrifice of time that should be devoted to the sacred duties of his mission. Under the assumed prescriptive usage in question, moreover, if a minister or his family lost confidence in the attendant doctor, it would be found not a little embarrassing to call upon him to discontinue his attendance and supersede him by another; whereas if it were based on a *quid pro quo*, or, in other words, pecuniary remuneration, the desired change could be more readily effected.

Second. The alleged prescriptive custom, moreover, is morally objectionable from its effect on the practitioner. Although no medical man should practise his profession merely for its money value, still but very few could afford to pursue it without remuneration. Even admitting that the exceptional idea of gratuitous attendance did not originate in the natural desire to secure the moral and social influence of the clergy—in other words, a reciprocity of benefits received—nevertheless, such is the practical working of the custom, and constituting, as it does, a pernicious and deceptive system of practice, is derogatory to the profession. The attendance of a medical practitioner in a case of illness should be based either on a purely charitable or the ordinary remunerative principle, with a like deep interest under either circumstance in the successful treatment thereof.

In concluding these remarks it seems pertinent to ask, Why should hard-worked and ill paid medical men, any more than other business men, be expected to render payless, yet often priceless, services, or otherwise specially contribute to the essential personal needs of ministers of religion and their families? Be the answer what it may, it is difficult to see the justice or reasonableness of such a custom, and the members of the faculty would act wisely in simply carrying out the principle laid down in the suggested rule, which, after being submitted to and approved by divers eminent representative practitioners (including the late Sir Thomas Watson, the clergy's friend), was published in the *British Medical Journal* several years ago, to the following effect:

"That, in respect to charges for professional attendance on the clergy, beneficed or unbeneficed, there is no special general rule other than the simple 'unwritten' one (a time-honored and 'true Samaritan' principle, alike applicable to other classes), by which the faculty have long been self guided, namely, although fully and justly entitled to a commensurate remuneration for professional services accordant with the patient's position in life, to, nevertheless, make a greater or less reduction according to the circumstances of the individual case to such as may fairly be classed among the 'poor clergy' (beneficed or unbeneficed), specially so called, in contradistinction to the well endowed and independent clergy, which latter should be charged as ordinary and not exceptional patients; by a conscientious fulfilment of which advisory rule the medical faculty will, as a profession, have discharged their moral obligations to the ministers of religion."

We have quoted at length from our British contemporary, because its comments apply with equal force to England and America. Paupers of all kinds will ever commend our willing gratuitous treatment. But when the parson is no pauper, let the parson pay.

THE COMPARATIVE MORTALITY OF MAN AND WOMAN.

Although woman has been deprived of so many rights and privileges, she has at least the advantage of man as regards longevity; she suffers less from accidents, injuries, and many forms of disease; she is in fact more tenacious than man of the limited enjoyments allowed her.

Dr. Brandreth Symonds has collected and studied a large number of statistics to illustrate this interesting fact (*American Journal of the Medical Sciences*). The comparative mortality of the sexes at different ages, shows that in the first year of life the mortality of the female is much less than that of the male, being at birth 92.64 per 1,000 as against 112.80, and at the end of the year, 31.88 as against 35.08. This difference continues up to the fourth year.

From five to twelve the female mortality is greater than that of the male, being at the latter period 3.56 for males, and 4.28 for females. At the age of forty-six the male mortality equals that of the female, the latter having been up to this time slightly in excess. During the years forty six to fifty-six, the period of the climacteric, the male mortality gains rapidly on the female, being 6.32 per annum for the one and only 3 47 for the other. Hence the climacteric is really a much more serious time for man than for woman. After fifty six, the female mortality gains on that of the male, but is always slightly below it. Woman has not only a less mortality and a greater longevity than man, but there is, according to Dr. Symonds, a plurality of female births, though the contrary view is usually held. Nature seems determined to keep up a full supply of women, a condition which, it is suggested, may be the result of the polygamous habits of primeval man.

THE DRINKING TREATMENT FOR TYPHOID.

Some years ago M. Debove recommended the use of large amounts of water internally in typhoid fever. "I make my patients drink," he said; and this was his chief special treatment. The object was to dilute the fluids of the system and wash out the toxines in the blood and intestinal canal. M. Lichteim adopted this treatment and reports nine successful cases. Recently M. Maillart, of Geneva, has made an elaborate study of this mode of treatment, reporting fourteen cases in detail, of which one died. (*Revue de Médecine*, November, 1893, and March, 1894.) Maillart thinks that the water-drinking method should be "erected into a special method of treatment." In order to secure the proper results the patient must drink five or six litres (quarts) of water a day. There is no contra indication for the use of water in this way, for it does not weaken the heart, but has rather the contrary effect. The results obtained are a progressive lowering of the fever, a disappearance of dryness of the mouth, a marked sedation of all the nervous symptoms, and an improvement in the action of the heart and kidneys. There is an abundant diuresis and an unusual increase in the perspiration. Urea is carried off in large amounts. The treatment does not shorten the course of the disease, but simply makes it milder and less fatal. Patients, we are told, take kindly to this method.

The typhoid patient takes usually six to eight glasses of milk daily, and if to this are added ten to twelve glasses of water, the diluent effect should be very great.

News of the Week.

Protection for the Red Cross.—It is reported from Washington that the House of Representatives has passed the bill to protect the insignia and the name of the Red Cross Society. The bill was introduced seven weeks ago by Mr. Cogswell, of Massachusetts. It was referred to the Committee on Foreign Affairs, by whom it was unanimously reported. In the preamble to the bill the story is told of the formation of the society. It states that on August 22, 1864, plenipotentiaries, respectively representing Italy, Baden, Belgium, Denmark, Spain, Portugal, France, Prussia, Saxony, Wurtemberg, and Switzerland, met at Geneva and agreed upon ten articles of a treaty, the purpose of which is to mitigate the evils inseparable from war, particularly providing that persons employed in hospitals and in affording relief to the sick and wounded, shall be deemed neutral and entitled to protection, and that a distinctive flag shall be adopted for hospitals and ambulances, and an arm badge for the individuals thus neutralized. The treaty, which was subsequently ratified by thirty six nations, including the United States, provides that the especial insignia of the society shall be a red Greek cross on a white ground. The bill states that the unauthorized use of the insignia has become a source of embarrassment to the society in time of war, and it provides, therefore, that after the passage of the bill it shall be unlawful for any person to display the symbol of the society, or use as a trade mark or as a designation the words "red cross" or any expression liable to be mistaken therefor. Every violation of this provision shall be punished by a fine of not less than $50, nor more than $500, or by imprisonment not exceeding six months, or by both such fine and imprisonment, the fine so collected to be paid to the society. All persons who have adopted the Red Cross as a trade mark shall discontinue its use within one year, or be liable to the foregoing fine and the confiscation of the articles so designated. The society may, however, permit the use of their insignia for a consideration of not less than $500 in each case. Any person not directly connected with, or authorized by, the society, attempting to make collections of money or goods in the name of the Red Cross is subject to a fine and imprisonment. Knights Templar, Masons, or the Sixth Corps of the Army, who adopted the Red Cross insignia prior to August 22, 1864, are exempted from the foregoing provisions.

Statistics of the Attendance of American Medical Colleges.—Whatever may have been the fact as to the number of students of medicine at some remote period, it has not been true, for the last half-dozen years or more, that the number is (in relation to population) "relatively diminishing." At the sessions of 1885 the total attendance was 10,891—9,245 regular, 1,032 homœopathic, 614 eclectic. During the sessions of 1893, the attendance was 18,910—16,759 regular, 1,410 homœopathic, 741 eclectic. These figures show gains in eight years of 73.6 per cent. in the total attendance—81.2 per cent. for the

regular students, 30.6 per cent. for the homœopathic, 20.6 per cent. for the electics—an average annual increase of 9.2 per cent. during the period. The average annual increase of population during the same period was less than 2.5 per cent. So that instead of there being a diminution of students of medicine in relation to population there is a relative increase nearly four times greater than that of population. As a matter of practical interest to the profession, it may be noted that there is an average increment of nearly 6,000 new home made physicians every year, and that while the population increased 24.8 per cent. during the decade 1881–1890, the number of newly graduated physicians increased over fifty per cent. during the same period; last year, 1893, the increase was a trifle over eight per cent.—*Journal of the American Medical Association.*

Death of Professor Corydon L. Ford.—Corydon L. Ford, M.D., LL. D., died in Ann Arbor, Mich., last week, aged eighty-one years. For forty years Dr. Ford was Professor of Anatomy and Physiology in the University of Michigan and was one of the best known anatomists in America. He was born in New York State in 1813, and graduated from Geneva Medical College, New York. He received the appointment of demonstrator of anatomy at the college on the day of his graduation, and at the same time had charge of the anatomy departments at the medical colleges at Buffalo, N. Y., and Castletonville. In 1884, when the medical department of the University of Michigan was organized, he accepted the appointment of demonstrator of anatomy, which chair he had held since. He had delivered nearly two hundred courses of lectures in the leading medical colleges in the United States.

The Montclair Epidemic of Typhoid Fever.—About seventy cases and twelve deaths have been reported up to date of writing. The newspapers have made much of what has really been less serious than many mild epidemics of scarlet fever or diphtheria, that attack our suburban towns every year. The idea of placarding houses that have typhoid fever cases as proposed by some sanitary newspaper reporters, is most ridiculous.

A Commission for Investigating Tuberculosis among Cattle.—A bill has been introduced into the New York Senate, providing for a further inquiry into the existence of tuberculosis. The wide prevalence of consumption in cattle has been a question of much concern to the State Board of Health, and last year the board's inspectors killed over twenty thousand head of cattle which were afflicted with the disease, and for which claims aggregating thousands of dollars are being filed daily by the State Board of Claims. The new bill provides for a commission to consist of one member of the State Board of Health, to be designated by said board; three breeders of thoroughbred cattle, each engaged in the breeding of a separate and distinct breed, to be selected by the Directors of the New York State Dairymen's Association, and Professor James Law, Professor of Veterinary Medicine in Cornell University. The commission is to have all the power now granted to the State Board of Health to examine the cattle of the State for the disease known as tuberculosis, and to examine into that disease, its existence, and any other facts concerning it that may now or hereafter be brought forth, and report the same to the Senate by January 15, 1895, setting forth all work done and all experiments made, and such suggestions for the proper continuation of the work as will tend to remove the disease from the cattle of the State. Fifteen thousand dollars is appropriated for the expenses of the commission.

American Medical Association.—The Committee of Arrangements announces that the rate of fare for tickets from Missouri River points, including Sioux City, Council Bluffs, St. Joseph, Atchison, Leavenworth, and Kansas City, to San Francisco and return *via* the Trans-Continental roads, at the time of the meeting of the American Medical Association, will be $65.50. From St. Louis, Cairo, Memphis, and New Orleans, the rate will be $77.50. The going trip must be made within fifteen days from the date of sale of tickets, and the return trip within fifteen days from the day upon which the tickets are signed in the presence of a railroad agent, but in no event later than July 15th. Within the State of California the fifteen-day limit is ignored on both going and returning trips, *i.e.*, the holders of tickets are at liberty to move at will within the State of California within the life of the tickets, and the fifteen-day limit returning is not enforced west of the terminals at Portland, Oregon, and El Paso. If the Shasta route between San Francisco and Portland is passed over on either going or returning trip from Missouri River, St. Louis, or Chicago, the rate will be $15 greater. Efforts are being made to obtain a similar reduction in rates on the Eastern railroads.

State Board of Health Reform.—The investigation into the affairs of the State Board of Health by the Senate special committee having been concluded, Senator Smelzer, the Chairman of the Committee, has introduced a bill reducing the membership of the State Board of Health from nine to three, to hold office one, two, and three years, respectively. It provides that the Commissioners shall be appointed by the Governor by and with the consent of the Senate, and that not more than two shall be of the same political party. The President of the board, who is to be one of the Commissioners, shall receive a salary of $3,000, and the other members, salaries of $2,000. The Secretary of the board shall receive a salary of $1,800. The registration of the vital statistics is abolished, and the reports of such statistics are to be bound in book form for reference. This change alone would save about $9,000. None of the members of the present board receives a salary, while the salary of the Secretary now is $4,500. The proposition to discontinue the registration of vital statistics is a most singular one. If such registration is done thoroughly it is one of the most valuable kinds of work that can possibly be done. Instead of abolishing it the State should vote money to increase its efficiency.

Medical College Commencements.—The Southern Medical College of Atlanta, Ga., held its annual commencement April 2d, and awarded diplomas to forty-two graduates.

The Miami Medical College (Cincinnati) held its annual commencement April 4th, and awarded diplomas to twenty-two graduates.

The McGill University of Montreal, Quebec, held its commencement exercises April 5th. Fifty-five graduates received the degree of M.D.

The fifteenth annual commencement of the St. Louis College of Medicine was held March 27th. Twenty graduates were awarded diplomas.

The fourth annual commencement of the Kansas Medical College (Topeka) was held March 28th. There were seven graduates.

The Medical College of Indiana, at Indianapolis, held its twenty-fourth annual commencement March 26th, and awarded diplomas to fifty-two graduates.

The Woman's Medical College of Cincinnati held its commencement exercises April 2d. Fifteen received the degree of M.D.

At the thirteenth annual commencement of the Omaha Medical College seventeen graduates received their diplomas.

The annual commencement of the medical department of the University of Oregon (Portland) was held April 2d. There were fourteen graduates.

Reviews and Notices.

Treatment of the Diseases of the Stomach and Intestines. By Dr. Albert Matthieu, Physician to the Paris Hospitals. New York: William Wood & Co. 1894.

This excellent book contains a general summary of the exact diagnosis and therapeutics of the diseases of the stomach and intestines. Of late years we have learned to put much stress on the condition of the chemical function of the stomach. Although M—— has made use of these newer methods in a most thorough way, he has, nevertheless, by no means neglected the clinical symptoms as the best aid for diagnosis. This point appears to be of great value, especially for the practitioner who is at times doubtful whether to examine the stomach chemically.

The book contains a chapter on semeiological technique, in which are described the principal methods employed for the examination of the contents of the stomach, of the fæces, and of the urine. Then a chapter on the diet suitable in gastro-intestinal dyspepsia. Speaking on the diet in diarrhœa, the author gives the following very salient points:

"The general indication here is to reduce the mass of food in the intestine, and especially to remove as far as possible from the diet all those substances which leave a large indigestible residue to act as an irritant to the intestinal mucous membrane. We must prescribe a diet that contains a large amount of nourishment in small compass, and this excludes green vegetables at once. We should advise the taking of those articles which possess astringent properties, and proscribe those which are laxative in their action. In regard to these points there are often individual idiosyncrasies which we must inquire into and respect when learned. Finally, we must endeavor to prevent as far as we can, by means of appropriate food, intestinal fermentation and the further elaboration of toxines by the food undergoing digestion.

"Milk may render great service in the treatment of many forms of diarrhœa. It is a complete aliment, liquid in form, and little liable to putrescent decomposition. We may, according to circumstances, prescribe a partial or an absolute milk diet; and sterilized milk often, especially in infants, gives better results than the natural fluid.

"Eggs are frequently employed, and rightly, for they afford a large amount of nourishment in small volume. Albuminous water may also be given as a beverage; its beneficial action, while not thoroughly understood, is nevertheless very real."

As regards gastro-intestinal antisepsis, the author makes the following potent remarks: "Sufferers from auto-intoxication should be allowed to take only perfectly sound articles of food, and those which are least liable to become the seat of putrid fermentation within the intestine. This process is especially favored by two conditions, viz., an excessive quantity of food, particularly of nitrogenous food, and the presence of a considerable amount of indigestible residue.

"A milk diet fulfils these two indications admirably. It introduces into the digestive tract but a very small proportion of toxines or of micro-organisms, and it leaves a minimum quantity of waste material; it is also easily elaborated and easily absorbed, and furthermore increases the urinary secretion. This is an explanation of its good effects in diarrhœa, enteritis, etc. It is justly entitled to the first rank among foods suitable for those cases in which auto intoxication plays an important part in the production of the morbid symptoms. Nevertheless milk may itself furnish a vehicle for the introduction of pathogenic microbes, of the coli bacillus, or the bacillus of lactic-acid fermentation, which latter, as Wurtz and Leudet have shown, may occasion the production of toxines by its action upon albuminoid substances. For this reason great care should be taken to see that the milk is fresh, comes from healthy animals, and is as far removed as possible from all causes of fermentation.

"Sterilized milk represents the ideal aliment, and it has been found to give excellent results in the treatment of diarrhœa, especially in children. All patients cannot be subjected to an absolute milk diet, for various reasons, but in any case it constitutes a valuable addition to a mixed regimen."

This so timely and instructive book will prove of great service to the medical profession.

Syphilis in the Innocent (Syphilis Insontium). Clinically and historically considered, with a plan for the legal control of the disease. By L. Duncan Bulkley, A.M., M.D., Physician to the New York Skin and Cancer Hospital, Consulting Physician to the New York Hospital, etc. New York: Bailey and Fairchild, 29 Park Row.

The author has here gathered more facts and figures bearing upon the question of syphilis, as a non-venereal disease, than have ever before been published, or in all probability, attempted. In so far as it is valuable to have this knowledge collated, classified, and preserved in book form, the work is an important one, and the labor involved in its preparation must have been very great. Its practical value is, however, disproportionate both to the size of the work and the time and trouble it has taken to write it. Innocent syphilis has been discussed from so many standpoints that physicians are, as a rule, quite well up in the subject, and the sum total of their working knowledge is not going to be much increased by the perusal of an analytical bibliography which teaches, at the most, that many men (say one thousand) have observed non-venereal chancres, and that some of them have had the good fortune to treat many cases. The author gives the histories of one hundred and sixteen personal instances of extra-genital infection, but after reading a few of each regional variety, one feels that they can serve as samples of the whole, and is inclined to pass on to the more interesting history of the one hundred epidemics which have occurred since 1577. Here are to be found some carefully prepared and chronologically arranged tables which will serve future writers as a means of ready reference.

The plan for the legal control of syphilis, in Chapter X., is somewhat disappointing. This is the most important and most practical question touched upon in the whole work; and the suggestions put forward, while they are all good, are none of them new. Still, if coming with all this backing of data, laymen and legislators can be helped by them to look upon syphilis more in its non-venereal aspects, so as to put the disease under proper health-board control; if it can be made "criminal to transmit syphilis wittingly;" and if "examining the men

instead of the women" can be carried out and a check thus put to the spread of syphilis through prostitution; then a great work, indeed, will have been accomplished.

A Practical Treatise on Medical Diagnosis for Students and Physicians. By John H. Musser, M.D., Assistant Professor of Clinical Medicine in the University of Pennsylvania. Pp. 881. 162 woodcuts and 2 colored plates. Philadelphia: Lea Brothers & Co. 1894.

Modern methods of medical teaching and study have rendered treatises like the present an absolute necessity. All of them necessarily duplicate each other somewhat, but each bears the impress of its author's personality. The present work is to be commended alike for its logical arrangement, accurate observation, and clearness of expression.

It is divided into two main parts: "General Diagnosis," covering 186 pages, and "Special Diagnosis," 674 pages. Under the former heading are chapters on general observations, data obtained by inquiry, data obtained by observation, bacteriological diagnosis, examination of exudations, transudations, and cystic fluids, and one on the morbid processes and their symptomatology.

In the second part the various regions of the body are taken up seriatim and systematically gone over, according to the scheme already outlined. The chapter on bacteriology is especially commendable, because it contains everything practically necessary for clinical work and yet it is not too much lumbered up with useless formulæ or directions.

A physician's ability is measured not so much by th amount of his knowledge, as by his power to use what h knows. To develop this practically is the province o such works as that of Dr. Musser. To him we exten our congratulations upon the successful performance o his task. The publishers have given the volume an a tractive setting.

The Technique of Post-mortem Examination. By Ludwig Hektoen, M.D., Pathologist to Cook County Hospital, Professor of Pathological Anatomy, College of Physicians and Surgeons, Chicago. With Forty-one Illustrations. Chicago: W. T. Keener Company. 1894.

This little book is designed to serve as a guide for those unacquainted with the technique of post-mortem examinations. It is very practical, full of good points, and fully carries out the objects of the author. The illustrations are very neatly executed.

Politzer's Text-book of the Diseases of the Ear and Adjacent Organs. For Students and Practitioners. Translated by Oscar Dodd, M.D., Assistant Surgeon at the Illinois Charitable Eye and Ear Infirmary; Clinical Instructor of the Eye and Ear in the College of Physicians and Surgeons, Chicago. Edited by Sir William Dalby, F.R.C.S., M.B. Cantab., Consulting Aural Surgeon to St. George's Hospital. With 330 original illustrations. Philadelphia: Lea Brothers & Co. 1894.

This standard treatise, by a recognized German authority, will be eagerly welcomed by those English readers unacquainted with the work in the original. Politzer's views on most otological subjects are those of an advanced yet conservative surgeon. His advice is that of a careful observer of vast and varied experience. The illustrations accompanying the text are good. The translator deserves credit for his accuracy in conveying the author's meaning.

Climates of the United States in Colors. Popular Edition of Denison's Charts, with Additions. By Charles Denison, A.M., M.D., Denver, Col. Published by The W. T. Keener Company, 96 Washington Street, Chicago, Ill. 1893.

This is a highly instructive book with twelve charts. Annual cloudiness, rainfall, chart of annual winds, hypsometric seasonal isotherms, and wind indications among others.

It will serve an important purpose in aiding those unacquainted with the most important hygienic measures in the therapeusis of pulmonary disorders, namely, climate.

The tables are very accurately compiled, and all in all it sh

The lectures forming the basis of this syllabus are those delivered by Professor Barton C. Hirsh, M.D. While the volume is primarily of interest to the students of only one institution, it will serve very good as a "memory-refresher" for anyone who is about to be examined in this branch of medicine.

A Manual of Therapeutics. By A. A. Stevens, A.M., M.D., Instructor in Physical Diagnosis, University of Pennsylvania. Pp. 435. Philadelphia: W. B. Saunders. 1894.

Successive chapters treat of action of drugs, applied therapeutics, incompatibility, etc. The remedies of the Pharmacopœia are followed alphabetically. An index of drugs and an index of diseases close the book.

Nothing new is presented, and this work, while up to the average of its kind, is merely a duplicate of various others on the market. Students will find it useful to guide their third year reading in this subject.

Transactions of the American Orthopedic Association. Seventh session, 1893. Vol. VI. Philadelphia: Published by the Association. 1894.

This solid-looking volume of transactions contains thirty-three papers, covering a wide variety of topics, ranging from "soft corns" to "fragilitas ossium." The discussions are condensed, and a vast amount of information is compressed into 275 pages.

The Healing of Rodent Cancer by Electricity.—By J. Inglis Parsons, M.D., M.R.C.S., M.R.C.P. (Lond.). Honorary Fellow, American Electro-Therapeutic Association; Fellow Royal Medical Chirurgical Society, etc. London: John Bale & Sons. 1893.

This little volume gives the author's results of treatment. The disease and the means of cure advocated are both so definitely circumscribed that, were the cases more numerous and the length of time from reported cure longer, the method would meet with greater favor than we fear it will from the reading of this monograph alone.

Society Reports.

ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

Held in Rome, April [illegible]

Bichromate of Potassium in Gastric Affections.—Dr. Thomas R. Fraser, of Edinburgh, had for many years treated cases of gastric disease with bichromate of potassium. The cases included catarrh of the stomach, chronic gastric ulcer, gastrodynia, and even dilatation and malignant disease. In the two latter some of the symptoms were occasionally relieved, and in the others the symptoms were as a rule entirely removed. Bichromate of potassium appears to exert its beneficial and curative influence not only by reason of its antifermentative action, but, even more conspicuously, in virtue of a direct or indirect analgesic effect. It is probable also that certain histological structures in the stomach wall are selectively modified by it. The doses employed by the author were from $\frac{1}{12}$ to $\frac{1}{6}$ grain given thrice daily one or half an hour before eating.

The Comparative Situation of the Stomach in Men and Women in Diseased Conditions.—Dr. Bourget, of Luzerne, read a paper with this title, in which he said that gastric ptosis is much more frequent in women than in men. In the case of the male subject it is simple dilatation of the stomach which prevails.

Treatment of Hyperchlorhydria.—Dr. Cantù, of Pavia, said that he had had occasion to give duboisine as a calmative of gastro-intestinal pains, and was led thereby to a study of the physiological action of this drug upon the gastric functions. He found that it caused a marked diminution in the acidity of the stomach contents, reducing it about one-half. Analysis made by Siöquist's method showed that this decrease in acidity was due chiefly to a diminished secretion of hydrochloric acid. Duboisine would then be indicated in all gastric affections characterized by an exaggerated glandular secretion, or rather, he would say, by an increased formation, of HCl. The excellent results obtained by the author from the administration of the drug in such cases was a practical confirmation of his experimental conclusions. The action of duboisine is very far superior to that of atropine. The dose of the hydrochlorate employed was $\frac{1}{10}$ to $\frac{2}{3}$ milligramme hypodermically, or $\frac{1}{5}$ to $\frac{1}{10}$ milligramme by the mouth. The action of the remedy ceased to be noted twenty-four hours after the administration of the last dose.

Treatment of Gastric Catarrh.—Dr. Amalfi, of Naples, said that catarrh of the stomach, especially in its chronic form, is one of the most common of the affections from which the Neapolitan suffers, and unfortunately is one that is almost always neglected. Its causes are the hot climate, a too copious and too exclusively farinaceous diet, an immoderate use of drugs, and above all, constipation. The only treatment of any avail in this affection is lavage effected by means of Fancher's apparatus.

Apical Pneumonia.—Dr. Antonino Fienga, of Naples, read a paper on this subject, of which the following were the conclusions: 1. Pneumonia of the apex is a common disease and may be epidemic. 2. Among other characteristics of the affection is a tendency to manifest itself at a period somewhat remote from the infection. 3. It may be preceded or followed by other infections, by intestinal or meningeal localizations, and by nervous manifestations which may prove dangerous to life. 4. A few exceptional cases apart, it is a curable disease. 5. Paralysis, deafness, blindness, aphasia, and even mania are the sequelæ most to be feared during the process of resolution. 6. The best remedies for the cure of the disease and its complications are quinine, salipyrine, ethylic alcohol in aromatic water, digitalis, Neapolitan ointment, ice-bags, bromides, and oxygen. 7. The sequelæ yield to long-continued mercurial frictions, to the administration of the iodides, and to suspension.

Treatment of Fibrinous Pleurisy and Pericarditis.—Dr. E. De Cérenville, of Luzerne, presented a communication with this title, in which he advocated the application by injection to the surfaces covered with the fibrinous deposit of sterilized carbolated oil. In this way the painful friction between the inflamed surfaces is reduced to a minimum.

The Treatment of Empyema in Tuberculous Patients.—Dr. Charles Bäumler, of Freiburg i. Br., presented a communication with this title, of which the following were the main points insisted upon: I. In the early stages of empyema, and when the patient's condition before the appearance of this complication was not already hopeless, the following treatment is advised: 1. When pus microorganisms are present, thoracotomy; 2. When these are not found, the treatment must be at first expectant. If the increasing amount of the exudate causes threatening symptoms aspiration must be practised and repeated until the suffocative symptoms subside; then, when the general condition is good or perhaps better than it was, the radical operation (thoracotomy) is to be performed, provided the lung is found to be still capable of expansion and not too profoundly involved in the tuberculous process. II. In empyema of long standing: 1. The treatment above sketched; 2. When cough, dyspnœa, and cyanosis persist after the removal by puncture or aspiration of perhaps several hundred cubic centimetres of pus, showing a very defective expansive power of the lung, if the patient is in fair strength a radical operation must be made (thoracotomy or Bülan's operation). 3. When the power of expansion of the lung is very greatly impaired, the general condition being good, however, and in the absence of fever, we must resort to palliative measures, such as punctures repeated as may be indicated by the mechanical action of the exudation—finally, perhaps, to Bulan's siphon drainage. 4. When the general condition is bad in consequence of the pulmonary disease or of complications (amyloid degeneration, intestinal tuberculosis, etc.), palliative measures only are admissible.

Treatment of Empyema.—Dr. S. Laache, of Christiania, favors resection of the ribs in these cases, which is, he thinks, the most certain method of obtaining a cure in suppurative pleurisy. The principle of treatment, based upon as complete drainage as possible, is thereby realized in the most perfect way, and when this thorough drainage is obtained, we may, without danger, dispense wholly or in great measure with the laborious process of

washing out the thoracic cavity. In his communication the author spoke of those complications which are the most grave from a medical point of view, and more particularly of the condition of extreme debility which may follow the operation, and of sudden death, which is sometimes a result of this procedure.

Intestinal Adhesion in Middle-aged Patients.—Dr. Arthur Faenicke, of Breslau, read a paper with this title. In sixty to seventy per cent. of women between twenty and forty years of age, who are set down as hysterical because their complaints are of an undefined character, a careful examination of all parts of the abdomen, he said, would reveal the presence of old peritoneal adhesions between different segments of the intestines. These can be discovered only by the most careful examination, made when the intestine is empty and again when it is partly full.

The cause of these adhesions is, in the large majority of cases (seventy-five per cent.), some inflammatory process originating with the internal sexual organs, and running its course for the most part unobserved, after the subsidence of the primary affection. Of the remaining twenty-five per cent., about half the cases are sequelæ of perityphlitis, the balance being the result of repeated attacks of gall-stone colic with peritoneal irritation, or of gastric or intestinal tumors.

The treatment consists in regulation of the diet, the securing of regular evacuations of the bowels, the promotion of absorption by means of external counter-irritation to the abdomen (blisters, etc.), and the management of the acute exacerbations by local blood-abstraction.

The Influence of Temperature upon Intestinal Fermentation.—Dr. Luigi Cantù, of Pavia, said that he had several times observed a syndroma of phenomena consisting essentially in severe and painful cramps of the stomach, nausea, vomiting, wandering abdominal pains, borborygmi, slight fever, etc. At the same time the skin of the entire body was covered with the characteristic eruption of urticaria. The troubles disappeared completely in four or five days. The symptoms were referred by the author to auto-intoxication of intestinal origin, caused by an exaggerated peristalsis of the stomach, and secondarily of the intestine, excited by rapid oscillations of the atmospheric temperature acting upon the abdominal region. He had observed the same morbid complex in persons who had slept with abdomen uncovered in a room, the window of which was open during the night. Upon measuring in these individuals the intensity of the fermentative processes by the dosage of sulphonic ethers in the urine, he had found these processes always greatly increased. He had found, however, that the application of ice bags to the abdomen retarded digestive fermentation to a marked degree, and this would furnish an indication for their use in attacks similar to those above described.

The Management of Fevers and Particularly of Typhoid Fever.—Dr. Burney Yeo, of London, presented a communication with this title of which the following were the conclusions: 1. Recently acquired knowledge as to the nature and causes of specific fevers demands a modification in the therapeutic conceptions and indications applied to their management. 2. To counteract or antagonize the pyrogenic and other poisons, secreted by micro-organisms introduced into the body from without is an essential therapeutic indication in the treatment of fevers. 3. The investigation into the existence, scope, and activity of such counteracting therapeutic agents is of paramount importance to the rational treatment of fevers, and already the results of clinical observations give promise of fruitful conclusions to researches in this direction. 4. The search for direct antagonists to the poisons of specific fever is as important and probably of as great practical advantage as is that for methods of producing immunity. 5. The course and character of specific fevers can be, and have been, favorably modified and influenced by the administration of such antagonists. 6. Certain specified methods commonly adopted in the management of fevers, and especially of enteric fever, require modification and correction (*a*) in the direction of diet and regimen, and (*b*) in the direction of drug treatment.

Treatment of the Typhoid State.—Dr. Juhel-Renoy, of Paris, read a paper on this subject, of which the following were the main points: All infectious diseases may assume the typhoid aspect, and when this occurs refrigerant treatment is indicated. The method of this refrigerant medication must vary according to the result which it is desired to obtain. It is vastly superior to any other procedure in all forms of infectious fever; it reduces the total mortality of typhoid fever to seven per cent.; of typhoid erysipelas to nine per cent.; of malignant scarlatina to fourteen per cent; of ataxo-adynamic measles to an almost inappreciable figure. The mortality of adynamic grippal pneumonia is reduced one-half by cold baths, and smallpox, when treated in this way from the start, is much milder in its course. The ways in which cold baths bring about the disappearance of the typhoid condition are numerous, but that which seems to be the most important as well as the most constant is the urinary crisis, an indication, when it occurs, of an early cure.

Typhoid Bacilli in the Gall bladder—Dr. H. Chiari, of Prague, read a paper on this subject, in which he said that the systematic bacteriological examination of the contents of the gall bladder in cases of enteric fever almost always revealed the presence of typhoid bacilli. The bacilli may increase in numbers here and induce an inflammation of the gall-bladder, and possibly there is in this fact an explanation for certain cases of relapse in typhoid fever. The bacilli gain entrance either through the blood or by direct ascent through the common bile-duct from the intestine.

Pathogenesis of Diabetes.—Dr. Nicola de Domenicis, of Naples, read a paper with this title. Ligature of the duct of Wirsung, with complete cutting off of communication between the pancreas and the duodenum, produced diabetes, he said, just as surely as total ablation of the pancreas. The inclusion of even a third part of the pancreas in the subcutaneous connective tissue will not prevent the occurrence of diabetes in animals from whom the part of the organ remaining in the pancreas has been removed. The intestinal contents of animals from whom the pancreas has been removed, properly prepared and injected into the abdominal cavity of healthy animals, induces in them a slight and transitory glycosuria. The author concluded from the results of these experiments that pancreatic diabetes is due to the suppression of the intestinal function of the pancreas.

Hypertrophy of the Heart in Renal Disease.—Dr. de Domenicis also presented a communication embodying the results of some experimental studies made to determine the pathogenesis of cardiac hypertrophy in disease of the kidneys. From the results of these studies he arrived at the conclusion that hypertrophy of the heart in these cases was not the direct consequence of the renal disease, but that both affections were in equal measure the results of a common cause.

Pancreatic Changes in Diabetes.—Dr. David Hausemann, of Berlin, presented a communication on this subject in which he said that there was a form of diabetes occurring with and another form without pancreatic lesions. The pancreas may be destroyed by connective tissue or fatty overgrowth, by tumors or by calculi, and diabetes thereby result. In many such cases, however, so much of the pancreatic tissue may be preserved that no glycosuria is induced. The most frequent pancreatic lesion in diabetes is simple atrophy, and this is found in corpulent diabetic patients as well as in the emaciated, but is met with only exceptionally in other cachexiæ. The form of diabetes occurring with simple atrophy of the pancreas may be regarded as genuine pancreatic diabetes in contradistinction to the forms associated with other diseases of this gland which present more casual lesions.

Glycosuria of Nasal Origin. — Dr. L. Bayer, of Brussels, reported a case of glycosuria accompanied by other trophic symptoms which was caused by nasal obstruction, and disappeared after the re-establishment of free respiration through the nose. From this observation he came to the conclusion that an obstruction to nasal respiration may be a direct cause of glycosuria. The appearance of the glycosuria under such circumstances may be explained in part by the diminished absorption of oxygen, but especially by the resulting circulatory (asphyxic) and nervous (bulbar) troubles.

A New Method of Diagnosis and Prognosis of Chronic Nephritis.—Dr Basset, of Toulouse, said that as long ago as 1860 he had read a paper before the Medico-chirurgical Society of Toulouse, on "The Non-elimination of Odorous Substances by the Kidney, as Bearing upon the Diagnosis and Prognosis of Nephritis." Since that time he had found a new and more precise method of arriving at this end, namely, the employment of iodides and of the salts of quinine, the elimination of which by the kidneys is so rapid in the normal condition, and the comparative dosage of which may be made so exactly. The following were the conclusions of the communication: 1. The elimination of odorous substances by the kidneys is retarded, diminished, or abolished in chronic nephritis. 2. This examination of the odor of the urine is an easy and rapid method of ascertaining the functional condition of the kidneys and of determining their anatomical integrity or the reverse, and thus of arriving at a diagnosis and prognosis of Bright's disease. 3. The salts of certain substances which are ordinarily eliminated in great part and rapidly by the kidneys, such as the iodides, the bromides, the salts of quinine and the turpentines, which form with nitric acid a precipitate soluble in ether and alcohol, are very useful as furnishing in a precise manner, by the retardation or diminution of their elimination in the urine, data upon which to base a diagnosis and prognosis of the various degrees of chronic nephritis.

Percussion of the Kidneys. — Dr. Ernesto Bruschini, of Naples, read a paper in which he said that it was necessary to make an examination of the kidneys by means of percussion in all cases in which this was not rendered impossible by special grave conditions. It is not rare by so doing to discover the existence of a movable kidney which would not otherwise have been suspected, and when the symptoms presented by the patient would have led to an entirely different diagnosis. We cannot, however, without the aid of other symptoms, establish a diagnosis of movable kidney from the mere absence of percussion dulness on one side. We must first be sure that there are no pathological conditions in the other internal organs, especially the abdominal. Above all it is necessary to be cautious in making this diagnosis when there is a tumor of the spleen or of the liver, or when the stomach is markedly dilated.

Nephritis without Albuminuria in Specific Intoxications.—Dr. Antonino Fienga, of Naples, said that there existed cases of nephritis, as shown by the clinical and microscopical symptoms, in which no albumin was to be found in the urine. Such a nephritis may be due to the introduction of a specific virus from the external genitals reaching the kidneys through the lymphatics. The disease so caused may subside after rest, the institution of a milk-diet, or the administration of chloral, combined with adonis vernalis whenever the heart appears to be affected or œdema is very extensive.

Anasarca following Retention of Urine, but without Albuminuria. — Dr. Lépine, of Lyons, said that the dropsy sometimes observed in cases of retention of urine, especially in cachectic subjects, could be satisfactorily explained by the weakened condition of the tissues in the cachectic and by the fact of the retention of a superabundant quantity of fluid in the blood. The only thing that may seem extraordinary in such cases is the absence of albuminuria. From a number of experiments made upon dogs the author had found that the urine, greatly reduced in quantity and secreted against a counter-pressure of one metre of urine in the urethra, might be perfectly free from albumin provided this pressure were constant and not intermittent.

The Rôle of Arterial Aplasia in the Renal Complications of Infectious Diseases.—Dr. Emilio Conde Flores, of Caracas, Venezuela, read a paper in which he maintained that arterial aplasia might play a very important rôle in the production of the renal complications of acute or chronic infectious disease (typhoid fever, tuberculosis, etc.).

(To be continued.)

CONGRESS NOTES.

The Meeting of Virchow and Baccelli.—The foreign guest who received the most newspaper honor was Dr. Rudolph Virchow, of Berlin. His every movement, from the moment of his arrival in Rome to that of his departure, was chronicled as faithfully as if he had been one of the reigning sovereigns of Europe. The recital of his polite efforts to meet Dr. Baccelli was particularly impressive. The *Popolo Romano* reported this interesting event in the following terms: "As we announced yesterday, scarcely had the celebrated German clinician arrived in Rome when he repaired to the Ministry of Public Instruction to visit the Honorable Baccelli; but not finding him, he left his visiting card. The Honorable Baccelli, in his turn, as soon as he was aware of the arrival of his very dear friend, went in search of him, with no better fortune. Virchow, however, could not let the day pass without having met the Honorable Baccelli, and went a little later, with one of his Berlin colleagues, to the Honorable Baccelli's house in the Piazza Campitelli. When Antonio, the old valet of the Honorable Baccelli, announced Dr. Virchow, the Honorable Baccelli, who was writing in his study, although in his dressing-gown—his traditional ash-colored gown with red cord and tassels—without any ceremony, just as he was, left his secretaries and ran to meet his old friend. The meeting was most cordial, and a very affectionate conversation, lasting three-quarters of an hour, then took place between the two illustrious clinicians." What became of the Berlin colleague during this colloquy the reporter forgot to state.

Congress of Alienists.—The eighth congress of Italian Alienists was held in Rome during the two days preceding the inauguration of the International Congress. Many foreigners were present at the meetings. The opening address was delivered by Dr. Tamburini, the vice-president of the Association. Dr. Bonfigli, of Rome, was elected president for the ensuing year.

The Wives and Daughters of the members were entertained during the week by a committee of ladies resident in Rome. Numerous drives were taken and visits made to the principal churches, galleries, and other points of interest.

Many Clubs in Rome opened their doors to the members, the only requisite for admission being the presentation of the card of membership.

A Flight of Pigeons.—During the lunch at the Baths of Caracalla, given on the last day of the session, there was a flight of a thousand pigeons under the direction of the Carrier Pigeon Society of Rome.

Army Surgeons.—There were between one hundred and ninety and two hundred army surgeons from Europe and America in attendance at the Congress, in addition to those from Italy.

Illness of Professor Brouardel —One of the general addresses announced for delivery was that on the "Struggle against Epidemics," by Dr. Brouardel, of Paris. The speaker was prevented by illness from attending, and his place was taken by Dr. Bouchard, who read an address on "Fever."

The Polyclinic, where the section meetings were held, is situated most inconveniently outside the walls, at a long distance from the centre of the city. The roads leading to it were only completed after the Congress

work had begun. The extra omnibus service promised by the committee was conspicuous by its absence, and the only way to reach the building was by cabs, the distance from the street car terminus being too great and the road too rough to make walking feasible for any but athletes. Nevertheless, cabs were hard to get, and many had to trudge through mud or dust, as the weather happened to be.

The Most Gorgeous Man in Rome was one of the professors of the University of Coimbra, in Portugal, who wore over his shoulders a sort of cape of bright yellow silk, and on his head carried a hat of the same material, shaped somewhat like a small tiara, covered with tassels.

The Most Popular Exhibit in the Hygienic Exposition was that of the Münchner Bürgerbräu. It consisted simply of a bar covered with half-litre mugs and a beer barrel, behind which stood two Bavarian maidens, clothed, the one in blue, the other in red, who dispensed the hygienic liquid to a line of thirsty congressists.

The Medico-hygienic Exposition was opened without any special ceremonies on March 28th. It was held in the Palace of Fine Arts built to exhibit the pictures of modern Italian artists. A large concourse was present, including the officers of the Congress, Signor Crispi, and many other local celebrities. The exhibition was of the usual order: books, mineral waters, drugs, surgical instruments, microscopes, malto-coffee, beer, plans of hospitals and cemeteries, a description of the works undertaken for the sanitation of Rome, etc. It was not as complete or as interesting as the one held in Berlin during the tenth International Congress.

The Costanzi Theatre, a very large building, was packed to suffocation during the opening ceremonies. The doors were opened at nine o'clock, and by half-past nine it was almost impossible to get in. The parquet was boarded over and was filled with members standing, the three balconies being reserved for the ladies, foreign ambassadors, and other distinguished personages. The king occupied a throne on the stage, and beside him sat the queen and members of the royal household.

Rome was never so crowded as during the Congress week, for in addition to the thousands of physicians and ladies accompanying them, there was the usual throng of Easter visitors. Every hotel and boarding-house was packed, and furnished apartments in all parts of the city were at a premium.

The Teatro Costanzi, in which the inauguration exercises were held, will recall to former visitors in Rome the hotel of the same name which was patronized extensively by Americans. Signor Costanzi, the proprietor of the hotel, made a fortune out of it, and wishing to perpetuate his name, built this theatre. It cost half a million and nearly ruined him, but he felt amply repaid for the outlay on the opening night when he was knighted by the king.

The Ladies of the Congress wore as a distinguishing badge a daisy, the flower being chosen in honor of Queen Margherita.

Rome is behind the times in many respects, like many other European cities, in American eyes, but it has the merit of immaculately clean streets. They are cleaned on the block system, and men are seen everywhere, in the poorest parts of the city as well as in the principal thoroughfares, constantly sweeping up the refuse and depositing it in baskets, whence it is removed at frequent intervals in tightly covered hand carts.

The Gala Representation at the Costanzi Theatre, given in honor of the Congress on Friday evening, was a performance of Verdi's "Traviata." The price of seats was put at $6, yet the attendance was good. Rome is not celebrated for its opera, but the performance on this occasion was far from mediocre.

Reception at Naples.—Many of the foreign members paid a visit to Naples at the close of the meeting. The municipal authorities made an appropriation of 3,000 lire for a reception and concert in their honor. Excursions were made thence to Pompeii, Vesuvius, Capri, and other points of interest in the neighborhood.

The Section of Military Medicine and Surgery made an excursion on Sunday, in a special hospital train, to Tivoli. A military concert was given in honor of the visitors upon their arrival, and in the evening the Grotto of the Sirens and the Aniene waterfall were illuminated with Bengal lights. The Temple of Vesta and that of the Sybils were also illuminated with electric lights.

Reception at the Palace of Fine Arts.—On the evening of March 28th, a reception was given in the hall of the Hygienic Exposition. The building is large, but the crowd was larger, and the resulting discomfort was great. Much dissatisfaction was expressed with the arrangements of the reception committee, but unjustly, for it was not the fault of the committee that the building was not spacious enough to accommodate the members that filled it. The number of adherents to the Congress was so much in excess of what was anticipated, almost every gentleman being accompanied by one or more ladies, that it was simply impossible to provide for them. The buffets suffered the most, and an hour after the opening of the reception there was nothing left but flasks of chianti. Several medical students who had recourse to these flasks for want of something more substantial and less exhilarating, were subsequently carried home by the obliging policemen.

The Queen's Linguistic Accomplishments.—After the speaking was over at the inaugural session, the king and queen held an impromptu levee, receiving the presidents of the foreign committees. The queen conversed with the various representatives in English, French, German, and Italian, using each language in turn with perfect ease and fluency, and with a scarcely perceptible accent.

The Press Committee of the Congress was a very uncommunicative body. Bureaus for the lay and medical press were open in the Polyclinic, but beyond a few copies of telegrams from Koch and others who could not come to Rome, there was no information to be obtained. The members of the committee seemed to know nothing, and to be unable to learn anything of what was being done.

Meeting of Americans.—A meeting of members from the United States and Canada was held on Saturday morning in one of the rooms of the Polyclinic, under the presidency of Dr. Jacobi. It was thought that by organizing, the English-speaking members would be able to obtain some information concerning the Congress—information which it was impossible to obtain even by those who had command of the four official languages. A committee was appointed to learn what could be learned, and to communicate it to the members. Some of those present delivered themselves of very emphatic remarks upon the general confusion and the total lack of any facilities for the non-Italian speaking members of the Congress. The remarks were justified, though ineffectual, for the officials themselves were as much at sea as the foreigners, and a more go-as-you-please and never-get-there Congress was probably never held. One of the propositions made at the meeting was that the Americans unite with the English, with whom the suggestion originated, to form a special section where they might read their papers and be listened to with a show, at least, of respect, but this was very properly rejected. It was then decided to form a social organization, and a bureau of information. The bureau of information died from starvation, for no one could learn anything of any event until after the event had taken place.

Among the New and Highly Specialized International Congresses one is announced on "Marine Hydrotherapeutics." It is to be held in Boulogne on July 25.

Brazil.—The rebellion is over, but yellow fever is now to the front. There is a large daily mortality from it in Rio Janeiro.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 15, 1894.

D. B. St. John Roosa, M.D., President, in the Chair.

Greek as the International Language of Physicians and Scholars in General.—Dr. Achilles Rose read the paper. The desirability of having a single international language must have impressed itself upon the minds of all who had attended an international medical congress. Very few of the members at such meetings were able to speak, or even to understand, more than two languages, perhaps only their own, whereas three had been official, and at the next meeting five would be recognized. The advantages to be derived from a single official language had occupied the minds of many thinkers. The best known of later attempts to invent a language was that of Volapük, but the impracticability of this as a language of science had been conceded by those who had given the matter special attention. The rivalry of nations was against the acceptance of any of the three great living languages—German, French, and English—as official, not to mention other objections, particularly their want of richness in combinations. On the other hand, Greek was free from these objections and possessed many positive advantages. True, it was called a dead language, but it was dead only in the minds of college professors. It was spoken to-day by several million people essentially as it was in the times when the classics were composed. Medical terminology, and that of the arts and sciences in general, were already dominated by the Greek language. It was particularly rich in combinations, and was the most beautiful language spoken, its innate superiority accounting for its survival of centuries when the Greeks themselves had suffered all kinds of reverses and been reduced to a handful in numbers. The author estimated the number of those speaking the Greek language to-day at seven millions. Latin, on the other hand, was not a living spoken language, and was kept in existence only through philological and theological literature. The conversational language of a nation was the key to its written language, and the easiest and best way, the most efficient way, was to begin with the language as the people were accustomed to use it in every-day life. According to the present methods of teaching Greek, it would be considered too difficult to learn, and could never become an international language. But this would be true of any language whatever if it were taught as Greek and Latin were taught in our colleges. There was no truth in the statement that the Greek of to day was dominated by the Slavonic or Turkish; nearly everything of foreign origin had been excluded. Specimens of magazines and letter-writing in Greek were exhibited.

The author criticised severely the collegiate method of teaching Greek, which he said originated in 1528, with Erasmus, a crank in this matter. How difficult it would be to gain a knowledge of English by pursuing the same course, starting, for instance, with the poems of Longfellow, parsing every sentence, and pronouncing the words as it might suit the fancy of the teacher. To learn a language one should begin with easy books, children's books, and listen to the conversation of natives. By such a method one would soon be enabled to do away with the dictionary, which at present even scholars required in reading Greek.

A language which gave terms to all new inventions and discoveries, and which could not be replaced by any other, was already, to a certain extent, an international language.

Danger of Disintegration of the International Medical Congress.—Dr. A. Jacobi had been much interested through the enthusiasm of the author for his subject, and in the question of having an official language for the international Medical Congress. At first, German, French, and English had been official, but as the meetings had been held in other countries the language of those countries had one by one been made official, and the result had been that it was impossible to understand more than a few of the many papers and discussions at these meetings. As a rule only Frenchmen listened to papers read in French, Germans to papers read in German, Englishmen to papers read in English, and so on. Unless something were done, he feared that adding more official languages to the list would result in the International Congress becoming split up into a number of national congresses. There were only two ways in which medical men of different nationalities could understand one another. One was to learn the different languages; the other to agree upon and learn one international language. The former was very difficult, for few men had time to learn several languages, especially after they had entered upon the practice of medicine. It was possible, however, where the knowledge of the languages was gained during childhood by the conversational method. What he had learned of Greek was as it had been taught in colleges; he had acquired it with great difficulty and had lost it with great facility. He thought that Dr. Rose's paper might have greater effect if presented before the approaching meeting of the International Medical Congress.

Thinks English will be the International Language.—Dr. C. A. Leale read some remarks. He said that when Dr. Rose had requested him to discuss his paper he expressed the opinion that English was more likely than Greek to become the universal language, and further thought upon the subject had tended to confirm him in that view. Dr. Leale seemed at present not to have much confidence, however, in any language becoming universal, at least not for many years. While many years ago he had been impressed with the prophecies of Miller, and thought that wars might cease, and peace reign universal, yet we found the world had not come to an end, and there continued to be war and rumors of war. So with his youthful ardor regarding the universal brotherhood of man, which he expected to be distinctly American; further observation and travel had led him to the belief that languages, like diseases, varied with the soil and the character of the people who made that soil their home. If it were possible to perform the miracle of bringing all peoples together and giving them an understanding of a common language, without continued education, such a language would not remain universal, the several peoples would relapse into their former customs and employ language orally alone, such as would require the least effort, that which they had been accustomed to from childhood. His reason for regarding the English language as destined to become the universal language, if any could be called such, was the fact that it had spread so widely over the globe, was used by so many more people than the German or French or Greek, and in it were recorded the doings of art, science, and literature throughout the world; its relative increase among the people was shown by the following figures. The population of the earth was estimated as 1,440,650,000. In 1801 the English language was spoken by 12.7 per cent., and in 1890 by 27.7. In 1801 French was spoken by 19.4, and in 1890 by 12 7. The German language, in 1801, by 18 7, and in 1890 by 18.7. English had rapidly increased, while French had actually decreased, and German had remained stationary.

Two Questions.—Dr. W. H. Thomson thought the question naturally assumed two forms: 1. Was an international language at all practicable at a medical congress? 2. If it was, what language should be selected? Regarding the first question he saw no possibility of establishing an international language for medicine or science unless a revolution were effected in our systems of education and there was co-operation among the different educators of the world in bringing about so desirable an end. The law of the evolution of language made it imperative, if such a result was to be accomplished, that the language be learned in such a way that men could think in it.

Afferent and Efferent Language.—Physiologically

considered all language was afferent and efferent. Afferent language came through the eye and ear, efferent language passed out through the organs of speech or in the handwriting. Afferent language was acquired chiefly through the ear, and it was only later in life that we used the eye in reading and writing. Yet the colleges would have us learn Latin and Greek exclusively through the eye, which had the least developed tract connecting it with the centres for expression. Dr. Thomson could speak very feelingly upon this subject, for he had studied Greek under his preceptors diligently for many years, and had translated a number of the classics, yet he had never found it possible to think in that language. He was then set to studying Arabic in the same manner, *i.e.*, by the eye alone, but he soon became convinced that he could never get a practical use of it in that manner, and abandoned the method, and went to live among the Arabs themselves, with the result that, notwithstanding the difficulties besetting that copious language, he could yet, after the lapse of twenty-five years, express himself in it with facility. The same difficulties encountered by himself in the study of Greek and Latin were being encountered to-day by his sons at Harvard, where they continued, as in other colleges, to teach those languages by sight instead of by sound and conversation. German and French were taught at Harvard in the same manner; a fact which had always made him sorry for young men who had to acquire their knowledge of the languages at that institution.

Supposing it possible to introduce an international language for medicine, he agreed with Dr. Rose that Greek was best. He would unhesitatingly choose Greek because of its unparalleled and marvellous structure for expressing ideas, and notably its power to express ideas related to science in the most accurate, the most concise, and clearest manner yet devised by man. In this regard it was as perfect as English was deficient in power to express relation between things. Greek showed matchless value.

Dr. Thomson did not take quite so dark a view as had been expressed of the possibility of some one language becoming universal for science, for social and political causes had at different periods exerted marked influence in this direction. French, for instance, was the language of polite scholars and diplomats the last century. If the need of an international scientific language should come to be strongly impressed upon nations, they might agree upon one and put it into practical use by teaching it in the primary schools. While not regarding it as a chimerical or impractical proposition, yet he had not much hope of its being carried out.

English the Language of the Future.—Dr. S. S. Burt acknowledged that Greek was a beautiful and desirable language, but his judgment told him that English was destined to be the dominant language, for the reason that the English people were becoming the dominant race. He did not believe any language would be agreed upon except it were that of the people who were in the ascendency, in whose speech affairs of government were transacted, and science, art, and literature were recorded.

New York without Influence at Harvard.—The President, Dr. Roosa, spoke very feelingly upon the collegiate way of teaching languages. He had devoted a great deal of time to Latin and Greek, and, like the other gentlemen who had spoken, felt that what he knew to day was very little indeed. He started to study German in the same manner, and after some time found himself in Bremen unable even to make known his wishes as to a hotel. There he entered a German family where not a word of English was spoken, had no English acquaintances, and the result was that in two months' time he could go about all Germany and make his wants known without difficulty.

If we were to have an international language, it could only be, as Dr. Thomson had said, by a revolution of teaching methods, and Dr. Roosa despaired of such a revolution because the hide-bound notions of college professors were simply beyond any ordinary assault; for a man from New York to talk to men from Cambridge or New Haven as to ways of teaching would be very much as if he should go to the tomb of the prophet with his boots on.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

PRESIDENCY OF COLLEGE OF PHYSICIANS—MEETING OF FELLOWS OF COLLEGE OF SURGEONS—SUBSEQUENT MEETING OF MEMBERS—THE GRESHAM UNIVERSITY SCHEME—CONVOCATION OF THE LONDON UNIVERSITY WILL OPPOSE—ANOTHER NEW SOCIETY—ONE OF FELLOWS OF THE SURGICAL COLLEGE—AIMS OF THESE AND OF GRADUATES ENTIRELY EXCLUSIVE—RESULTS OF EXCISION OF DISLOCATED CARTILAGES.

London, March 24, 1894.

On Monday, at the Royal College of Physicians, Dr. Russell Reynolds was re-elected President. Since his election to succeed Sir Andrew Clark, until the official year had expired, he had given so much satisfaction that his re election may be called unanimous; for on the ballot being taken eighty-seven votes were cast for him out of the eighty-nine Fellows present. This is as it should be, for it is generally recognized that Dr. Reynolds well deserves the honor conferred upon him.

On Monday also the Fellows of the Royal College of Surgeons met in response to the summons of the council to consider the scheme of the Gresham University Commission. There were between sixty and seventy Fellows present, and the scheme was "cordially approved in principle," as it has already been by the sister college. No wonder, for in it these colleges will rather gain than lose and the Fellows will retain all they have, and the members still be left without representation or influence.

On the next day, Tuesday, the members of the college were allowed to meet in the building of the corporation, the council having given notice of this concession by an advertisement. Accordingly, at the hour announced, four councillors had arrived, and later they were reinforced by two others. There were also three members in the theatre, and this audience swelled to eight before the proceedings were concluded. The resolution submitted, as no one said no, was declared by the president to be carried, and will, no doubt, be duly quoted as strengthening the hands of the council. This quiet assemblage of half a dozen members is all that comes of having extorted the right of meeting. Could the officials who vainly resisted meetings of hundreds have foreseen how little they need fear such meetings they would, perhaps, have desisted from opposition and blandly said, pray, meet in your own college as often as you like, only give us reasonable notice to prepare to receive you with due honor. It has been suggested that the smallness of the meeting is the result of its not being properly advertised. I am rather inclined to attribute it to the conviction of the members that attendance would be utterly futile. Why should they care for any particular scheme for a new university? All they want is a possibility of becoming graduates, and if they could have that what need they trouble about the position of their college, which ignores their existence from the day on which it takes their money?

Although the two colleges so far support the Gresham scheme there will be opposition in other quarters. Already the graduates of the present London University are giving tongue, and the annual Committee of Convocation has formulated resolutions which will be submitted to that body at a special meeting on April 10th. Convocation consists of graduates; it will be remembered that they rejected a new charter proposed to them, and the present scheme, which would certainly injure them, can scarcely expect more consideration at their

hands. The graduates are proud of their degree and desire to maintain its prestige. Naturally enough; but still they might take into consideration broader views of the position instead of always crying out that change will lower the value of their degrees and so rob them of their hard won distinctions. To outsiders their case is much like that of the Fellows of the two colleges who have so "cordially approved" the scheme—that is, it is a case of selfishness all round. The graduates want the standard to be rather raised than lowered so as to make their degrees fewer. The Fellows scream for their "privileges" in their corporations; that is, they want to ignore the members whose money has enabled them to exist. It is a miserable exhibition of the lowest qualities of human nature evidenced by men in possession of both education and money, and dominated with the determination to keep these distinctions to themselves as far as possible.

As if to fill up a busy week, so far as these medico-political questions are concerned, a circular has been issued announcing the formation of a new society of Fellows of the College of Surgeons. Of course the Association of Fellows, which has existed for the last ten years, cannot see the necessity of this, and some very disagreeable insinuations are obtaining circulation. The one thing that may interest outsiders is that both these organizations concern only the two or three hundred Fellows, and will doubtless treat the claims of the thousands of members with contempt. Why, then, should the latter, or, more still, the thirty-one thousand registered practitioners, care about the internecine disputes among the Fellows, the chief concern of both parties alike being the keeping and extending of their privileges?

At the last meeting of the Clinical Society, in addition to the papers I mentioned last week, an account of the result of a case of excision of part of a dislocated internal semilunar cartilage, twenty-one months after operation, was given by Mr. Lockwood, who considered there is rather a dearth of information as to the results of such cases, of which many have been done. Information as to the result nearly two years after the operation was given in the present instance. The patient was an engineer by profession, who injured the knee at foot-ball. Nothing could be felt, but the joint was apt to lock under circumstances which entailed danger to the patient's life. Pain was felt on pressure over the internal semilunar fibro-cartilage, which also seemed too movable, and had probably been injured. The joint was opened by incision vertically, and the anterior third of the internal semilunar fibro-cartilage was found to have been torn from all its tibial attachments. It was removed, and the operation was followed by a slight attack of synovitis, but the patient was up at the end of a fortnight; a month later he walked thirteen miles. Subsequently, after foot-ball he had an attack of synovitis, but no locking; indeed, the joint has not, he said, locked since the operation, and is perfect for wrestling, running, swimming, or bicycling. He is afraid, however, to play tennis or foot-ball, because he fears a sudden twist.

Mr. Croft recalled that he had read a paper on this subject in 1888, in which he had recorded the first case of deliberate removal of the internal semilunar cartilage. Mr. Lockwood, in reply, said that if only slightly detached, it might safely be sutured to the tibia, but if much damaged, it ought to be removed. At the same time he would not like to remove it unless injured.

Dr. Cayley and Mr. Bland Sutton related the case of a man of twenty-five, with perforation of the bowel in typhoid fever, treated by washing out the peritoneal cavity and excising the perforation. The operation lasted nearly an hour, a considerable portion of which time was occupied in washing out the peritoneum. The patient was much collapsed, but gradually rallied and lived till the sixth day, ultimately passing into a typhoid state, with great prostration and rambling delirium. Some leakage of gas took place, and consequently the central stitch of the abdominal incision was removed to allow a free vent. The escape of gas was due to the sloughing of a stitch exactly in the middle of the suture. The perforation was situated twelve inches above the ileo-cæcal valve. The shock of the prolonged operation no doubt diminished the patient's chances of rallying, and in any future attempt it would probably be better not to excise and suture the ulcer, but after washing out the peritoneal cavity to attach the perforated bowel to the abdominal incision and leave a fistula to be dealt with subsequently. Other cases were mentioned, all fatal. Mr. Bland Sutton pointed out that the operation ought only to be attempted under very favorable circumstances, and Dr. Burney Yeo pointed out that had the patient recovered there would probably have resulted stricture of the gut where sutured.

Dr. Cayley admitted that patients might sometimes recover after perforation, but not if there was much extravasation.

LETTER FROM ROME.

(From our Special Correspondent.)

THE MEDICO HYGIENIC EXHIBITION—A CROWDED RECEPTION—INAUGURAL CEREMONIES—ADDRESSES OF WELCOME—SECTION MEETINGS AT THE POLYCLINIC—FIRST GENERAL SESSION—ADDRESSES BY VIRCHOW AND BOUCHARD—LA TRAVIATA—NUMBER OF MEMBERS.

Rome, March 31, 1894.

The ceremonies of the Congress proper were preceded, as usual, by the opening of the Medico hygienic Exhibition, which has now become a regular institution in connection with all important medical meetings in every part of the world. This exposition was under the special direction of Professor Pagliani, Treasurer of the Congress, and Director-general of Public Health under the Italian Government It was very similar to the drug exhibits, so familiar to all who are in the habit of attending the meetings of the American Medical Association, though naturally on a larger scale, and embracing certain features not seen there. These latter may be described as of the non-commercial order, consisting in models of hospitals, both civil and military, cemeteries, crematories, appliances for public sanitation, a description, accompanied by photographs and designs, of the works recently undertaken by Professor Pagliani's Bureau for improving the health of Rome, and the like. The exhibit was one that reflected credit upon the organizers, but truth compels the admission that it did not compare favorably with the one in Berlin, in connection with the Tenth International Congress in the summer of 1890.

On the evening of the same day a reception to the members of the Congress and their wives was given in the Palace of Fine Arts, where this exhibition was held. The crowd present exceeded every expectation of the managers, and the result was a perfect jam—ladies' dresses were torn, men's hats were crushed, and the heat was asphyxiating. The provision of refreshments at the various buffets was quickly exhausted, the only thing left being wine. A number of the younger guests were driven in their desperation to partake of this too freely and had to be carried out of the building by the attentive *carabinieri*.

Thursday, the opening day of the Congress, was a perfect spring day, with bright warm sun and not a cloud in the sky. It was announced that the doors of the Constanzi Theatre, in which the inaugural exercises were to be held, would be opened at 9 o'clock and closed at 10, after which time no more would be admitted. A perfectly useless precaution, for by 9.30 the building was so packed that not a mouse could have squeezed his way in. The invitations were not confined to members of the Congress, of whom there were nearly seven thousand, not counting their wives and daughters, but tickets were sent to members of the diplomatic corps, the Italian senators, deputies, and other officials, with their families, and generally to all the leading citizens of Rome belonging to the Royal faction. The theatre is an

immense structure, but it could not hold such a crowd, and many members of the Congress, attired in the dress suit which is *de rigueur* at all functions on the Continent, even before breakfast, were unable to gain admittance.

The arrangements within the theatre for seeing and hearing were as bad as they could possibly be. The king's throne was placed at the back part of a very deep stage, and the addresses were all delivered from the same place. The result of this was that many, even those in the best boxes, could not see their majesties and the speakers, and those in other parts of the building could hear not a word. However, the toilets of the women were pretty, the queen was, as always, charming, and those who were fortunate enough to get into the theatre seemed to be fairly satisfied.

The king and queen arrived half an hour late, and immediately after they had taken their places, Signor Crispi, the Prime Minister of Italy, began his address. After the applause which broke out at its conclusion had ceased, Dr. Baccelli stepped forward and spoke for a few minutes in Latin. It was interesting to note the close relationship between this language and that of modern Italy when the former is spoken with the Italian intonation. It was quite evident that those who stood within hearing distance of the speaker were able to follow his words and grasp their meaning, which would not have been the case with an audience of any other nationality. Then Prince Ruspoli, the Mayor of Rome, extended a welcome to the assembled members in the name of the city, recalling the fact that physicians had always been held in high esteem in Rome from its earliest days. After this Professor Virchow was called upon, in his capacity as President of the Berlin Congress, to address the members. In compliment to his hosts he spoke in Italian, and was roundly applauded when he sat down. Professor Maragliano, the secretary, then read the report of the Organization Committee and presented the figures of attendance at former congresses, showing that the present one exceeded the most largely attended of any of the preceding by at least 2,000. The presidents of the foreign committees were then called upon in turn, but after some eight or ten had spoken the king showed signs of weariness and this part of the programme was abruptly cut short.

Dr. Virchow then moved that the present officers of the Congress be elected permanent officers for the Rome meeting, and the motion was carried by acclamation. The meeting was then declared adjourned. Their majesties remained on the stage a few moments conversing with the chairmen of the foreign delegations, and then passed out, being followed by the entire throng of natives and foreigners anxious to see them enter their carriage and drive away.

In the afternoon the nineteen sections met for organization and election of officers at the Polyclinic, and then was made very evident the inconvenience of this locality for the meetings. It is true that the sections are all located in what is practically one building, but this building is at such a distance from the centre of the city that it can be reached only by cabs. The terminus of the street-car line is a good three-fourths of a mile away, and the extra line of omnibuses promised by the managers of the Congress was nowhere visible. It was comparatively a simple matter to find a cab in the city and drive to the Polyclinic, but the return was not so easy. The few carriages at the door of the building were taken by the first comers, and the others had to walk to the station of the street-cars, there to find that the cars, running only every fifteen minutes and accommodating only twenty persons each, were full. Then followed a weary trudge from the city gate home. This experience was repeated yesterday and to-day, and will doubtless be to the end of the meeting.

At the Polyclinic policemen and special officials are posted everywhere, but they might as well be absent as far as the convenience of the members is concerned. They talk nothing but Italian, and can give little or no information even when addressed by their own countrymen. There are rooms for all the national committees in which men are supposed to be stationed permanently to give information to any inquirers. A visit to all these rooms was made on the opening day, and all were empty except the English room. In that one an Italian was found who spoke his own language and a few words of French, but English was a tongue that he had never attempted to master.

On Friday afternoon the first general session was held in the Eldorado Amphitheatre. This is a small wooden building, capable of holding about five hundred people, and several thousand tried to get into it. They naturally did not succeed, but their efforts drowned the voices of the speakers so that they were inaudible to all except those in the front rows of seats. There were no opening ceremonies, but as soon as the president had taken his seat Professor Virchow advanced to the front of the stage and read his address on Morgagni. It was delivered in German, and was very long, a full hour being consumed in its delivery. At its termination Dr. Casati di Forli, in the name of his city, in which Morgagni was born, presented the speaker with a medal. The second address was by Dr. Bouchard, of Paris, who took the place of Dr. Brouardel, the regular appointee, who was prevented by illness from attending. The subject of the address was "Fever." Then Dr. Babes, of Bucharest, read his address on "The State in its Relation to the Results of Modern Bacteriological Research."

In the evening a representation of "La Traviata" was given at the Costanzi Theatre, in honor of the Congress, but for which those who were present had to pay from 36 lire a seat to 200 lire a box. A very large number of the members did not attend. The performance was good enough, but not extraordinary. Rome is not celebrated for the excellence of its opera, and this so-called gala-evening added nothing to the reputation of the city in this respect.

The number of members registered up to the present writing is 7,612, of whom about one-half are Italians, one-quarter Germans and Austrians, the balance being pretty equally divided among the other nations of Europe. America—North, Central, and South—is represented by less than two hundred, the greatest number from any one country of the Western Hemisphere being from Mexico, which has quite a good showing. The faults of the Congress are due entirely to its size. Rome made preparations for some three or four thousand guests, and it has double the number, and does not know what to do with them. At all the meetings and receptions thus far the members have been packed together like sheep in a pen, and many (the more fortunate) have been unable to get into the buildings at all. The scientific work promises to be good, though there are not likely to be any such startling announcements made as that of Koch at the Berlin Congress. Four thousand papers are announced as to be read, but many of these will, of course, be read only by title.

A Hospital Train.—The Italian Central Committee of the Red Cross prepared for exhibition a hospital train, consisting of twelve communicating cars fitted up with beds, appliances for the sick and wounded, medicine and instrument chests, cooking apparatus, lavatories, quarters for the surgeons and nurses, etc. The train was side-tracked near the railway station, and was inspected with much interest by numbers of the visitors.

The Mayor's Proclamation. — Prince Ruspoli, the mayor of the city, issued a proclamation the day before the opening of the Congress, of which the following was the closing paragraph: "Citizens! The municipal authorities, interpreters of your sentiments, extends an affectionate greeting to our illustrious guests, and invites you to receive them joyfully. May the ancient motto, '*Roma communis patria*' remain with them forever, thanks to your friendly reception, an agreeable remembrance."

A Theft of Tickets.—Several packets of the special

cards of invitation to the lunch at the Baths of Caracalla were abstracted by somebody the first day of the session. The first issue was therefore cancelled, and new cards were printed. Many members who had received the original tickets did not know of the change, and were grievously disappointed on presenting them at the entrance to learn that they were worthless.

Visit to the Military Hospital.—On Thursday, at four o'clock, the foreign military surgeons attended a reception given in their honor at the new Military Hospital on the Cœlian Hill. The visitors were entertained at lunch, and then shown through the wards of the hospital, which is held, after the Hamburg Hospital, to be one of the best appointed in the world.

Baccelli's Address.—The following is the text of the address in Latin delivered by Dr. Baccelli at the inaugural ceremonies:

Postquam Italia universa in unum corpus iterum coaluit et sui juris fuit, præclaris benevolentiæ atque honoris testimoniis idemtidem gaudet, vel in maximis difficultatibus quae novam exordientis vitæ civilis rationem necessario comitantur.

Anno superiore, in festis genuensibus, totius pene orbis gentes loricatas naves miserunt, quae Cristophorum Columbum, italicum civem, merito honore decorarent. Hodie viros Romam mittunt biologicae doctrinae peritissimos ut vincula arctius constringant, quae communis utilitatis causa nos jungunt. Hi Romam petunt, fortasse non immemores, spectatissimos olim cives politica medicina animum excoluisse, quam antiqui reipublicae rectores tanquam nobilisimam virtutem exoptarent: de quo Tullius et Cato abunde testantur.

Salvete igitur, clarissimi viri!

Classica haec regio libens Vos excipit ubi divinus libertatis halitus veterem gentis magnitudinem reducet. Hic nemo habetur extraneus. Hic ubi omnis terrae pars sua monumenta invenit, omne hominum genus unam tantummodo familiam constituat. Unusquisque consilio et opere, populorum incolumitati, hominumque valetudini prospiciat. Tunc memorabiles patrum latinorum sententiae per Vos novissima luce nitebunt "Salus populi suprema lex esto" et "nulla re magis homines ad Deos accedere quam salutem hominibus dando."

Hospites doctissimi, iterumque iterumque salvete!

Humbertus et Margarita, regiae virtutis exemplaria, honoris causa vobis intersunt.

Hic adstant supremi rerum italicarum moderatores; adstant qui vice funguntur Senatus et Oratorum popularium legibus ferendis; adstant Municipiorum curatores; tota civitas conspectu vestro gaudet et vobis plaudit. Ego vero singulari laetitie perfundor quod Regis voluntate ac nomine mihi liceat dicere—Undecimum omnium gentium de medicina conventum, hodie, Roma auspicatur.

ELIMINATIVE TREATMENT OF TYPHOID FEVER.

To the Editor of the Medical Record.

Sir: The communication of Dr. William Osler, of Baltimore, in your journal of March 31, 1894, concerning the purgative treatment of typhoid fever is of interest to me from the fact that I have recently set forth the results of sixty cases of this disease[1] treated according to this method. While my plan has varied somewhat in detail from the one advocated by Dr. Thistle in the Medical Record under the date of March 10, 1894, still the principles involved are the same in both, the treatment being essentially purgative in character. With respect to the history of this method or as to who first advocated its usefulness, it matters little, since the credit belongs not to the mere discoverer, but to those who, having once found and demonstrated its merits, earnestly and persistently set forth its claims and forced the profession to notice and to heed. Dr. De Laroque, physician to the Necker Hospital, Paris, may have successfully employed purgatives in typhoid fever, but it remained for Dr. Thistle and others to rediscover and use them intelligently or rationally and point out their true sphere and modus.

CHLOROFORM NARCOSIS—SHOULD IT BE TREATED BY THE APPLICATION OF ELECTRICITY?

To the Editor of the Medical Record.

Sir: My attention has only to day been called to Dr. J. H. Blanks's very interesting comments, in the Medical Record of March 31st, on my article about chloroform narcosis, etc. The question as to whether electricity should or should not be applied in chloroform narcosis is one of much practical importance, and cannot be decided by theoretical considerations alone, however rational. Basing one's ideas alone on the physiological action of the pneumogastric, and the effects of a current when applied directly to it, it becomes seemingly apparent that electricity can exercise no possible function either directly or indirectly as a heart-stimulant.

Looking at the subject, however, from another standpoint — the standpoint of the cardiac excito motor branches of the sympathetic that are generally supposed to convey influences which accelerate the heart's action —an argument is readily found for the other side of the question.

In addition to these cardiac-stimulating branches, there are also certain stimulating cardiac fibres arising in the brain that pass to the inferior cervical ganglion, and thence to the tissues of the heart. We have all heard of the so called "pressor" nerves of the cervical sympathetic and the vagus, irritation of which, physiologists tell us, increases "tone reflexively," acting in opposition to the ramus depressor of the vagus, and it is a matter of record that through irritation of the ganglion stellatum and the upper thoracic ganglion connected with it the heart may be made to act more rapidly or may be set in motion again after it has ceased to beat.

But these theoretical considerations in favor of the utility of electricity in chloroform narcosis, as well as those against it, so clearly presentend by Dr. Blanks, weigh very little with me as compared to the records of experience in the treatment of a number of cases of threatening death from both opium and chloroform poisoning. Of one thing I am quite certain, and that is that any ordinary percutaneous application of the induced current of electricity has very little if any influence on the heart's action, while the same strength of current, as can be readily demonstrated, may be made to very positively influence the respiration. Dr. Blanks is of the opinion that a strong induced current applied in the neighborhood of the pneumogastric during chloroform narcosis is dangerous. Of course the word "strong" is a relative term and we cannot discuss this. I can only repeat that my experience is the reverse of this, and reassert the salient point of my first communication, that "electricity does good in increasing respiratory activity, the strength of current for this purpose being insufficient to materially interfere with the movements of the heart, through its action on the inhibitory fibres of the pneumogastric that control it."

Intravenous Injections of Corrosive Sublimate.—Dr. Guido Bacelli recommends the direct injection of a sublimate solution into the veins for the cure of syphilis. He uses a mixture consisting of hydrarg. bichlorid., 1 gramme: natrii chlorid., 3 grammes; aquæ destil., 1,000 grammes. Of this he injects 1 ccm. daily, increasing the dose to 2, 3, 4, and even 8 ccm. The results are said to be rapid and brilliant.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending April 14, 1894.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	5	5
Scarlet fever	151	20
Cerebro-spinal meningitis	1	9
Measles	299	16
Diphtheria	180	41
Small-pox	21	7
Cholera	0	0
Varicella	0	0
Pertussis	0	0
Erysipelas	0	0
Leprosy	0	0

Accounting for Gout.—If we are really to take human nature exactly as we find it and provide respectfully for its manifold demands Heaven help our descendants! The imperious natures of our grandfathers called out for wine in such liberal quantities that they ended their repasts under the table. Thence the imperious nature of our gout. Truly a more insane mistake than that of consulting the mass of evil habits, even heredity, evil instincts which flourish in that rich soil which our social system has provided for so many centuries, is hard to conceive; yet the practical person enjoys the credit of calm and mature judgment who assures us that in all these matters the nature of man must be our guide. It is in vain to oppose it. One forgets that just as such an individual can found a robust dynasty of tyrants in his body and his soul, so can an entire race enthrall itself; in which case, however, be it observed, the demoniac possession will not be regarded as disease, but as a normal state, which indeed it is, but not the healthy or the necessary one. The practical person is opposed to revolutions, even when directed against the tyranny of evil habits. When such habits engender gout and rheumatism and consumption and heart disease, the sufferers have to bear their pains, for they have not yet found the means to thrust these things directly on to other shoulders. But when the folly and wickedness that circulate in the blood, bequeathed by the sins of ancestors, break forth in the form of fierce passions, then their force may be expended to the injury of other human beings who are plentifully provided by the foresight of society as its scapegoats. All pain and trouble thus are spared—for the moment—to the heir of the ages. He settles his account later on.—*Westminster Review.*

Parasitic Anæmia and Diarrhœa.—Professor Penberthy, of the Royal Veterinary College, has described a small nematode which he regards as the cause of anæmia and diarrhœa in cattle. The small strongyle is found in the mucous membrane of the abomasum and small intestines, free and partially imbedded under the epithelium. It is not usually detected by the naked eye, but a light scraping of the mucous membrane placed under a $\frac{1}{4}$-inch objective allows of differentiation of the sexes, and sometimes a field reveals as many as six worms. The length of male and female may be roughly stated at from $\frac{3}{25}$-inch to $\frac{6}{25}$-inch. The female, pointed at each extremity, usually contains relatively large ova. The male is provided with a bilobed bursa supported by eleven rays, four on each side and three centrally placed more distinct and the middle bifid at the free extremity; above the bursa is a retracted spicule, dark and prominent. Another female parasite found in very acute and fatal cases is about $\frac{8}{25}$ inch in length, very fine, and pointed at each end. This the author regarded as *Anguillula intestinalis*, which is credited with inducing anæmia in various species of animals. Young cattle are most commonly affected, and often the losses are very serious. The symptoms are those of anæmia and diarrhœa, the course, according to the number of parasites, acute or chronic, and the result often fatal. The parasite has been demonstrated in cases heretofore attributed to tuberculosis, sewage poisoning, etc. It is stated that if the anæmia is not very far advanced the disease yields to such remedies as asafœtida, turpentine,

The Value of Initials.—According to a writer in the *Glasgow Evening News*, three doctors carry on their business in one outlying district of Glasgow, each of them happily self-conscious that he is a better man than his neighbor, with a result that more than the ordinary degree of professional jealousy exists. The secretary of the Free Breakfast Fund called on No. 1 recently and solicited a subscription, which was readily given, the donor adding to his signature the letters M.B., C.M. No. 2, across the street, was next waited upon, and he likewise put his name down, with the affix M.B., C.M., L.F.P.S.E. Next No. 3 was asked to subscribe, and entered his name on the list with the addition of the letters L.R.C.P.Edin., L.R.C.S.Edin., L.F.P.S.Glasgow, L.M. Last of all the subscription sheet reached a worthy in the district who put down his name, and, not having any degrees to brag of, he added, "A.B.C.D.E.F.G.H. I.J.K.L.M.N.O.P.Q." When asked what it meant, he replied that it meant nothing, but that he had given a shilling more than any of the doctors and he considered himself on that account entitled to the most space for letters!

A Charitable Angel without a Trumpet.—A member of the faculty of one of the hospitals whose duty it is to collect funds for the payment of arrearages made a bold stroke for a large contribution from one of his friends—a business man and millionaire—by prudently asking through telephone for $5,000. To his great joy an affirmative answer was sent, with the condition that the source of the supply should be known to no one but the receiver. But now numerous impecunious charities are curiously anxious to give him like opportunities for quiet benefactions.

Sea Air and Mountain Air.—Sea air and mountain air, both being tonic, will probably improve the health that is already fairly good. Children almost invariably

do well at the sea side, while mountain resorts are in general much less suitable for them. The same rule applies, though for different reasons, to the aged. Dyspepsia, especially if of hepatic origin, often does badly at the sea side, but well in the mountains. Skin diseases, especially eczema, are often aggravated by sea air. It is not clear that mountain air has any effect upon them. [illegible] does notably better at

has introduced a very delicate test for minute traces of albumin in urine. He states that by its means he can detect 1 part of albumin in 225,000 parts of urine. The test solution is composed as follows: Hyd. perchlor., 8 grammes; acid. tartaric., 4 grammes; sugar, 20 grammes; distilled water, 200 grammes. The sugar serves to raise the specific gravity of the liquid to 1060, which is higher than that of nearly all urines. It is used by placing some in a test-tube and gently adding a little of the urine to be tested. If albumin is present a ring will form at the junction of the two liquids. Dr. Gurrieri has made some observations on this reaction, and has ascertained the fact that the reaction is incapable of detecting even large quantities of either egg- or serum albumin, save in the presence of chlorides or hydrochloric acid, the reaction being more marked in proportion to the amount of chlorides present. The same is true for albuminous urine if the chlorides are removed by previous addition of silver nitrate, and subsequent removal of the silver salt. In the rare cases, therefore, in which urine is free from chlorides, the reaction as it stands will not take place, and it would be necessary to add a trace of chloride. A minute quantity of urine, added to a solution of pure albumin of any kind, was found to be sufficient to ensure the success of the test, by virtue of the chlorides contained in it. In order, therefore, to make the original test unfailing the author suggests that it would be as well to add a small amount of chloride to the test solution, which then becomes an exceedingly useful one for clinical purposes.—*The British Medical Journal.*

The Quarantine Bill of the Academy of Medicine is being pushed at Washington, and we hope it may pass. The MEDICAL RECORD recommends it in an exceedingly well-timed and well-written leading article, in which the merits of this thoroughly considered bill are carefully gone over. The bill is so perfect and will make so good a law that we fear it may not pass, but we hope for the best. Certainly it is about time that our country paid some official attention to its national health, as well as to the tariff.—*The Post-Graduate.*

A Medical General.—Dr. Carronge, Colonel of the 139th Regiment of Infantry, has been promoted to the grade of General of Brigade.—*L'Union Médicale.*

Vaccination in the French Army.—A correspondent of *Le Progrès Médical* recounts a curious method adopted by French soldiers to prevent vaccination being successful.

"I was talking this morning," says the writer, "to a soldier on furlough about the way vaccination was performed on recruits when they joined their regiments. My interlocutor informed me that last year, in his company, not a single case had been effectual. On my expressing surprise at such a result, he triumphantly disclosed the secret of the failure. An old soldier had 'put them up to a dodge' whereby they would be able to avoid the discomfort inseparable from the evolution of a vaccinal vesicle. Each little incision was immediately sucked by a friendly comrade as soon as the doctor's back was turned."

In addition to falsifying statistics, such a procedure might be attended by most serious personal consequences.

Thiersch's Method of Skin Transplantation.—Schnitzler and Ewald (*Centralbl. für Chirurgie*, No. 7, 1894) assert that they have been thoroughly convinced by a number of observations in Albert's clinic that large skin grafts formed by Thiersch's method become fixed and grow just as readily on granulating as on raw surfaces. By applying the grafts directly to a granulating surface and by not scraping away the granulations much pain and bleeding are prevented. The authors attach no importance to the necessary neglect of antisepsis in Albert's method, and cite a case of large open surface near the mouth which was successfully closed by transplantation without any attempt having been made to protect the parts from infection. As the more painful stage of Thiersch's method—that of scraping away the granulations—is omitted, it is not necessary to administer a general anæsthetic. Before cutting away the large grafts the skin is frozen by ethyl chloride. The frozen skin, in consequence of its hardness and freedom from elasticity, can be cut more readily. The sections thus made are, however, somewhat thicker than those obtained from unaltered skin. By this modification all the advantages of Thiersch's method may be obtained, and the transplanted grafts adhere and grow more readily, and are more permanent than those formed after Reverdin's method.

The Pneumatic Cabinet in Phthisis.—Dr. Charles E. Quimby believes, as a result of six years' experience (*International Medical Magazine*) with the pneumatic cabinet, "that from seventy-five to eighty per cent. of localized tuberculosis, if seen reasonably early in the first stage, can be brought to and kept in a condition of practical cure by the use of the pneumatic cabinet and adjuvant measures other than climate; that cases of disseminated tuberculosis will be arrested in about fifty per cent. of cases, but will require treatment for long periods; that subacute cases may be arrested and made quiescent, when seen first in the second stage, in possibly fifteen per cent. of cases; that third-stage cases, if chronic, are always relieved in their rational symptoms and their downward course made easier; while those following acute consolidation are benefited but little, if any, and without care may be made worse. Bronchial hemorrhages are arrested almost without exception, and frequently do not return, even when the cases progress unfavorably. With rare exceptions all the subjective symptoms are relieved, even when the phthisis is not arrested."

Professor Rubner has been chosen to succeed the late Professor August Hirsch in the Chair of the History of Medicine in the University of Berlin.

DIGESTIVE PROTEOLYSIS.

THE CARTWRIGHT LECTURES FOR 1894.

BY R. H. CHITTENDEN, PH.D.,

PROFESSOR OF PHYSIOLOGICAL CHEMISTRY IN YALE UNIVERSITY.

(Continued from page 487.)

LECTURE II.

PART II.—PROTEOLYSIS BY PEPSIN-HYDROCHLORIC ACID.

ON the assumption that these various products of proteolysis are formed by a series of hydrolytic changes, accompanied by cleavage of the molecule, we might at first glance look for a marked increase in the content of hydrogen. But when we consider the size of the proteid molecule, with the small proportion of hydrogen contained therein and the large amount of carbon, it is plain that hydrolytic cleavage might naturally leave its mark on the percentage of carbon, rather than on the percentage of hydrogen of the resultant products. In view of these facts, the above results show nothing inconsistent with the theory that pepsin-proteolysis, as a rule, is accompanied by a series of progressive hydrolytic cleavages in which the primary proteoses are the result of a slight hydration, these bodies by continued proteolysis being further hydrated with formation of secondary proteoses, which in turn undergo final hydration and cleavage into true peptones. In accord with this theory, true peptones always show a marked difference in composition from that of the mother proteid, the most striking feature being the greatly diminished content of carbon, which may be taken as a measure, in part at least, of the extent of the hydrolytic change. And it is to be noticed that the crystallized phytovitellins are no exception to the general rule; the secondary vitelloses and peptones resulting from proteolysis bear essentially the same relationship to the mother proteids that the albumoses from egg-albumin do. Moreover, the alcohol-soluble proteids, of which the zein of cornmeal is a good example, show the same general tendency, and it is an interesting fact that the proteoses, or more specifically the zeoses, formed from this peculiar proteid, are readily soluble in water and show the general proteose reactions. It may also be mentioned that these zeoses, as well as the elastoses, are very resistant to further hydrolysis by pepsin-acid, and yield only comparatively small amounts of true peptones.

In connection with the question of the composition of proteoses and peptones as formed by pepsin-proteolysis, it is interesting to note a recent observation recorded by Schützenberger.[1] This experimenter took 350 grammes of moist blood-fibrin, corresponding to 75.5 grammes of dry substance, and subjected it to proteolysis with 2.5 litres of a very strong pepsin-hydrochloric acid solution for five days. The resultant fluid was then freed from acid by treatment with silver oxide, after which the solution was evaporated to dryness on a water-bath and the residue dried *in vacuo*. This residue, termed by Schützenberger fibrin-peptone, was found on analysis to contain 49.18 per cent. of carbon, 7.09 per cent. of hydrogen, and 16.33 per cent. of nitrogen, thus agreeing very closely with true fibrin-peptone as analyzed by Kühne and myself. Further, Schützenberger showed that the fibrin in undergoing this transformation had taken on 3.97 per cent. of water. But to my mind the most significant fact connected with this experiment is the positive evidence it affords, not only of hydration as a feature of peptonization by pepsin-acid, but that this greatly diminished content of carbon, so characteristic of peptones, and to a less extent of deuteroproteoses, is wholly independent of the methods of separation and purification ordinarily made use of. Thus, Schützenberger, in the above experiment, did not attempt any separation of individual bodies. Proteolysis was carried out under conditions favoring maximum conversion into peptone, and the resultant product, or products, was analyzed directly without recourse to any methods of precipitation or purification. To be sure, the substance analyzed could not have been peptone entirely free from proteose, but in any event it represented the terminal products of pepsin-proteolysis, and like true amphopeptone contained 3.5 per cent. less carbon than the original fibrin. Hence, we may conclude, without further argument, that peptonization in gastric digestion is the result of distinct hydrolytic action, in which the original proteid molecule is gradually broken down, or split apart, into a number of simpler molecules, the proteoses and peptones.

Peptones, *i.e.*, amphopeptones, are the final products of gastric digestion; but to how great an extent is actual peptonization carried on in pepsin-proteolysis? As we have seen, syntonin, primary proteoses, secondary proteoses, and peptones are all products of pepsin digestion, and it might perhaps be assumed that ultimately all of a given proteid undergoing pepsin-proteolysis would be converted into amphopeptone. Examination, however, shows that such is not the case, at least in artificial digestion experiments. Peptones are truly formed, and many times in large amount, but never under any circumstances have I been able to effect a complete transformation of any proteid into true peptone by pepsin-proteolysis; there is always found a certain amount of proteoses more or less resistant to the further action of the ferment. Obviously, the nature and proportion of the individual products formed in any digestive experiment are dependent greatly upon the attendant conditions; but even with a large amount of active ferment, an abundance of free hydrochloric acid, a proper temperature, and a long continued period of digestion, even five and six days, there is never found a complete conversion into peptone. Indeed, the largest yield of peptone I ever obtained in an artificial digestion is sixty per cent., while the average of a large number of results under most favorable circumstances is somewhat less than fifty per cent.[1]

We understand that peptones are the products of the hydration and cleavage of previously formed proteoses. The primary proteoses pass into secondary proteoses and these into peptones, but for some reason this transformation after a time becomes a slow and gradual process. At first there is a marked and rapid progression; the proteid undergoing proteolysis is rapidly dissolved, and both proteoses and peptones may be detected in abundance. But if we continue to watch the changing relations of primary and secondary proteoses and peptones, we find that progression soon ceases to be rapid, and eventually

[1] Recherches sur la constitution chimique des peptones. Comptes Rendus, tome 115, p. 208.

[1] Chittenden and Hartwell: The Relative Formation of Proteoses and Peptones in Gastric Digestion. Journal of Physiol., vol. xii., p 12.

travels onward at a snail's pace. Thus, in one experiment with coagulated egg-albumin, there was found at the end of forty-eight hours' digestion with pepsin-hydrochloric acid, only thirty-seven per cent. of peptones with fifty-eight per cent. of proteoses, and yet digestion had been sufficiently vigorous to allow of a complete solution of the proteid in two hours. At the end of seventy-two hours the amount of peptones had increased to about forty-two per cent., the proteoses having correspondingly diminished; but even at the end of seventeen days only fifty-four per cent. of peptones were to be found, thus affording striking evidence of the slow conversion of the first formed products into peptones.

Naturally, the individual proteoses show marked differences in their rate of conversion into secondary or final products. Take as an illustration some results[1] obtained with caseoses formed in the digestion of the casein of milk. Thus, heterocaseose, a primary product, yielded only fifteen per cent. of peptone after ninety-four hours at 40°C. with a strong pepsin-acid solution. Protocaseose, however, containing some deuterocaseose, under like conditions, yielded thirty-two per cent. of peptone in one hundred and nineteen hours, while pure deuterocaseose gave sixty-six per cent. of peptone in one hundred and thirty-seven hours. Evidently, then, the first formed soluble products of gastric digestion, *i.e.*, the primary proteoses, are only slowly converted into peptone, since they must first pass through the intermediate stage of deuteroproteose, which is plainly not a rapid process. The deuterobody, on the other hand, once formed is more rapidly converted into peptone, but even this is in no sense a rapid process. Hence, in the artificial digestion of proteids with pepsin-hydrochloric acid, solubility of the proteids may be quite rapid, and even complete in a very short time, but the resultant products will be mainly proteoses and not peptones. The latter are truly formed and in considerable amount, but proteoses either as primary or secondary bodies are invariably present and usually in excess of the peptones.

In this connection the question naturally arises how far we are to trust these results in their bearing on the natural process of digestion as it occurs in the living stomach. Obviously, the conditions are quite different in the two cases. In artificial digestions, we have especially the influence of an ever-increasing percentage of soluble products on the activity of the ferment, a condition of things generally considered as more or less inhibitory to enzyme action. We have attempted to measure the real value of this influence by experiments[2] conducted in parchment dialyzing tubes, in which the conditions are made favorable for the removal of at least some of the products of digestion as fast as they are formed. In these experiments the dialyzer tubes containing the proteid and pepsin-acid were immersed in a large volume of 0.2 per cent. hydrochloric acid (about three litres), which was gradually changed from time to time, the whole mixture being kept at 40° C. during the entire period of the experiment. The extent of peptonization was then ascertained by analysis of both the contents of the dialyzer tubes and of the surrounding acid, the results being compared with those obtained from control experiments carried on in flasks. Without considering the results in detail, it may be mentioned that the slow and incomplete peptonization so characteristic of artificial gastric digestion is not materially modified by this closer approach to the natural process. The several digestions carried on in the dialyzer tubes were certainly accompanied by a fairly rapid withdrawal of the diffusible products of digestion, yet no noticeable increase in the amount of peptone formed was observed. The results certainly favor the view that the conversion of the primary products of gastric digestion into true peptone is a slow and gradual process, even under the most favorable circumstances, and that this lack of complete peptonization is not due to accumulation of the products of digestion, but is rather an inherent quality of pepsin-proteolysis under all circumstances.

In these dialyzer experiments it was observed that not only did peptones diffuse, but also the proteoses. In fact, it was found that six to eight per cent. of the proteoses formed passed through the parchment walls of the dialyzer tubes into the surrounding acid in the nine hours' digestion. This led to a study of the diffusibility of proteoses in general, from which we were led to conclude that these bodies possess this power to a greater degree than had hitherto been supposed. As might be expected, it was also found that the attendant conditions modify materially the rate of diffusibility; the two factors especially prominent being temperature and the volume of the surrounding fluid. Thus, 1.9 gramme of protoalbumose dissolved in 200 c.c. of water and suspended in 4.5 litres of water heated to 38° C., diffused through the parchment tube to the extent of 5.09 per cent., while at 10° C. diffusion amounted to only 2.57 per cent. Under somewhat similar conditions, pure peptone diffused to the extent of eleven per cent. in six hours at 38° C. Somewhat singular, however, was the result obtained with deuteroalbumose; this proteose showing a diffusibility considerably less than that of the proto body. But as Kühne[1] has independently obtained essentially the same results, this apparent anomaly cannot depend upon any errors of work.

It is of course to be understood that diffusion experiments made with dead parchment membranes cannot necessarily be expected to throw much light upon the rate of absorption of these bodies through the living membranes of the stomach and intestine, where, as Waymouth Reid[2] has well said, we have to deal with an absorptive force dependent, no doubt, upon protoplasmic activity, and comparable, in part at least, to the excretive force of a gland-cell. Furthermore, in considering absorption as it occurs in the living stomach, we must necessarily give due weight to the selective power of the epithelial cells, a power which may be far more potent even than we suppose. Hence, without attempting at this point to draw any broad deductions from our experiments we may simply lay stress upon the facts themselves, viz., that the primary products of pepsin-proteolysis are diffusible, and, like true peptones, are capable of passing through animal and vegetable membranes, although to a less extent. We may further emphasize the fact that experiments of this character on diffusibility can, at the most, only indicate general tendencies, since every variation in the attendant conditions will exercise some influence upon the final result.

With reference to the bearing digestive experiments made in dialyzer tubes have upon the natural process as carried on in the living stomach, we must necessarily grant that the conditions approximate only in the crudest way to those existent in the alimentary tract. At the same time, if complete peptonization is characteristic of pepsin-proteolysis in the stomach, and failure to obtain such results in an artificial digestion is due to lack of withdrawal of the diffusible products formed, then certainly the experiments carried on in dialyzer tubes, with abundant opportunity for diffusion, and with a large excess of free hydrochloric acid, should show some indications of increased peptone formation. But none were obtained.

It is more than probable that the rate of absorption of diffusible products from the stomach has been overestimated.[3] Lea, for example, assumes that, "normally the products of digestion, whether proteid or carbohydrate, are never met with in either the stomach or intestine in other than the smallest amounts, frequently to be described as merely traces." This certainly implies a far more rapid absorption of proteoses and peptones from

[1] Chittenden and Hartwell, loc. cit., p. 22.

the stomach than results seem to justify. Indeed, recent facts obtained by Brandl,[1] working under Tappeiner's direction, tend to show that absorption from the stomach is, under some circumstances at least, comparatively slow. Brandl's experiments were conducted on large and vigorous dogs with gastric fistula, the stomach being shut off from the intestine by the simple introduction of a small rubber balloon into the pylorus, which when dilated completely closed the orifice. By carefully conducted experiments, it was shown that pure peptone, entirely free from proteose, is absorbed from the empty stomach in proportion to the concentration of the peptone solution. Thus, 7.5 grammes of peptone dissolved in water in such proportion as to make a five per cent. solution, and allowed to remain in the stomach for two hours, lost by absorption only 0.28 gramme, equal to 2.68 per cent. of the peptone introduced. Under similar conditions a ten per cent. aqueous solution of peptone lost only 4.5 per cent. by absorption. On the other hand, when peptone was introduced in larger quantity, viz., in a twenty per cent. solution, absorption amounted to thirteen per cent. in two hours.

It is thus evident that pure peptones, even when taken into the stomach in fairly large amounts, and under conditions very favorable for rapid absorption, pass into the circulating blood very slowly. Obviously, however, one must not lose sight of the fact that when digestion is under way and the volume of blood consequently increased, there may be a corresponding rise in the rate of absorption. There is perhaps a hint of this conclusion in the influence of alcohol on the absorption of peptone as brought out by some of Brandl's experiments. Thus, it was found that when alcohol was added in considerable quantity to a ten per cent. solution of peptone, the stomach mucosa was greatly reddened, while in two hours the absorption of peptone amounted to 11.8 per cent. But in any event, these results certainly do not favor the view that the products of gastric digestion are absorbed as soon as they are formed. It is, no doubt, quite different in the intestine, but in the stomach, where pepsin-proteolysis occurs, we have, I think, no grounds for assuming that either peptones or proteoses are rapidly absorbed. Hence, it might perhaps be considered that the results of pepsin-proteolysis in the living stomach are much the same as those obtained in artificial digestion experiments.

Still there are other differences between natural digestion and artificial proteolysis than those connected with the possible absorption of the more diffusible products of digestion. Thus, in the living stomach there is an ever-increasing secretion of hydrochloric acid, and perhaps also of pepsin, more or less proportional to the extent of proteolysis. On this point Brandl's experiments again give us some light. Thus, it was found that the introduction of an aqueous solution of peptone into the empty stomach led to the secretion of an acid fluid containing on an average 0.24 per cent. HCl, while, under similar conditions, the introduction of sugar or potassium iodide was followed by the secretion of a fluid containing on an average only 0.13 per cent. HCl. Further, the absolute amount of acid found after the introduction of peptone was far greater than when sugar or iodide was introduced, since peptone led to an increase of at least fifty per cent. in the volume of fluid secreted. Hence, proteolysis in the living stomach may give rise to such an increased production and secretion of hydrochloric acid that formation of the terminal products of gastric digestion may be greatly accelerated. That such in fact is the case, I have no manner of doubt, but that it may result in the complete conversion of the so called primary and secondary proteoses into peptone I very much question. In fact, such examinations as I have made of the stomach contents after a suitable test-meal have always resulted in the finding of a relatively large amount of proteoses. To be sure, true peptone may be detected and in fairly large amounts, but whenever a quantitative determination of the relative proportion of the two has been made, the proteoses have always been in excess. I have already reported elsewhere the results of some experiments in this direction made on a healthy young man, where the stomach contents were withdrawn at varying periods after the ingestion of weighed amounts of coagulated egg-albumin. Thus, in one experiment[1] the stomach was thoroughly rinsed with water, after which 138 grammes of finely divided coagulated albumin, equal to 16 grammes of dry albumin, were ingested. Three quarters of an hour thereafter, the stomach contents were withdrawn by lavage and analyzed. As a result, 1.41 gramme of albumoses were separated and weighed, and 0.84 gramme of peptones, the relative proportion being expressed by sixty-two per cent. of albumoses and thirty-seven per cent. of peptones calculated on the 2.25 grammes of soluble products recovered. This expresses the general character of the results obtained in experiments of this nature, and in my opinion adds emphasis to the statement already made, that complete peptonization is not a feature of pepsin-proteolysis, either in the artificial or in the natural process as it takes place in the living stomach.

Gastric digestion is to be considered rather as a preliminary step in proteolysis, preparatory to the more profound changes characteristic of pancreatic digestion, in which the ferment trypsin is the important factor. We can thus see how, as in the case of Czerny's dogs, an animal may be perfectly nourished without a stomach, digestive proteolysis being carried on solely by the pancreatic fluid. You will remember that two of the dogs operated on by Czerny and his pupils lived between four and five years after the operation, with the stomach completely removed, and yet during this period they were well nourished and ate all varieties of food with apparently a normal appetite.[2] Evidently, then, in some cases at least, digestive proteolysis can be carried on without this preliminary action of the gastric juice. Ogata[3] arrived at essentially the same conclusion by the establishment of a duodenal fistula, shutting off the stomach from the intestine by means of a small rubber ball which could be inflated with water. On then introducing coagulated egg-albumin and other forms of proteid matter into the duodenum, he found that digestion was at least sufficiently complete to satisfy all the demands of the system. The only unsatisfactory result was with collagenous foods, which plainly showed the need of a preliminary acid digestion. More recently still, Cawallo and Pachon,[4] working in Richet's laboratory, have studied the digestibility of different kinds of proteid foods in a dog, upon which they had performed a gastrectomy; the entire fundus, as well as the pyloric portion, of the stomach having been removed. In an animal so operated upon, after recovery was complete, solid food, as meat, was completely digested when taken in small quantities at a time. Raw meat, however, was less completely utilized, the fæces showing portions of undigested fibres. Still, it was apparent that intestinal digestion alone was capable of accomplishing all that was necessary for the complete nourishment of the animal, when it had once become accustomed to the changed condition of its alimentary tract.

These facts are cited not to belittle the importance of gastric digestion in the nutrition of the body, but rather to emphasize the probability that pepsin proteolysis is simply a preliminary step in digestion. That its function is not in the direction of a complete peptonization of the proteid foods ingested, but that its action is especially directed to the production of soluble products, proteoses, which can be further digested in the small intestine, or perhaps directly absorbed after they have passed through the pylorus, or even from the stomach itself to a certain extent.

Some Physiological Properties of Proteoses and Peptones.

It is very evident from what has been said that all forms of proteid matter, *i.e.*, all the members of the three main groups spoken of in our classification of the proteids, excepting only nuclein, recticulin, and the keratins, are capable of undergoing proteolysis with pepsin-hydrochloric acid. Further, in every case the main products of the transformation are proteoses; viz., albumoses, caseoses, gelatoses, vitelloses, myosinoses, etc., according to the nature of the proteid undergoing proteolysis; true peptones being formed in less abundance. Corresponding to each of these groups are primary and secondary proteoses, all possessed of many points in common, both chemical and physiological, yet differing from each other in many minor respects. These are the important products of gastric digestion, of pepsin-proteolysis, and it may be well to consider for a moment some of the physiological properties of the proteoses and of peptones as well, in order that we may the better comprehend the general nature of these substances with reference to their possible action in the economy.

As far back as 1880, Schmidt-Mülheim [1] discovered that the injection of aqueous solutions of peptone into the blood-vessels of living dogs was attended by a series of remarkable phenomena. Thus, the animal passed at once into a condition of narcosis resembling that produced by chloroform, accompanied by a fall of general blood pressure so great that the animal was liable to die, as from asphyxia. Further, there was evidence of some marked change in the condition of the blood, as indicated by loss of the power of spontaneous coagulation, while the peptone itself evidently underwent some alteration, or else was rapidly eliminated, since it could not be detected in the blood a short time after its introduction. These experiments, however, were not conducted with true peptone but with Witte's "peptonum siccum," which at that time, at least, was composed in great part of proteoses. The general character of these interesting results was confirmed by Fano,[2] who found that the injection of so-called peptone in the proportion of 0.3 gramme per kilo. of body-weight was sufficient to bring about complete narcosis together with loss of coagulability on the part of the blood. Very suggestive, however, was the fact that Fano, on trying similar experiments with the peptone formed by pancreatic digestion, viz., with antipeptone, which presumably contained a far smaller proportion of proteoses, failed to obtain like results; the tryptone so called being exceedingly irregular in its action, in many cases producing no effect whatever.

The discovery at this date of the several albumoses, and their presence in large amounts in all so-called peptones, led to a study of their physiological action with special reference to the observations of Schmidt-Mülheim and Fano. Politzer,[3] working under Kühne's guidance, was the first to experiment in this direction, and his results are full of interest as throwing light on the action of the individual albumoses. Thus proto-, hetero-, and deutero-albumose are all active physiologically, giving rise when injected into the veins of dogs and cats to strong narcotic action, varying somewhat in intensity in different individuals. There is also produced a marked fall in blood-pressure, due apparently to vaso-motor paralysis, the action being manifested chiefly, if not wholly, on the splanchnic region. Thus, after an injection of one of these albumoses, the mesenteric vessels are always strongly congested, accompanied frequently by the appearance of a bloody serum in the peritoneal cavity. Narcotic action is manifested only so long as the blood-pressure remains subnormal, and is due presumably to this marked accumulation of blood in the large abdominal veins, thus leading to anæmia of the brain. Albumoses and peptones injected into the jugular vein likewise produce fever, presumably through some action on the nervous system by which the equilibrium of tissue metamorphoses is interfered with.[2]

Further, Politzer found that all of the albumoses either delayed or prevented altogether the coagulation of the blood, in conformity with the observations of Schmidt-Mülheim and Fano. In all of these actions the primary albumoses appeared most effective, deuteroalbumose least so. Heteroalbumose, however, was constantly most active, especially in delaying the coagulation of the blood. With amphopeptone there was far less narcosis and less diminution of blood-pressure, while the effect on the coagulability of the blood was more or less variable, frequently being entirely negative. Antipeptone, on the other hand, was found almost wholly wanting in any constant effects, although in one instance deep narcosis was produced. Thus, from Politzer's experiments, it was made clear that the albumoses, when introduced directly into the blood current, possess a far greater toxic action than either amphopeptone or antipeptone. Albumoses, in sufficiently large doses, were invariably fatal, while peptones never produced fatal results so long as the kidneys of the animal remained intact. The extreme solubility and diffusibility of peptones, coupled perhaps with their marked diuretic action, lead to rapid elimination through the kidneys, and their consequent removal from the system.

Many of these observations made with the albumoses I have repeated with several of the proteoses and peptones more recently studied, as protocaseose, protoelastose, the globuloses, and others. The results may be taken as practically confirmatory of the older observations, and I make mention of them in this general way simply to emphasize the fact that all of the proteoses, though perhaps showing individual peculiarities, are possessed of marked physiological properties, which plainly testify to their toxic nature when introduced directly into the blood-current.

Young animals are particularly sensitive to the injection of proteoses into the blood, even when the introduction takes place very gradually.[2] Thus, a young, healthy dog of 2 kilos. body-weight, eight weeks old, died in one hour after the injection into the jugular vein of 1 gramme of protoalbumose in 20 c.c. of water, thus affording a good illustration of the extreme toxicity of this albumose when introduced directly into the blood.

Of greater interest, physiologically, are the changes the individual proteoses undergo after their injection into the blood. As already stated, peptone so injected may appear in the urine wholly unaltered. Thus, Neumeister [3] has made injections of both amphopeptone and antipeptone in the case of dogs, and was able to detect the peptone very quickly in the urine. I have made like experiments with other forms of peptone and obtained similar results; thus, a pure amphopeptone formed from casein by pepsin-proteolysis (2 grammes in 15 c.c. water) was injected into the jugular vein of a dog weighing 5 kilos. The urine collected during several hours after the injection was heated to boiling, and saturated while hot with ammonium sulphate. The filtrate, on being tested with cupric sulphate and potassium hydroxide, gave a fairly strong biuret reaction for peptone. Another similar experiment made with antipeptone, formed from the myosin of muscle-tissue gave like results.

With proteoses, however, different results are obtained, as Neumeister [4] first pointed out. These bodies introduced into the blood undergo more or less of a change prior to their excretion in the urine, the change partaking of the character of a hydrolytic cleavage in which the primary proteoses are transformed into secondary

proteoses, while deuteroproteoses are changed into peptones. This is not necessarily to be interpreted as meaning that the full equivalent of the proteose injected appears in the urine, but that the portion which is eliminated through the kidneys tends to undergo a transformation somewhere *en route*, akin to the change produced in pepsin-proteolysis. As to how common or complete this transformation is under the above circumstances, we have no positive knowledge. Such a hydrolytic change certainly occurs in the case of the dog, and the experimental evidence is in favor of the view that the transformation is effected in the kidneys, by the pepsin secreted through the urinary tubules, where there is momentarily a formation of free acid. In the rabbit, on the other hand, no such change occurs; the urine from this animal contains practically no pepsin, and consequently the proteoses eliminated through the kidneys are excreted unaltered. As, however, the experiments of Stadelmann [1] and others have shown that the urine of all carnivora, and of man as well, contains a ferment which, on the addition of a suitable amount of hydrochloric acid, will digest fibrin with formation of the ordinary products of pepsin-proteolysis, it is to be presumed that all proteoses passing through the kidneys will undergo at least some change prior to their excretion in the urine.

However this may be, it is very evident that the proteoses formed in gastric digestion cannot be absorbed as such directly into the blood-current. Introduced into the blood, they behave in such a manner as to warrant the conclusion that they are truly foreign substances, and the system makes a brave endeavor to remove them as speedily as possible. The same may be said of amphopeptones, from which we may conclude that all of these products of pepsin-proteolysis undergo some transformation during the process of absorption, by which their toxicity is destroyed and their nutritive qualities rendered fully available for the needs of the body. Discussion of this question, however, will be left until the next lecture.

In view of these pronounced physiological properties of the proteoses, it is interesting to recall the now well-known fact that many of the chemical poisons produced by bacteria are proteose-like bodies, chemically, at least, closely akin to the proteoses resulting from pepsin-proteolysis. Thus, Wooldridge [2] as early as 1888 pointed out that an alkaline solution of tissue fibrinogen exposed to the action of anthrax bacilli suffered some change, so that when introduced into the blood it possessed the power of producing immunity to anthrax. This observation was verified by Hankin,[3] who further showed that the substance formed by the anthrax bacilli was a veritable albumose, and that it truly possessed the power of producing immunity. Sidney Martin [4] carried the matter still further, and by growing the anthrax bacilli in a pure solution of alkali-albuminate prepared from blood-serum, proved the formation of both primary and secondary albumoses, as well as of peptone, leucin, tyrosin, and a peculiar alkaloidal substance of pronounced toxic properties. Martin finds that the albumoses are not as poisonous as the alkaloid, and surmises that the alkaloid is contained in the albumose molecule in the nascent state; further, he suggests that the albumoses in small doses may exert some protective influence, while in larger doses they act as vigorous poisons. How true this may be I cannot say, but my own experience convinces me that the anthrax bacilli grown in a culture medium composed of alkali-albuminate, prepared from egg-albumin, to which the necessary inorganic salts and some glycerin have been added, do give rise to albumoses and peptones which are truly endowed with toxic properties.

Albumose-like bodies have also been obtained by Brieger and Fränkel [5] with the bacillus of diphtheria. These, too, were endowed with powerful poisonous properties, and when introduced into the tissues of the body gave rise to reactions resembling those produced by the Löffler bacillus. In my own laboratory recent experiments made with the bacillus of glanders have shown that when grown in a slightly acid medium containing alkali albuminate, albumoses, peptones, and crystalline bodies such as leucin and tyrosin are formed in considerable quantities. Kresling [1] has reported similar results. With the tubercle bacilli, many like results have been recorded. Thus, among others. Crookshank and Herroun [2] have reported the finding of albumoses, peptone, and a ptomaïne when the bacilli have been grown in glycerin agar-agar and also in fluid media.

Koch [3] has made a special study of the albumose which he considers as the specific toxic agent of the so-called tuberculin. This albumose was found by Brieger and Proskauer [4] to have a somewhat peculiar composition, inasmuch as it contains forty-seven to forty-eight per cent. of carbon and only 14.73 per cent. of nitrogen, agreeing, however, in this respect very closely with the peptone formed from egg-albumin by the action of bromelin.[6] Still more recently, Kühne [6] has made a thorough study of this albumose, as well as of the other products elaborated by the growth of the tubercle bacillus. He designates all of the peculiar albumoses formed by these bacilli as *acrooalbumoses*. They are endowed with marked chemical and physiological properties, causing a rise of temperature when injected into the blood, as well as other phenomena more or less pronounced. It is thus evident there is ample ground for the statement that all nutritive media in which pathogenic bacteria have been planted are liable to contain, sooner or later, toxic substances, many of which at least are closely related to, if not identical with, the albumoses. It is not my purpose, however, to consider these points in detail, nor to quote the many results obtained by other workers in this direction.

I wish merely to call attention to the fact that the proteoses, and likewise the peptones formed by pepsin-proteolysis, are more or less toxic when introduced directly into the blood, and that they share this property with the proteoses formed by bacterial organisms, or by the enzymes which they give rise to. In other words, these primary cleavage or alteration products of the proteid molecule, however produced, are more or less poisonous, and if introduced into the blood-current without undergoing previous change may show marked physiological action. It is, of course, not to be understood that these bodies are all alike. They are surely closely related and possess many points in common, especially so far as their chemical properties are concerned, but their chemical constitution and their physiological action must vary more or less with their mode of origin.

In any event, it is very evident that the proteoses and peptones formed in the alimentary tract by pepsin proteolysis must undergo some transformation, before reaching the blood-current, by which their peculiar physiological properties are modified. This modification may be associated with a conversion into the serum-albumin, or globulin of the blood. However this may be, the fact remains that these proteoses formed so abundantly during digestion can be absorbed and serve as nutriment for the animal body, but between their formation as a result of proteolysis and their passage into the blood they are exposed to some agency, or agencies, doubtless in the very act of absorption, by which a further transformation is accomplished. With this point we shall be able to deal more in detail in the next lecture.

HYGIENIC VS. DRUG TREATMENT FOR TYPHOID FEVER.

By CHARLES E. PAGE, M.D.,

BOSTON, MASS.

"The chief advantage of the medicinal antipyretic treatment seems to be that the patient is able to die with an almost normal temperature," remarks Dr. Simon Baruch,[1] in an editorial on the treatment of typhoid fever. This is not the off-hand fling at medicine of a tyro, or quack, but the careful statement of a veteran among New York's leading physicians.

A "notable discussion" has been going on for the past five years among the most thoughtful medical men in this country, as to the crying need of a radical modification from the prevailing treatment in acute diseases. Typhoid fever being one of the most prevalent, as well as one of the most distressing and fatal of these disorders, has formed the chief topic in the discussion; but it is very important for us to know that, while the technic, or detail of treatment, differs with every disease, the principle involved applies equally to the treatment of scarlet fever, pneumonia, influenza fever (la Grippe), etc.

It is a question of the Brand (cold bath) treatment for typhoid fever, on the one hand, and the expectant, or symptomatic drug treatment, on the other. Concerning the results of the latter, Dr. Delafield, in an instructive paper on typhoid fever, read before the New York Academy of Medicine, states that the mortality in the city hospitals alone, from 1878 to 1885, averaged 24.66 per cent., while the records of the Board of Health of New York (1876 to 1885) show 7,712 cases of typhoid fever, with 3,184 deaths, or about forty-one per cent.

To the writer's mind it is beyond the possibility of belief that so large a proportion of typhoid fever cases would result fatally if left absolutely alone with no treatment whatsoever. If this strikes anyone as a rash statement, let him study the question carefully after reading the following, from Dr. George L. Peabody, another of the prominent regulars of New York. In a paper read before the Practitioners' Society, New York, December 6, 1889, Dr. Peabody says:

"The results in the treatment of typhoid fever continue to be so bad in general in this country as to constitute a chronic opprobrium to the art of medicine. . . . Those who still adhere to the expectant plan of treatment are still in the large majority here. The expectant plan seems in a general way to make us quite content with our bad results; and to lead us to expect the patient to die if he becomes gravely ill." Can human language describe a more wretched state of affairs than this?

One distinctive feature in the "fatal expectant plan," as it has well been called, is that the physician expects in typhoid fever, a "run" of twenty-one to twenty-eight days, as a matter of course, during which the temperature of the patient varies between 105° F. and the normal point, though it often goes below normal, under the influence of stiff doses of antipyretic drugs.

The following description and the wretched effects of the regular drug treatment appear in Dr. Peabody's paper to which allusion has been made: "In this plan of treatment, practically nothing is done[2] unless symptoms in themselves very disturbing or grave, or even threatening, develop, and then much is often done that is likely to be pernicious in its effects. If a patient have a headache, he receives the bromides or an ice-cap, or both, depending on its severity; if he develop a bronchitis, he is given opium, or cough mixtures, or inhalations; if he suffer from tympanites, he is given turpentine, or turpentine stupes are applied; if he have diarrhœa, he is given opium and astringents; if hemorrhage from the bowels occur, to the opium is added tannic acid or gallic acid, or some equally useless and disturbing drug; if he become delirious, the dose of opium is increased, or he is physically restrained; and, most pernicious of all, if his temperature reach what is considered a dangerous height, an elevation which, long continued, would become incompatible with life, he is given a *large dose* (his own italics) of some antipyretic drug, and his temperature is suddenly reduced to a level which may be several degrees below the normal. Often this objectionable procedure is repeated in an almost rhythmical way for several days or weeks; and if, accompanying the fall of temperature thus produced, there is a degree of prostration and feebleness of heart which is alarming in itself, then, to counteract this bad symptom for which the drug and the doctor are responsible, alcoholic and other stimulants are given in large amount.

"This method of treatment," he continues, "if it be proper to call that a *method* which seems to lack all true system, is often dignified by its advocates by the appellation *rational*. In fact, however, it would be difficult to devise a more irrational method."

Could any mental scientist, or faithist, formulate a more villainous description of the routine drug treatment than is given above by one of the foremost men in the profession, who has, himself, but recently become a convert to the Brand method in typhoid fever? And yet, he has described the still prevailing treatment throughout this country, from city to cross-roads. If the people are, or seem to be, satisfied with it, it is simply because they have no idea of a better way.

Having shown by statistics that none can dispute the undue mortality from the drug and stuffing treatment, and by the evidence of an acknowledged authority the manner in which it is brought about, let us consider the slight mortality under the bath method, and the way in which the happy results are achieved.

In 19,017 cases of typhoid fever, according to statistics furnished by Ziemsen, Liebermeister, Brand, and others, the mortality was seven per cent., although the cold-water treatment was, in these cases, only practised in a "half-hearted, or modified form." From twenty-three German and French sources, Brand obtained statistics that clearly demonstrated that this treatment, as originally recommended by him, in 1861, has reduced the mortality in typhoid fever to less than four per cent., the basis of these statistics being 5,573 cases, and although these statistics were published six or seven years ago, there has been no claim from any quarter that they have been or can be controverted.

The number treated by Juergensen, Vogl and Brand themselves, up till 1887, amounted to 1,223 cases, of which twelve only died, or one per cent. Moreover, not a single one of these twelve deaths occurred in any case that came under treatment before the fifth day. There can be no doubt as to the exactness of these figures, since the cases were observed by well-trained medical men in university clinics and military hospitals.

The Brand method is evidently based upon the theory that the fever, so far from being in itself the disease, is rather the means of cure. Hence, no measures are resorted to for the purpose of at once reducing the temperature.

The aim is to strengthen the heart, and refresh the nervous system, to promote the comfort of the patient, to keep the skin moist and in condition to perform its functions, and, in brief, to help the organism in its efforts to eliminate the offending matters and to heal the lesions in the stomach and intestines; and all this is accomplished through the invigorating influence of the bath.

[1] The Lessons of a Notable Discussion, Journal of Balneology, July, 1892.

[2] One very harmful thing is always done from the start, viz.: the patient, though without appetite, perhaps even loathing all thought of food, is constantly fed. He must have so many ounces of some kind of slop-food, commonly milk, with the addition at stated times of beef-tea (known to the expert as practically identical with urine), and usually a stimulant at stated times, or when the patient seems to require it; champagne is often given persistently, "because it is the only thing the stomach will retain." If the object sought were to produce the ugly symptoms enumerated by Dr. Peabody, no better scheme could be invented than the foregoing.

It is all in direct contrast, in practise, to the routine drug method, which I can liken to nothing better than a system of constant wheel-trigging, or hanging on behind when nature is pulling a big load up hill.

The Brand method consists of immersing the patient in a comparatively cold bath whenever the temperature rises to 103° F., or above, for the space of fifteen minutes, constant flat-hand rubbing of the body being practised by the attendant, and, so far as possible, by the patient himself, during every moment of the time. Under no circumstances is this friction of the skin to be omitted during the bath. "By these frictions the superficial cutaneous vessels are dilated, and because of the reaction induced by it the skin, which was of a dead white when the patient entered the bath, becomes of a ruddy hue under the hands. It may become cyanotic if friction does not actively counteract the contraction of the arterioles produced by the cold impact."

The temperature of the water should be about 65° to 67° F. It may be a full bath, to the neck, if convenient, or the "half bath" with laving of the water over the body, and the patient should wear a heavy, cold compress about the head on entering the tub, or the water should be freely laved over the head.

On emerging from the bath the night-gown may be put on without drying the skin, and the patient well wrapped in blankets immediately, and returned to bed to be snugly tucked in sufficient covers to secure soon a feeling of comfortable warmth, which may be hastened, upon occasion, by means of a sufficient degree of massage or muscle squeezing, over the bed covers, the feet receiving attention of the same character. It is much better to secure warmth of the extremities by friction and pressure, than by the application of direct heat. The Germans have an adage to the effect that the fever patient cannot catch cold; and it were well if nurses and other attendants could so comprehend this matter as to avoid the mischief so constantly done through excessive fear of draughts, of throwing aside the bed covers, and the like, when they promote the patient's comfort and chances of recovery. A sufficiently ventilated sick-room is seldom found, and even when the attending physician does his best to secure fresh air for his patient he finds it difficult to persuade the household to fully co-operate with him.

The bath may be repeated every three hours, so long as the temperature of the patient remains, or returns to 103° F. It often happens that no appreciable reduction results from the bath, but as we have already observed, the immediate object sought is not the reduction of temperature. There is nothing especially exhilarating in the thought of being taken from a warm bed and plunged into a cold bath—far from it; but the very persons who would disclaim against such a procedure for a fevered body, have been very likely themselves plunged into the sea to kick and splash about in water considerably below that of the bath we are considering, and often under conditions when they really derive harm from their sport, as in the case of "thin blooded," or anæmic persons, who emerge from the water with blue lips and discolored finger-nails. Such "pleasure seekers" are far more chilly and uncomfortable than any patient in the Brand bath, though even the latter may not find the bath particularly agreeable. It does, however, often prove so. In the case of one little girl six years of age, residing in St. Paul, whose treatment I directed by telegraph, the patient went first to the bath, with considerable trepidation, but so well pleased was she with the effects that, to quote from her mother's report, "she actually coaxed for, and received, four more baths during the day." Fasting and cold bathing aborted the disease. She was allowed nothing but water for the first seventy two hours, and, in fact, rather gloried in her three days' fast, at the expiration of which she was practically convalescent. She made a very rapid recovery. Only one bath was given on the second day, and none at all thereafter. Lest it might be surmised that the case was not typhoid fever, since the doctor and patient were too widely separated to make the diagnosis clear, I will hasten to state that the family physician was in attendance, and declared the case to be a typical one. It was the second case in the family, the father being first attacked. He had for upward of two weeks the regular drug treatment, when they became frightened and wired me the symptoms and requested me to advise them. I directed that all drugging and feeding be stopped until the patient should become convalescent, giving full directions by wire upon all points from day to day. Satisfactory improvement resulted from the change in treatment, and the patient was shortly convalescent. Meantime, the little daughter was attacked, even more violently than in the father's case, but the treatment being begun at the very onset, and given to the limit, with fasting, as already remarked, she was restored to bounding health before her father was out of bed.

In all acute sicknesses there is at the onset no office for food, as there is usually no desire for it, and the condition of the stomach, and often that of the entire intestinal tract, clearly indicates to the expert dietetist that there can be no hope of digestion and assimilation, in default of which only putrefaction and all manner of mischief can result from the ingestion of food. While it is true that Dr. Brand, himself, and most of his followers feed their fever patients pretty steadily, though moderately, throughout the course of the disease, and, still, seldom lose a case that comes early under the treatment, it is doubtless true that with the modification herein recommended—the withholding of food for the first few days, and at any rate until the patient is unmistakably hungry—all curable cases would be shortened, complications lessened, and quite a proportion of cases aborted absolutely.

When constant feeding is practised the baths have to be given for many days together, the number of baths often reaching as high as forty and even more; whereas, under the fasting plan[1] baths are seldom required after the first day or two, simple sponge bathing, and perhaps the "damp bandage," being all that is required for the comfort and advantage of the patient. It is my practice to have the patient wear the damp bandage pretty constantly while the temperature remains above 101° F. It is composed of two-ply coarse linen, wrung tightly from cold water (ice water is usually best, the reaction being more prompt and complete), with two ply of same outside, and is snugly pinned about the body—at the abdomen in typhoid fever, and at the chest in pneumonia, or where the lungs are in the least threatened; and in some cases this "pack" may with advantage be wide enough to cover the body entire, from arm-pits to hips. It will require to be renewed as often as every three hours, and sometimes in half that length of time, or even less, if necessary to prevent its becoming too hot. It must not be allowed to get dry, but had better be thrown off if it cannot, or does not need to, be renewed.

In strong contrast to the effects of the regular drug treatment, as described by Dr. Peabody, are those derived from the bath method as stated by Dr. Baruch: "In typhoid fever, we have it, upon authority which we dare not question, that the cold bath refreshes the nervous system; that it deepens the respiration; that it moistens the tongue, and improves the appetite; that it steadies and slows the pulse; that it improves the digestion; that it increases the quantity and improves the quality of the urine; that it removes stupor and delirium. In short, it lends vigor and tone to the entire system, and approximates the condition of the patient so nearly to the normal that his entire aspect is changed."

Why is it that a remedy which operates so charmingly, and which is in the strictest sense regular, since a few of the most thoughtful men in the regular profession during every generation from the time of Hippocrates to the present day have made use of it, has been, and still is,

[1] See MEDICAL RECORD for February 24, 1894, for history of many cases of fasting: Should Therapeutic Fasting be Called Starving?

almost universally ignored by the profession? Alas, it is too simple for the grasp of the super-scientific youngsters, who, hearing nothing about it, or at any rate, not much, except that it is the sheet-anchor of the irregulars, not unnaturally regard it as altogether out of the regular line. There is not enough of mystery about it to impress the mind of the average medical man, whose head has been so crammed at school with drug theories (the baneful operation of which has been so graphically described by Dr. Peabody) that there is little room left for common-sense innovations after leaving alma mater. It is a matter of profound regret that none of our medical schools teaches anything of the water-treatment, except in the most superficial way.

Outside of the regular profession the water treatment has been largely used, and always with a high degree of success, and it is well for the profession to consider whether we can afford longer to allow the irregulars a practical monopoly of this most potent and beneficent remedy. So great is my appreciation of the importance of hydrotherapy, that I hail as a benefactor of the race the man who makes intelligent use of water in the treatment of disease, whether he be college bred or not; and I am not, therefore, able to share the sentiment of one of the ablest advocates of the Brand method, who speaks of the duty which the profession owes to itself and to those who intrust their lives and health to its keeping, to "wrest from the quack a weapon against disease whose power stands second to none in the catalogue of therapeutic agents." In my humble opinion the real quack is he who continues to ignore the lessons of Priessnitz and Kneipp, as well as the few of the most eminent men in the regular profession, and delays adding to his equipment this most powerful and yet soothing remedy.

It is no longer necessary to urge the safety of allowing the fever patient all the fresh water his thirst demands, but it is necessary to state that the fasting patient will not only have no extraordinary thirst, but it soon becomes necessary to prescribe water, either cold or warm, in order to maintain the fluidity of the blood, which is being constantly depleted of this element. The patient is really scavenging on the waste and effete matters which constitute, in great measure, his disease, and his blood is as well supplied with solid matters as is that of the cormorant who feeds wholesomely on the decaying carcass of a mule or other creature. It is my custom to prescribe two to four ounces of moderately, and *always soft*, hot water (with placebo) every hour or half-hour, by the clock, the amount and frequency depending largely upon the amount and complexion of the urine, which should be carefully observed from day to day.

357 Boylston Street.

A CASE OF ACUTE SOFTENING OF THE BRAIN PRESENTING HYSTERICAL SYMPTOMS AND SIMULATING HYSTERIA.[1]

By THEODORE DILLER, M.D.,

PITTSBURG, PA.

PHYSICIAN TO THE NEUROLOGICAL DEPARTMENT OF THE PITTSBURG FREE DISPENSARY; VISITING PHYSICIAN TO THE INSANE DEPARTMENT OF ST. FRANCIS HOSPITAL.

Mrs. B——, widow, aged fifty six, was referred to me by Dr. Mark Rodgers, and was seen by me for the first time March 16, 1894. She was a very stout woman, weighing over two hundred pounds, but had always led an active life and had always enjoyed exceptionally good health.

About six weeks before my first visit to her, she, upon returning from a trip to Ohio, learned of a painful affection of the right arm, from which her grand-daughter had suffered during her absence and was indeed yet, to some extent, suffering upon her return, it being still enveloped in bandages. Mrs. B—— asked many questions about it, expressed great solicitude for her grand-child, cautioning her to beware of paralysis, as several members of the family had died of some such affection. A few days later she began, in a vague manner, to complain of certain numbness in her right arm. It was jokingly suggested that her concern for her grand-child had brought on the trouble. But she persisted in saying that the numbness was growing worse each day, and afterward that she was losing strength in the arm, and still later that her right leg was becoming similarly affected. Some few days after the onset of her trouble she began to exhibit some hesitation in speech, *e.g.*: She would stop short in telling something, saying: "There! I cannot go on," or "I forgot it," or "I can't think of it now." She seemed never to be at a loss for any single word, nor did she misplace words or incorrectly name objects. These symptoms became more pronounced each day; but she continued, as formerly, to eat heartily and sleep well at night, nor was there any change in her general appearance. But all the while she insisted that her condition was very serious.

When she was informed that I was expected to visit and examine her, she manifested the liveliest interest in my coming, asking at frequent intervals whether I had arrived.

On March 16th I examined her. She was lying in bed, because, as she stated, she was unable to stand or sit up. A causal observation discovered nothing. Upon attempting to converse with her she exhibited an unwillingness or inability to reply at any length. But short replies (always relevant) came from her after a pause. I could not find that memory was markedly deficient. The mental condition was that of a real or assumed general hebetude. I placed a handkerchief over her eyes and proceeded to test sensation of her right arm with two pins. A number of times she located two pins at the normal distance; again she felt but one when two were actually in contact with her arm a foot apart; again she felt two, three, four, or five (I never used more than two); when none was in contact with her arm she felt one, two, three, or none, both with and without my suggestion. Altogether these tests were valueless, except (as it seemed to me at the time) in offering an argument showing the presence of hysteria. A sharp prick of the pin caused a quick withdrawal of the arm. The grasp of the right arm was about one-half that of the left. She complained of a corresponding numbness and loss of power in the right leg; but these were not tested. No other symptoms presented themselves. Her appetite was good and she was sleeping well. An examination of the urine showed it to be normal. After I had completed my examination she suddenly exclaimed; "Well, doctor, do you think my case is hopeless?"

I concluded that the case was a hysterical one and prescribed small doses of bromide, suggested that there would be a progressive improvement from day to day. During the week following my first visit she very slowly grew worse, as she had during the preceding week. But she managed to sit up an hour or two each day. She insisted upon the medicine being given to her regularly, reminding those about her as the time approached for its administration; evidently she considered herself a very sick woman and wished to impress others with this idea; at the same time she was apparently very watchful of all that was going on about her. It became necessary to move her from the second to the third story. At the time it was expected that she would need very substantial assistance. Her brother first carried up her easy-chair, expecting to return for her, and was surprised when near the top of the stairs, on looking back, to see the patient following close behind him unaided. For some days prior to this she had constantly required assistance in making any movements. Acting upon my suggestion, this assistance was made a form or feint instead of a real help, and seemed, her daughter stated, to be just as helpful as when it was genuine. One day when she wanted something when there was no one at hand to serve her,

[1] Paper read before the Pittsburg Academy of Medicine, April 2, 1894.

she called in a very loud, impatient voice, so that the servant on the first floor easily heard her and was startled.

By March 23d, she had apparently lost much of her interest in her surroundings, and would answer only by a "yes," or a "no;" the paralysis of the right arm and leg was apparently complete; she ate as much as usual, but had to be fed by the spoon.

March 24th.—Temperature, normal. Stupor deepening.

March 25th.—Temperature, 99.6° F. Plantar reflexes active; in general appearance looks as well as when in health. Pulse rather feeble. Respiration, slightly accelerated. Would make no reply to questions. Pupils equal and very responsive to stimulus of light. Conjunctivæ sensitive to touch. A pinch of the skin causes her to draw up her face into a painful expression. Passes urine freely in bed.

March 26th.—Temperature, 102.6° F., and respirations, 38. Swallows nourishment and medicine without difficulty.

March 27th.—Temperature, 103.6° F. Respirations, 42. Coma apparently deepening; but conjunctivæ are still sensitive, and pinching skin brings expression of pain to the face. A dose of castor-oil produced a free evacuation of the bowels. Continues to pass urine involuntarily. Swallows liquid nourishment and medicine.

March 28th.—In morning, seemed somewhat better, but in evening, condition critical. Temperature, 104° F.; respirations, 50; pulse feeble, thready, difficult to count (probably about 125). For the first time unable to

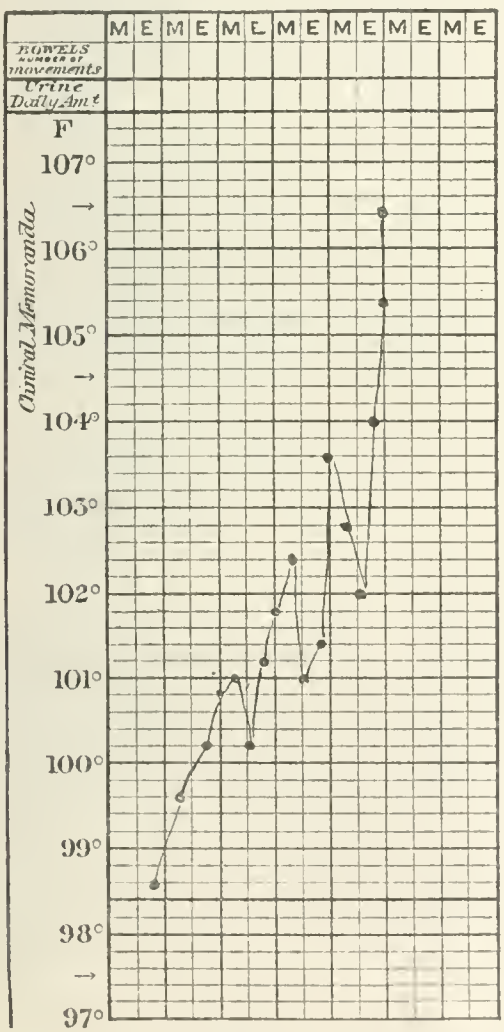

Fig. 1.

swallow; all skin reflexes absent; conjunctivæ insensible to touch. Temperature continued to rise during night, reaching 106.4° F. at 2 A.M. Death occurred at 2.45 A.M.

Autopsy, twelve hours after death. (Brain only examined.) Rigor mortis well marked. Examination of the base of the brain revealed a most remarkable condition of the arteries. The laminæ of both internal carotid arteries, just where these vessels enter the cranium at the anterior clinoid processes, were found much narrowed and entirely occluded by firm, hard, dark-brown clots. The left posterior communicating artery was completely obliterated; from its attachment to the posterior cerebral artery its diameter lessened, until it finally terminated in a thread-like extremity. Distributed over all the large arteries of the base were numerous yellowish plates of thickening ("endarteritis deformans" of Virchow) But there was no calcification present in any of these degenerated arteries. No embolus or thrombus could be discovered.

The annexed diagram of the circle of Willis shows the

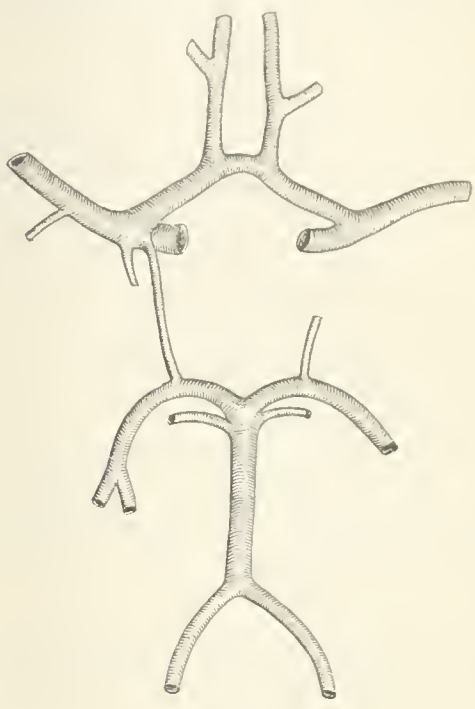

Fig. 2.

exceedingly limited source of blood-supply which the brain (especially the left hemisphere) had for probably many months. The two internal carotids being firmly plugged, the entire blood-supply was through the two vertebrals. As the left posterior communicating artery was occluded, the left hemisphere received a very deficient blood-supply, and this in a very roundabout manner, viz., *via* vertebrals, basilar, right posterior cerebral, right posterior communicating, right internal carotid, right middle cerebral, right anterior cerebral, anterior communicating, and left anterior cerebral.

An extensive softening of the left hemisphere occupy-

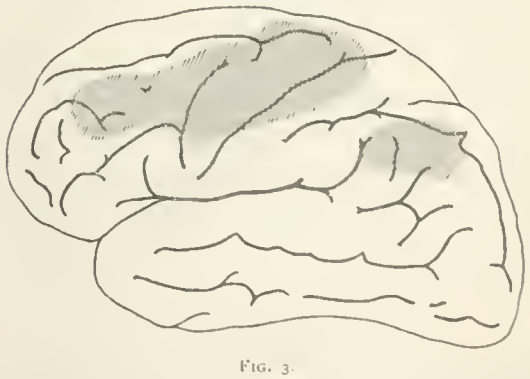

Fig. 3.

ing the upper two-thirds of the ascending frontal, extending slightly into the ascending parietal. A spot in the inferior parietal and the posterior two-thirds of the middle frontal convolution was present. The uppermost part of this softening presented, for an area equal to that

of a silver quarter, a yellowish appearance (*plaque jaune* of Charcot). The underlying white substance in the centrum ovale was softened, the process stopping a little short of the internal capsule. The basal ganglia were intact. Certain portions of the softening in the lower part of the ascending frontal presented a distinctly reddish appearance, especially in the cortex.

Remarks.—The case is one of interest viewed both from a clinical and pathological standpoint.

For a time I regarded the case as one of hysteria. Drs. Mark Rodgers and W. Jones, who saw the case, shared this view. But with the appearance of fever I began to feel that there was some organic change in the left hemisphere of the brain. The history of the case seemed to preclude hemorrhage or embolism. Meningitis and tumor also appeared unlikely. Abscess or softening then seemed to be the condition most probably present.

It is certainly remarkable that the affection should have begun as it did—having its beginning apparently as the result of a psychical impression which the patient received as the result of deep concern for the threatening paralysis (as she thought) of her grand-daughter's arm.

The morbid condition present was an acute atheromatous or senile softening. When the condition of the blood-vessels at the base of the brain is considered, it must be admitted that the predisposing conditions were, and probably had been for a long time, present, favoring an acute softening, especially in those portions of the brain supplied by the left middle cerebral artery.

To reconcile the clinical symptoms with the morbid changes present, I would suggest, in lieu of a better one, the following explanation:

The predisposing conditions for acute softening being present in such a high degree, it is evident that only a slight precipitating or exciting cause was necessary to actually produce that condition. The mental anxiety of the patient for the welfare of her grand-daughter's arm furnished this exciting cause.

CAUSATION, PATHOLOGY, AND SYMPTOMS OF RETRO-PHARYNGEAL ABSCESS.[1]

By H. W. BERG, M.D.,

NEW YORK.

To the orthopedic surgeon, the condition known as retro-pharyngeal abscess involves a diagnosis of disease of the upper cervical vertebræ or of the basilar process of the occipital bone. But clinically, this condition occurs by far more frequently as a complication of other diseases. In these latter cases there is neither disease of the cervical vertebræ, nor, indeed, any bone disease whatsoever. It is with the view of distinguishing these two varieties of retro-pharyngeal abscess, namely, those occurring as a result of bone disease, and those occurring independently of bone disease, that I wish to call attention to this subject. The clinical history of these abscesses shows a marked difference in the two varieties in respect to their etiology, pathology, symptoms, and treatment.

Etiology.—As already hinted, a considerable class of these abscesses occur in connection with bone disease, and especially with disease of the three upper cervical vertebræ. This form of abscess is analogous to psoas abscess, occurring in connection with disease of the vertebræ below the sheath of the psoas magnus; retro-œsophageal abscess, a rare and fatal form of abscess resulting from disease of the vertebræ, or, indeed, analogous in its origin to other so-called cold abscesses, occurring in connection with osteitis of the hip-, knee-, ankle-, and other joints. This form of retro-pharyngeal abscess would therefore very properly be designated as chronic retro-pharyngeal abscess, to distinguish it from the much larger group which is the result of suppuration in the soft tissues behind and around the pharynx, which should be designated as acute retro-pharyngeal abscess.

[1] Read before the Orthopedic Section of the New York Academy of Medicine, March 16, 1894.

Such suppuration, resulting in such an acute post-pharyngeal abscess, occurs as a complication or sequel of pharyngitis, tonsillitis, diphtheria, both of the streptococcus and Klebs-Loeffler variety, syphilitic and tubercular inflammation of the lymphatics of this region; and finally it may also occur as a result of suppurative inflammation of the connective tissue behind the pharynx during or after any of the acute infectious diseases, such as measles and scarlet fever. I have treated a number of such abscesses occurring several weeks after the eruption of measles. It is a peculiar fact that, while the chronic osteitic form of retro-pharyngeal abscess occurs quite frequently in adults, the acute form occurs with much greater frequency in very young children. Why this should be so is readily explicable; let us take, for instance, the abscess following tonsillitis. In adults this shows itself as a suppurating tonsillitis, known as quinsy sore throat; the pus collects either beneath the tonsil or at the immediate vicinity of the tonsil, gravitating to the lowest point it can attain, until nature or the surgeon evacuates the sac. Such patients, as a rule, will not lie down on account of the difficulty in breathing and swallowing. In a very young child, however, such purulent collections forming about the tonsil, as in the adult, also gravitate to the lowest point; but here the almost constant recumbent position of the little patient makes the back of the pharynx the lowest point, hence the more frequent occurrence of retro-pharyngeal abscess in these little subjects.

There is another form of retro-pharyngeal abscess which results from the impaction of foreign bodies, like fish-bones, in the posterior wall of the pharynx; these abscesses are properly designated as traumatic, retro-pharyngeal abscess. Thus Adams reports in the *London Lancet* of 1847 two cases of retro-pharyngeal abscess due to impaction of fish-bones in the pharynx. John Bokai, of Pesth, whose work upon this subject was published in Leipsic in 1876, reports 144 cases of retro-pharyngeal abscess in children, of which by far the larger number (129) were idiopathic in their origin, and resulted, according to him, from a lymphadenitis retro-pharyngealis. It will be readily granted, in the present state of our knowledge concerning suppurative processes, that what he considered a lymphadenitis was probably a pharyngitis or tonsillitis of the streptococcus or Klebs-Loeffler variety with pyogenic cocci.

These so-called idiopathic abscesses Bokai called primary retro-pharyngeal abscess. All others he classed as secondary. Thus, of the cases reported 3 were secondary to pus formed in other portions of the throat, and sinking to the back of the pharynx, 4 secondary to spondylitis cervicalis, 7 occurred in the course of scarlet fever, and 1 was traumatic.

Pathology.—I do not intend here to study the pathology of abscesses in general, but shall only call attention to some essential points peculiar to some of the varieties of retro-pharyngeal abscess. All of these abscesses have not a similar pathological anatomy. Indeed, it is found that the post-pharyngeal abscess occurring in cervical Pott's disease differs in very essential respects from all other forms of this disease. This form of retro-pharyngeal abscess has its seat anatomically behind the pharynx, but very important facts would be lost sight of were we satisfied with this vague localization of the pus. These abscesses, originating in the necrotic and purulent disintegration of the bodies of the vertebræ and the inter-vertebral disks, necessarily destroy the periosteal covering of the bone, so that the abscess, when it has become sufficiently prominent at the back of the pharynx to be termed a retro-pharyngeal abscess, is no longer sub-periosteal. The pus, however, does lie underneath the common ligament of the vertebral column. This ligament is a strong band of fibres extending from the body of the axis above, along the front of the bodies of vertebræ to the upper bone of the sacrum. This dense fibrous band is much more intimately adherent to the inter-vertebral disks than to the centre of the bodies of the vertebræ; it is composed of several layers

of fibres of varying length, but closely interlaced with each other. The most superficial and longest fibres extend between four or five vertebræ; a middle set of fibres extends between two or three vertebræ, and the deepest layer passes from one vertebra to the next. This peculiar arrangement gives great strength and resistance to the anterior common ligament, so that pus developing below it finds great difficulty in burrowing through. As a result we find that retro-pharyngeal abscess due to Pott's disease has the external layer at least of the anterior common ligament as an important portion of the wall of the abscess, separating it from the pharynx. Dissection of this portion of the neck shows that such abscesses have between them and the pharyngeal wall, in addition to the anterior common ligament, the so-called pre-vertebral fascia, which is an offshoot from the deep surface of the strongest fascia of the neck, namely, the deep cervical fascia. This pre-vertebral fascia passes behind the carotid vessels, of which it helps to form the posterior sheath, and behind the sterno cleido-mastoid muscles of which, together with the deep layer of the cervical fascia, it also forms the sheath. If, then, these abscesses have become large enough to break through the anterior common ligament, the pus comes to lie beneath the pre-vertebral fascia. Limited by this fascia, it gravitates to the lowest point; thus the abscess is directed by the pre-vertebral fascia behind the carotid vessels and sterno-cleido mastoid muscles, and comes to present in the posterior triangle of the neck. The pre-vertebral fascia being further continued over the brachial plexus and subclavian vessels, and finally assisting in forming the axillary sheath, the abscess directed by it may come to present even in the axillary space. We find, then, that a retro-pharyngeal abscess due to Pott's disease may be felt in the throat, or later on at the posterior triangle of the neck, or even in the axilla. It is for this reason that recent German authorities have advised the operation for the cure of post-pharyngeal abscess in general, to be performed by external incision at the posterior triangle of the neck, passing behind the carotid vessels and draining the abscess through this tract. But while this mode of operation would appear to be logical in this variety of retro-pharyngeal abscess (although even here the advisability and practicability of this method of operation is questionable), there is no logical reason why this method of operation should be adopted in any of the other forms of retro-pharyngeal abscess; for in all the other forms of this disease pus is really retro pharyngeal, lying behind the muscular wall of the pharynx and in front of the pre-vertebral fascia. This stout fascia does not restrain the pus, and these abscesses are apt to present at the pharynx and later on underneath the lower maxilla, or at any portion of the neck in front of the sterno-cleido-mastoid. Not being restrained by the anterior common ligament they can more readily come to be retro-œsophageal, breaking into the œsophagus or into the posterior mediastinal or pleural cavities.

Symptomatology and differential diagnosis. I believe that the cases I have seen, both those due to Pott's disease and those from other causes, have been characterized by difficulty in deglutition as their earliest subjective symptom. This and a peculiar nasal voice, very much resembling that characteristic of post-diphtheritic paralysis of the fauces, have been the earliest characteristic manifestations; they always call for a careful examination of the throat, both visually and by digital exploration, when positive objective signs of the difficulty will be found. The nasal voice, due obviously to the fact that the pharynx is encroached upon, is not a so-called croupy voice. It is not hoarse or barking; on the contrary, the cough is soft and excessively gurgling, owing to the collection of mucus in the pharynx and behind the nose. This gurgling is manifest not only in the cough but in breathing and speaking. If the pus be high up behind the naso-pharynx, the patient will breathe with his mouth wide open both at expiration and inspiration; if the pus be behind the glottis, the patient will have stenosis, to a greater or less extent, of the glottis, and the difficulty in breathing will not only be an inconvenience, but may be as severe as that obtained in croup. This is due not only to the pressure of the abscess upon the larynx, but to the resulting œdema of the glottis. This latter condition is owing to serous infiltration of the structures surrounding the entrance to the larynx. Generally there is a soft cough, due to the attempts to get rid of the mucus flowing into and irritating the larynx. All of these symptoms begin mildly, and increase in severity with the increase in the size of the abscess.

The principal physical signs are those obtained by digital examination of the throat; when such an abscess is suspected, an examination of the back part of the pharynx, from behind the nares above to as far as the finger can reach below, should be made. This can be done either while the patient's mouth is held open by a gag, such as that attached to the O'Dwyer intubation case, or by protecting the finger by placing the handle of a spoon transversely between the teeth. A rapid sweep of the posterior pharyngeal wall from above downward and return from below upward should be made. If an abscess be present, it will present a soft, fluctuating mass, varying from one-quarter of an inch to an inch or more in diameter. At this place one cannot feel the bony spinal column as can be felt in the other portions of the back of the throat. When such an abscess has been diagnosticated, it should be the aim of the examiner to feel for some point in the abscess rather softer than the rest of the wall, and this will show the point of election for evacuating the pus. In addition to this digital exploration of the abscess, there are other objective signs; the neck is apt to be held stiffly, not to the side, as in torticollis of Pott's disease, but rigidly, with the head in slight opisthotonos, the object being to prevent rotation of the neck. Every effort of the patient is directed toward getting as much breathing space in the back part of the pharynx as possible. The mouth is as a rule kept open, and there is dribbling of the saliva from the lips, especially in the younger patients; the lymphatics about the angle of the lower jaw are sometimes enlarged; in the later stages of the abscess there is swelling of the throat laterally, and even fluctuation can sometimes be felt externally between the angle of the lower jaw and sterno-cleido-mastoid; sometimes, in old cases of the retro-pharyngeal abscess of Pott's disease, an abscess can be felt in the posterior triangle of the neck, and in rare cases even in the axillary region. Fever is present to a slight extent in acute abscesses of this class, but is never present in the chronic abscesses, as, for instance, those of spondylitis.

The clinical discussion of this condition would be incomplete if we neglected to call attention to some of the conditions with which retro-pharyngeal abscess may be confounded. The first and most important of these is croup. It is true that patients suffering from such an abscess in an advanced stage do have difficult respiration, as shown above, but the croupy metallic cough is never present unless the abscess occurs as a complication of diphtheria or croupous laryngitis. Quinsy sore throat, while giving rise to a similar gurgling in breathing, cough, dyspnœa, and drewling from the mouth, can always be diagnosticated by the localization of the abscess on digital exploration. A tuberculous patient was for two years treated by his family physician for tuberculous laryngitis. At the time of my examination I found that the hoarseness and difficulty in swallowing were due to a slowly-developing abscess in the post-pharyngeal region, due to cervical Pott's disease; this abscess was opened externally behind the sterno-cleido-mastoid muscle and a drainage-tube inserted. It never healed, and the patient died of pulmonary tuberculosis four months after the operation. From post-diphtheritic paralysis affecting the muscles of the pharynx, soft palate, and the pillars of the fauces, this condition can be differentiated by a digital exploration: the history will sometimes aid, although frequently the paralysis is the first intimation that the patient has had diphtheria.

It is essential always to come to a positive conclusion as to whether the abscess is the result of Pott's disease of the vertebræ, for the reason stated above, namely, that these abscesses are apt, if let alone, to point externally in the manner already set forth. As to the time it takes a retro pharyngeal abscess to develop, this varies with the causation of the abscess. Abscesses due to bone disease develop, as usual, very slowly, in some cases months elapsing before the abscess gives rise to much inconvenience. On the other hand, acute abscess of this variety complicating tonsillitis or the acute infectious diseases, may develop within two or three days. Although these remarks have for their object rather a discussion of the manner of the occurrence of retro-pharyngeal abscess, I cannot refrain from saying a few words as to treatment. Bokai in his report of a hundred and forty-four cases of this disease states that all were opened through the pharynx, and he is able to report a hundred and twenty recoveries. What I have said about pathological anatomy will bear me out in the statement that these abscesses, except perhaps those due to Pott's disease, should all be evacuated through the pharynx. Of the six cases which I treated in private practice during the past year, five were evacuated through the pharynx, and one, the adult above referred to, behind the sterno-cleido-mastoid. I have not seen sepsis follow the opening of these abscesses in the pharynx. The one operated externally discharged for four months after the operation. I think the external operation should never be done unless the abscess is actually pointing externally. I cannot consider it justifiable to submit the patient to a dangerous surgical operation to reach the abscess from without, when no advantages are to be derived thereby. That the operation under these circumstances is a dangerous one in the hands of all but the most expert surgeons, is readily conceded, when it is remembered that the knife must dissect the neck in the posterior triangle, care being taken to get behind the carotid sheath, avoiding injury to the most important anatomical structures.

GAVAGE (FORCED FEEDING) IN THE TREATMENT OF ACUTE DISEASES OF INFANCY AND CHILDHOOD.

By L. EMMETT HOLT, M.D.,

NEW YORK.

PROFESSOR OF DISEASES OF CHILDREN, NEW YORK POLYCLINIC; ATTENDING PHYSICIAN TO THE BABIES' HOSPITAL, TO THE NURSERY AND CHILD'S HOSPITAL, ETC.

During the summer of 1891, in my service at the New York Infant Asylum, Dr. Charles G. Kerley, then resident physician, made quite extensive experiments in the use of gavage as a means of controlling obstinate vomiting in young infants. Dr. Kerley read a report of his cases at the meeting of the American Pediatric Society in September of that year, and published it in the transactions of the society. These experiments demonstrated to my satisfaction two things: first, that gavage was a very simple procedure, and secondly, that it was one of great value in the treatment of diseases of early life.

In November, 1891, I was attending a private patient with scarlet fever with complicating diphtheria. The case was a desperate one, with profound sepsis, hyperpyrexia and delirium, and great prostration almost from the beginning. By the fourth day nothing whatever in the shape of nourishment or stimulants could be gotten down without a struggle, and the child was being worn out by efforts that were well-nigh fruitless to get her to take even the smallest quantity of food or stimulants. At this time gavage was begun and continued throughout the rest of the illness. On account of the condition of the throat the catheter was passed through the nose, and the child was fed regularly every six hours six ounces of peptonized milk, with whiskey and digitalis. Hardly an ounce of the food was regurgitated, and the relief to the child and to the nurses was very great. Although this patient died of sepsis on the eleventh day, life was prolonged four or five days by gavage, and I think by this only.

Since that time I have rarely found it necessary to use the nose for feeding, and I believe that it will not often be required. In the following year I made a preliminary report to the Clinical Society on the subject of forced feeding in cases of severe acute illness, and at the Academy of Medicine the same year, in a discussion upon the treatment of diphtheria, I demonstrated the method of gavage before the Section in Pediatrics.

During the past two years gavage has been in daily use in three institutions with which I am connected, the Babies' Hospital, the Nursery and Child's Hospital, and the New York Infant Asylum. Our experience has now extended to observations upon upward of four hundred cases, in most of which gavage has been repeated many times. It has been tried in almost every variety of acute disease in infants and small children, and has won its place as one of the most valuable of our therapeutic measures at this time of life.

The technique of gavage is very simple. The ordinary apparatus used for stomach-washing is all that is required, viz., a funnel, eighteen inches of rubber tubing, a soft rubber catheter, and a few inches of glass tubing for connection. The catheter should have a double eye. No. 14, American scale, is the best size for infants under six months, and about No. 17 for older children. A four-ounce funnel is large enough for infants, while for older children it is an advantage to use one holding six or eight ounces. The child is placed flat upon the back in its crib, and the head steadied by an assistant. The tongue is depressed with the left forefinger, and the catheter, previously oiled, is pushed rapidly down the pharynx until nine or ten inches have passed the lips. The funnel is now raised high in the air for a few moments to allow gas from the stomach to escape. The food is poured into the funnel and rapidly runs into the stomach. As the last of the food leaves the funnel the catheter is tightly pinched and quickly withdrawn. This last step is an important one in order to prevent trickling of food in the pharynx, which may provoke vomiting. Sometimes the food remains in the funnel, and will not run into the stomach. This is not ordinarily from blocking the eye of the catheter by mucus, but from gas in the tube. In a few moments this generally rises to the surface of the liquid, and then the food flows readily. If regurgitation of the food takes place it is generally immediately after withdrawing the tube. In many cases it may be prevented by allowing the gas to escape from the stomach before putting the food in, and in others by holding the jaws separated for a few moments after the catheter has been withdrawn.

In young infants no gag is required, but in older children one is quite necessary, since otherwise they may bite the catheter in two. Where a gag is needed the ordinary one accompanying intubation sets will answer the purpose. Two assistants are usually required to feed an older child. It is important that the child should be held flat upon its back.

The time consumed in feeding by gavage is from ten to thirty seconds. In infants this is very easily done. In the institutions referred to all the nurses have been taught to do it, and they learn with very little experience to do it very quickly.

The uses of gavage may be briefly stated as follows:

1. In premature infants its value has been well established on the continent of Europe, in connection with the use of the incubator. As yet we have had but little experience with it in this country.

2. It is useful in controlling persistent vomiting in very young infants where the vomiting occurs partly from habit and partly from exaggerated pharyngeal reflex. Dr. Kerley's published paper established this point conclusively, and subsequent experience has confirmed his observations. Dr. R. B. Kimball, attending physician to the Summer Branch of the Babies' Hospital, is soon to publish a large number of cases treated in the

summer of 1893, also confirmatory of this point. I will not enlarge upon it.

3. In acute diseases where for any reason children refuse all food, or struggle violently against everything that is offered them. In very many cases of severe illness in children from two to five years of age, the point is reached, after four or five days have passed, when the child absolutely refuses to take anything, and nothing is gotten down excepting by holding the nose. This is, to my mind, one of the most promising fields for the application of gavage. In very severe cases of scarlet fever, diphtheria, broncho-pneumonia, typhoid, and empyema just this necessity is felt.

4. In serious brain disease where the patient cannot be fed by ordinary means. This may occur in tubercular meningitis, chronic meningitis, and in many other diseases where delirium or coma is a symptom. Life is not only prolonged but existence made more tolerable, and the patient is much more easily cared for by the attendants.

A few illustrative cases will serve as types of many: A child, aged three, with chronic meningitis, was fed for six weeks by gavage; by no other means could anything be gotten down excepting by the expenditure of a great deal of time, struggling, and holding the nose.

A child, aged two, with empyema and very marked asthenic symptoms, after two weeks' illness absolutely refused everything in the way of nourishment, and was in danger of dying from inanition. For two weeks all food was given by gavage, at the end of which time the child was able and willing to drink its milk from a cup, and take stimulants without difficulty.

A private patient, aged twenty months, with double pneumonia and very marked prostration, had reached the point, by the tenth day, when almost nothing could be done in the way of nutrition. After gavage for two days the temperature gradually fell, the patient was able to take food naturally, and made an excellent recovery.

In a recent case of tubercular meningitis seen in consultation in private practice—the case was hopeless for five days before death—all the food was given by gavage. After the case closed, the attending physician said, "You have no idea what a comfort the gavage was to the family." This was especially noticeable after the struggles to give food which had preceded its use.

A recent case of diphtheria in private practice in a little girl aged five affords a striking illustration of the benefit of this means of treatment. The patient was delirious, profoundly septic, temperature 105° F. and over for a week; pharynx, tonsils, uvula, palate, and part of the mucous membrane of the mouth covered by pseudo-membrane. In the words of Dr. O'Dwyer, who saw the case, "the symptoms were about as bad as they could be." After the fifth day, to give either food or stimulants by ordinary means was absolutely impossible. She was being worn out with the constant teasing and forcing. Even at the risk of heart failure three nurses held her while I employed gavage for the first time. Not more than three ounces of food had been gotten down in the course of the previous twelve hours. Four ounces of food and one ounce of brandy with digitalis were given without difficulty, and with but little more disturbance than was necessary to make the child swallow a tablespoonful. From this time on gavage was practised regularly every six hours; the amount of food was gradually increased until eight ounces at a time were given at once. This was kept up for a week; not once was the food regurgitated, and the case made a complete recovery. In my own opinion the life of the patient was saved by this means.

To cite further cases is unnecessary, enough has already been said to show that gavage is easy, simple, and free from danger, and a very great resource in these very difficult cases.

In the adult when food is refused by the stomach we may have recourse to rectal alimentation, but in little children this is extremely unsatisfactory, and in most cases is an entire failure. As compared with holding the nose, and forcing the child to swallow, anyone who has seen the two things done will, I think, have little difficulty in deciding which is easier.

In most of the cases to which I have referred the food given has been completely peptonized milk, diluted according to the age of the child; but for infants our hospital milk and cream mixture in proportions suitable to the child's age. Stimulants, medicine, everything that is to be given may be poured in at once.

In older children where six or eight ounces at a time are given, gavage need not be repeated more than once in five or six hours. In infants the intervals should be one hour longer than the customary interval of feeding.

Stomach washing is required in conjunction with gavage in most cases in infants; once at least every day the stomach should be washed before feeding.

In conclusion I can only say to those who are unfamiliar with this therapeutic measure that a careful trial will convince anyone of its very great value.

Clinical Department.

PYÆMIA COMPLICATING TYPHOID FEVER, AND PHLEBITIS FOLLOWING PNEUMONIA.

By ROBERT L. NOURSE, M.D.,

ASHLAND, WIS.

The above-named complication of typhoid and sequelæ of pneumonia are, I believe, sufficiently rare to justify my recording the following cases, recently occurring in my practice:

Case I.—Annie D——, aged nine, of Norwegian parentage. Previous health fair, though she is a thin and anæmic child. Was taken sick October 31st with typhoid fever. (Her mother was then convalescing from the same disease.) This pursued the usual course of a case of typhoid of average severity until the stage of decline was reached, about the middle of the fourth week, when, instead of the temperature becoming normal and ushering in convalescence, it became irregularly progressive, fluctuating from day to day from 100° to 104° F., with accompanying rigors and alternating profuse perspiration. In a few days she complained of pain over the left hip, and on examination I found a deeply-seated swelling, which soon proved to be an abscess, originating from beneath the gluteus maximus muscle. A few days subsequent to this another abscess, the size of a hen's egg, was found on posterior surface of the left leg, at the lower angle of the popliteal space. These were both opened. At the same time a third abscess appeared on the left side of the nose, just above the alæ, which seemed to perforate the nose and communicate with an ulcer on the inner side. Three days later a fourth abscess made its appearance on the right shoulder, anterior surface. This was also about the size of a hen's egg. Ten days later a fifth abscess appeared on the lumbar region of the back. This opened spontaneously, much to the child's delight. After this she made a slow but uninterrupted recovery. Sulphide of calcium seemed to exert no influence over the suppurative process in this case, as, indeed, I have yet to see a case of any description in which it did have any perceptible effect. Murchison, quoted by James H. Hutchinson in Pepper's "System of Medicine," vol. i., page 294, says: "Pyæmia is an occasional complication of typhoid fever." But the latter authority says it is certainly rare in this country. Tonics and nutritious diet was the treatment.

Case II.—Mrs. S——, aged thirty two; American; married, mother of six children; was taken sick December 10th with la grippe. A week later, on being exposed, had a chill, which ushered in a lobar pneumonia of the left lung. This was complicated with considerable pleurisy, which caused a great deal of pain.

Convalescing was somewhat delayed owing to an extension of the pneumonic process, and consequent debility resulting therefrom. But when finally given permis-

sion to sit up for a couple of hours, she unwisely stood up and walked about, being on her feet considerably the first day. That night the left leg began to swell, and to be exceedingly painful and sensitive to touch. Neuralgic pains darted along the entire length of limb and into the groin and back. The following day a swelling one inch by one and a half or two inches in size could be felt over the internal saphenous vein, an inch below its exit from the saphenous opening on the inner surface of the thigh. A similar bunch could be felt in the left groin just above Poupart's ligament. These were excessively tender to touch, as, indeed, was the vein throughout its entire length.

The swelling on the thigh became slightly discolored, being of a brown or coppery hue. The vein from the groin to the popliteal space could be felt as a hard, round cord, considerably enlarged, and which rolled beneath the skin when attempt was made to grasp it between the fingers. Considerable swelling of the whole leg, but particularly below the knee, and later œdema occurred. Rest in bed, opium internally to control the pain, a strip of belladonna plaster over the tumor, and hot fomentations to the entire leg, constituted the treatment. The trouble subsided to a great extent in three weeks, though the induration and occlusion of the vein still persists; collateral circulation and reduction of swelling being greatly aided by elevation of the limb, and later an elastic bandage. Nonat claims to have immediately arrested phlebitis following typhoid fever by the application of fly-blisters along the course of the nerve.

This patient tells me she has been troubled with varicose veins of both limbs during each of her pregnancies, and once had phlegmasia alba dolens.

This case emphasizes the necessity of warning those patients who have had varicosities against a too abrupt getting upon their feet after debilitating diseases.

February 28, 1894.

DEPRESSED FRACTURE OF SKULL—SIMPLE FRACTURE OF SKULL—FRACTURE OF THE RADIUS—RECOVERY.

By DILLON J. SPOTSWOOD, M.D.,

FAIRFORD, ALA.

As all cases of brain surgery are interesting, it will probably not be amiss to relate briefly a case of depressed fracture of the skull, and fracture of the middle of the shaft of the radius.

Bryant F——, colored, aged twenty-two, a healthy laborer employed in the Sea Board Lumber Co.'s dry kiln, on January 6th was assisting his fellow-workmen in raising the kiln door, an immense wooden structure weighing a ton or two. This door is lifted by means of a windlass and chain. For some reason the windlass became unmanageable, the men releasing their hold after having raised the door some distance. The crank, or handle, revolving with great rapidity, struck F—— upon the upper right portion of the forehead and left forearm, with the results above mentioned.

The fracture was situated on the frontal bone, one and a half inch above the right external angular process, two and a half inches from right external auditory meatus, the upper edge of fracture running into the coronal suture. The fragment of bone was tightly wedged beneath the parietal bone and dura mater. The fracture was irregularly quadrilateral, one and a half inch long by one and a half inch wide, with a simple fracture running from the lower left inferior angle of depressed fracture to the superciliary ridge.

The man walked from the kiln to my office, a distance of one-eighth mile, finding me absent. Upon my return I found the man quietly seated, waiting. When questioned, he said that he had hurt his head and arm, but complained more of the arm. He was placed upon the sofa in recumbent position, head elevated. As his pulse was quite weak, a half-ounce of whiskey was administered. Forty-five minutes after the accident he had a very hard general convulsion, all of the muscles of the body twitching violently, with marked opisthotonos. Believing that an immediate operation was necessary, chloroform was administered to relieve convulsions, and the patient was sent to the company hospital.[1]

As my colleague, Dr. F. A. Webb, was absent, the operation of trephining was performed with the assistance of a druggist, who administered the anæsthetic, and the hospital nurse, who sponged, etc.

One-fourth of the head, around the injury, was shaved, washed first with alcohol, then with bichloride of mercury, 1 to 1,000; the remainder of the head was washed, and then saturated with bichloride, 1 to 2,000. Warm bichloride towels covered every portion of the head except where the incisions were to be made.

Chloroform (Squibb's) was used, which gave not the least trouble, the patient's pulse and respiration being excellent throughout the operation.

In administering chloroform it will be found that a hypodermic injection of morphia, gr. $\frac{1}{4}$ and atropia sulph., $\frac{1}{150}$, a half-hour before, always maintains the heart and respiration during chloroform anæsthesia. Ammon. aromat. spirit. ʒ j., should also be given by the mouth. The stomach should contain no food, and the head should be exactly on a level or a little lower than the body. These facts, of course, do not bear directly upon the subject; but as this method has been used in many of the operations witnessed by me, and in my own, I have described it.

An incision three inches in length, running horizontally from about one inch to the right and above the fracture, to a point three inches and a half above the inner extremity of the superciliary ridge, was made; another incision, joining the first at the last-named point, was made two and a half inches directly downward upon the forehead, making a triangular flap. Hemorrhage was controlled by digital pressure upon the edges of the flap, and it was not found necessary to tie a single vessel. The exposure of the skull revealed the depressed and simple fracture which have been described. The periosteum was removed from a space large enough to accommodate the trephine, at the upper left angle of fracture, which was near the middle of the upper portion of the frontal bone. The periosteum was also removed from the edges of the fracture, all around, for about an eighth of an inch. The removal of the fragment of bone exposed a large clot upon the dura mater. This having been removed, the sharp projections of bone were removed carefully by bone forceps. The dura mater was found to be slightly contused, this membrane and the edges of the bone were thoroughly cleansed with sterilized water.

A half-dozen of pieces of large antiseptic catgut were used for drainage, their points of exit being the upper right and lower left angles of the triangle (diagonally downward). The scalp incisions were closed with catgut sutures. The whole surface was now carefully washed with hot bichloride solution, 1 to 2,000, and the usual antiseptic dressing applied.

Union by the first intention was the result, the catgut sutures and drainage being perfectly absorbed.

On the morning of the second day his temperature was 102° F. Sulph. magnes., ℥ j., in lemonade, opened the bowels well. Antipyrine, gr. viij., sodii bromidi, gr. xx., liquor ammonii acetatis, ʒ iv., every two hours, were given, until fever and headache were relieved. No bad symptoms appeared after the third day. Liquid diet was kept up for five days.

Dr. Richard Förster, Professor of Ophthalmology in the University of Breslau, has been named a life member of the Prussian House of Lords.

[1] [The Sea Board Manufacturing Company's mills, near Mobile, at Fairford, Ala., a very large industry, employing seven hundred to one thousand men, having its own physicians and hospital.]

Progress of Medical Science.

Recent Observations on Cystitis.—Dr. Barlow's experimental researches would seem to show that in the case of rabbits, retention of urine, caused by ligature of the urethra, causes suppuration in the latter, but that sections of the freshly hardened bladders of the animals experimented on did not show the least signs of inflammation. Nine cases of cystitis are described. In each of seven cases the urine contained pure cultivations of some one particular microbe, which in five out of the seven was found to be Escherich's bacterium coli commune, while in the sixth and seventh cases the germ, which, furthermore, possessed the property of decomposing urea, was identified as the staphylococcus pyogenes albus. On introducing aqueous suspensions of pure cultivations of these germs into the bladders of rabbits and dogs, Barlow found that the simple injection of bacilli coli commune sufficed to produce cystitis, though the affection could be more readily induced when the injection was supplemented by ligature of the urethra; the staphylococci albi of Case VI., however, proved non-pathogenic, but those of Case VII. were capable of producing cystitis, either with or without the application of the ligature, and that the malady set in before ammoniacal decomposition of the urine was established. Dr. Barlow concludes that such bacteria as possess pathogenic properties for the bladder are capable of producing inflammation when that organ is intact, and that the so called accessory causes render the action of the germs more intense. Decomposition of the urea is necessary for the production of cystitis. With regard to gonorrhœal cystitis, which is, as a rule, not looked upon as a product of the gonococcus, Barlow's observations led him to the conclusion that there is a very rare form of cystitis brought about by the gonococci alone. Catheters may be sterilized in steam in thirty-five to forty minutes; the same result may be produced in fifteen minutes with nitrate of silver solution, 1 to 1,000; or in thirty minutes with corrosive sublimate of the same strength, provided the catheters are first of all coated with sterilized glycerine, and that the bore of the instrument is also syringed out. Patients who are compelled to catheterize themselves should pay attention to the following rules: The syringe should always be kept in a vessel half filled with a solution of nitrate of silver, 1 to 1,000, the catheter in a metal basin. There should also be kept handy two vessels, the one containing nitrate of silver, 1 to 1,000, and the other a three per cent. solution of boracic acid. Before using the catheter it should be syringed out three times with the nitrate of silver solution, then immersed in that solution for from fifteen to twenty minutes, and finally rinsed in boracic acid, and the external genitals, especially the orificium urethræ and the parts around it, be cleansed with the silver solution. The glycerine should be kept in a flask, so that it can be boiled frequently. After micturition, the catheter to be thoroughly washed and syringed with water, also with the boracic acid and silver solutions, and finally rolled up in blotting-paper and put away in the metal box. Apart from cystitis of tubercular or gonorrhœal origin, the treatment of inflammation of the bladder should be directed toward rendering any bacteria in that organ innocuous, at the same time taking care not to neglect such matters as the retention or decomposition of the urine. Little can be expected from the internal administration of drugs, except in cases of ammoniacal decomposition of the urine, in which temporary alleviation may best be obtained by salol. The most rational method of arresting the development of the pathogenic micro-organism of cystitis is by the instillation into the posterior portion of the urethra and the bladder some twenty to thirty drops of a 1 in 5,000 solution of corrosive sublimate after micturition, gradually increasing the strength to 1 in 1,000, but never injecting more than from thirty to sixty minims. A two to five per cent. solution of nitrate of silver may also be used, but not in cases of tubercular cystitis in which corrosive sublimate acts as a palliative.—*Archiv für Dermatologie.*

Intermittent Nephrydrosis.—At a recent meeting of the Paris Société de Chirurgie, M. Tuffier remarked that three points had to be studied in the consideration of intermittent nephrydrosis—namely, the etiology and pathogeny, the pathological anatomy, and the treatment. It seemed to him certain that the affection was almost always directly connected with a movable kidney. Facts sustained this, for it was almost invariably met with in women and nearly always affected the right kidney. The mechanism was that which had been maintained by Landau. M. Tuffier had come to a realization of it experimentally. In eight dogs he had rendered the kidney movable, and had then fixed it in an abnormal situation; in four instances nephrydrosis had been the result, and this proportion was about the same as was observed clinically. This nephrydrosis was accompanied by the formation of a sharp bend in the ureter at the point where it crossed the vessels, about two-thirds of an inch below the hilum of the kidney. Simple compression of the kidney was sufficient to cause the urine to overcome the impediment offered by this bend. The bend could be straightened out, and the nephrydrosis would then disappear at once. Anatomical facts observed in the course of operation also spoke in favor of the same mechanism. In two patients the speaker had distinctly observed the bend in the course of an operation, and in a third patient he had observed, at a point about an inch below the hilum, a sudden change of calibre in the ureter, indicating that there had been a folding at that point. This bend could be made to disappear by a change in the attitude of the person; one of the attachés of the Hôpital Beaujon, who had a movable kidney, perceived that her flank increased in volume and became painful when she remained standing, but that as soon as she lay down and raised her hips decidedly the swelling disappeared, and she felt herself relieved and passed water copiously. Experiments showed, the speaker went on to say, that when the kidney was lowered, at first there was formed, not a sharp bend, but a curvature, and this curvature was sufficient to diminish the flow of urine. At the same time intense renal congestion took place, and the kidney underwent a change of shape. Two types of such change were met with: sometimes the organ took the form of a horseshoe, at other times it was flattened. As for the phenomenon of intermittence, there were two ways in which it could be explained: The bend might be straightened out spontaneously by virtue of the mobility of the kidney; in other cases the tension of the kidney might overcome the impediment and result in the expulsion of the urine. Preference should be given to the operation of fixation of the kidney. The author had practised this in nine cases with success.—*New York Medical Journal.*

Gastro-intestinal Septicæmia of Infants.—From a careful study of a series of twenty-one cases, Dr. Fischl comes to the conclusion that the acute gastro intestinal catarrh so fatal to infants in foundling asylums, etc., is in reality a manifestation of a form of septicæmia. In ten cases examined bacteriologically he found, alike in those in which there was distinct gastro-enteritis and in those in which there was obvious septicæmia, pyogenic organisms; in seven the staphylococcus pyogenes albus, in one the staphylococcus pyogenes aureus also, and in two the streptococcus pyogenes. The organisms were found most constantly in the lungs; the next most common seat was the spleen; and after these the liver and kidneys. The naked-eye changes in the gastro-intestinal canal were often slight, but in some there was great hyperæmia; the number of micro-organisms in the canal was small, and they were situated chiefly in the superficial parts of the epithelium. The kidneys showed frequently parenchymatous inflammation, hemorrhages, and miliary abscess about accumulations of micrococci. Fischl suggests that the organs primarily infected are the lungs.—*Berliner klinische Wochenschrift.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., 43, 45, & 47 East Tenth Street

New York, April 28, 1894.

THE LANGUAGE OF INTERNATIONAL CONGRESSES.

As each International Congress takes place, the inconveniences resulting from the Babel of tongues become more and more apparent. Many physicians are able to understand the written word in one or two languages besides their own, and think they will have no difficulty in listening to papers read in those same languages, forgetting that there are four arts in linguistic science, namely, reading, hearing, speaking, and writing, and that the possession of one of these arts by no means implies that of the others. It is comparatively easy to acquire the art of reading a language by one's self, but that of hearing—by which we mean the ability to understand and grasp the meaning of the spoken word or phrase—is something that is acquired only by long practice and training of the ear. And thus it is that the man who is able to read a scientific treatise, in German, for example, with perfect ease, is utterly at sea when the same treatise is read *to* him instead of *by* him. The words, as they are uttered, have no meaning to him and are merely inarticulate sounds in his ear. He reads a paper, let us suppose, in his own language. It is one which he, at least, believes embodies new truths which he is anxious that the medical world shall know and appreciate. He sees many of his auditors go out of the room during the reading, others nodding, or perusing the official journal of the Congress, and then, when the discussion of his paper comes he doesn't understand what objections are raised, and consequently cannot reply to them.

This difficulty was even greater at the Rome Congress, where there were four official languages instead of the usual three. Italian is too insignificant a language for a busy man to learn, yet it was the predominant language at that meeting. More than one-half of the members of the Rome Congress were Italians, and ninety-five per cent. of them spoke no language but their own. Many of those from other countries than France and Germany read their papers in French, but their foreign accent was so marked that no one but a born Frenchman could understand them.

Is there no remedy for this barrier to intercourse between men of science? Is it insurmountable? We fear the solution will not be seen in our day, yet the time must come when this condition of affairs will be recognized as intolerable, and when it is so recognized and felt the remedy will be forthcoming. The only remedy is the adoption of an international language. But what language? English is, and is destined to become still more, the leading language of the civilized world, but of its general adoption by international scientific bodies we have little hope. French and German are equally out of the question. There remain Latin and Greek. The former might do as a written language for scientific treatises, but in the form in which it has come down to us, a literary language pure and simple, it is too unwieldy for verbal use. It is a dead language, and too long dead ever to be resurrected. But Greek, on the other hand, is not dead. It is a living language, flexible, and perfectly adapted to all the needs of human intercourse. Modern Greek is a beautiful tongue, easily learned, and lends itself to every form of verbal and literary expression. It is the language of a small nation, and consequently no national jealousies would stand in the way of its adoption by a congress of all nations.

We have before suggested the adoption of this language, and our suggestion has been adopted and enlarged upon by others. Among them is Dr. Rose, of this city, who has recently published a pamphlet upon the subject which we would commend to the consideration of our readers. In it he shows that the alleged difficulty of acquiring Modern Greek is exaggerated, this exaggeration being due in great part to the absurd method by which the ancient language is taught in our preparatory schools and colleges—a method which would render the acquisition of any language an almost impossible task. If one-quarter of the time now wasted in classical Greek, which differs very little from the Greek spoken and written to-day in Athens, were devoted to the teaching by a rational method of the modern tongue, every school-boy would not only be able to speak Greek fluently and correctly, but also to read Homer and Xenophon as easily as the college student now reads Shakespeare and Chaucer.

We say again, we have little hope that this suggestion will be adopted in the near future, but we are confident that when the absolute necessity of some common international language shall come to be recognized, it will be Modern Greek in preference to all others that will be adopted. In the interests of science we would that that day might come soon.

THE ELMIRA REFORMATORY.

AT the time of the report upon the Elmira Reformatory we expressed surprise that an institution which had heretofore been held in such esteem should be credited with such serious abuses. We referred also to some of the facts bearing on the other side, and presented by the Board of Managers. We are in receipt of a memorial of the Board of Managers relating to the recent investigation by the State Board of Charities, in which the case for the Managers is most forcibly presented.

As a result of this memorial and of other influences, Governor Flower has appointed the Hon. William L. Learned, of Albany, Dr. Austin Flint, of New York, and the Hon. Israel T. Deyo, of Binghamton, commissioners to take testimony and conduct the examination of witnesses as to the truth of the charges.

We trust that, as a result of this investigation, the exact

truth will be learned and justice done. It is unfortunate that the fortunes of the Reformatory should be mixed up with newspaper rivalry and politics, yet such is the case.

We believe it only justice to place on record the following remarks as to the physician in charge of the Reformatory. The memorial says:

"The committeeman, in his excessive desire to malign the institution it was his duty simply to investigate, animadverts upon the fact that the Reformatory physician is the son of the president of the Board of Managers. His capacity or ability is not brought in question. The report admits that the physician, Dr. Hamilton D. Wey, devotes each forenoon, from eight until twelve or one o'clock, and the testimony shows sometimes until two or three, to the duties belonging to his office. It nowhere pretends that he is inexperienced, careless, or inefficient. The testimony proves that he has given in every case prompt and conscientious attention to the sick; he has inspected the quantity and quality of the food; he supervises the sanitary condition of all parts of the institution; and not a single instance of unprofessional conduct has ever been proven against the Reformatory physician.

"He alone has put into shape and use the gymnasium, and the physical training and culture now in vogue in the institution. He is, upon all questions of prison health and reform, and upon all topics that relate to the betterment of the physical training and the condition of its inmates, a man of national repute and standing. In all penological congresses, in all assemblies where men of experience meet to discuss improvements in prison conduct and discipline, Dr. Hamilton D. Wey is a justly acknowledged authority."

A DIRTY CITY.

The Women's Health Protective Association of Pittsburgh, Pa., is making an effort to improve the sanitary condition of the city by organizing a municipal system for the removal of garbage. At present all refuse is removed by private companies, or not at all. The poorer classes cannot and do not remove refuse, and it simply accumulates. Alleghany City has the highest death-rate in the country from typhoid fever, and Pittsburgh is a close second. This is not a surprising condition in towns where decaying matter is allowed to accumulate. It is extraordinary that any city in a civilized country should tolerate such a condition. Yet we learn that the Pittsburgh Council has just rejected a plan for the systematic removal of its garbage. Some communities are so stupid that they require the visitation of an epidemic in order to educate them to even the most ordinary knowledge of the value of municipal hygiene.

The *Pittsburgh Medical Review* editorially states that one of Alleghany's philanthropic select councilmen proposes to present a drinking fountain to that fair city. As all well-regulated fountains should have an inscription, the *Review* suggests the following:

"Erected to the memory of one hundred and sixty-one citizens who drank of this water and died of typhoid fever during the year 1893. This water is warranted to be drawn from the Alleghany River, at a point where the discharges of eighteen sewers of Pittsburgh are mingled with the stream, and that each drop contains on an average two hundred bacteria."

A HEALTHY LOCALITY.

The St. Paul-Minneapolis combination beats the world in the matter of vital statistics. While the mortality-rate in New York is 26.47, in London 17.11, in Chicago 18.95, and in nearly all large cities ranges from 17.0 to 26.0, it is only 9.61 and 9.60 in St. Paul and Minneapolis. We congratulate Minneapolis on the .01 per 1,000 advantage which it shows over its rival, and we extend to both cities our congratulations upon their superlative salubrity. We are "Yours for Health." But how about the doctors? If these towns have nearly one-third less mortality, there should be a correspondingly less amount of sickness. One death represents about twenty-five cases of sickness, and hence a death-rate of 9.60 per 1,000 would mean that in Minneapolis there are only 25,000 cases of sickness annually as against 600,000 in New York City. Now, if New York had only the death-rate of Minneapolis, a city of 209,000 inhabitants, its total sickness would be only about 225,000 annually. Yet the proportion of doctors in Minneapolis is nearly the same as that of New York, and the question arises, how do they live? Perhaps the people of these great Western cities are of the kind that get ill but never die—a most desirable class from a medico-economic point of view. At any rate the morbidity-rate of Minnesota would be an interesting thing to know. The *Northwestern Lancet* explains the healthfulness of its environment thus:

"The drainage is perfect, the water-supply abundant and of the best, malaria is unknown; phthisis and other diseases that fasten upon particular localities are rarely found here, except as importations; zymotic diseases, when they occur, are, as a rule, of mild type, the malignant forms appearing but rarely; and the worst features of the climate, that is its extremes of heat and cold, are more trying to the nervous system than injurious to the general vitality. In fact, the only diseases that prevail here to an average extent are those with which climate has little to do, such as the diarrhœal diseases of children, cancer, the accidents of childbed, and the like.

News of the Week.

Registration of Births and Marriages.—A resolution condemning the bill now before the Senate fixing the penalty at $100 and imprisonment for a failure to report marriages and births within ten days, was offered by Dr. Daniel Lewis, at the last meeting of the County Medical Society. The resolution was adopted.

Provost Pepper Resigns.—At a special meeting of the trustees of the University of Pennsylvania, held April 23d, Dr. William Pepper resigned his position as provost. This action was taken in opposition to earnest entreaties, and from his feeling that the great growth of the university during his administration has reached a place where it demanded the undivided efforts of the provost. He will continue to hold the Professorship of Medicine, and will devote himself more especially to the interests of the medical school and hospital. At the same meeting Dr. Pepper made a contribution of $50,000, which will be applied to the extension of the hospital buildings. His gifts to all departments have been many and large. The University of Pennsylvania, during the thirteen years of

his administration, has increased in the teaching force from 88 to 268, and in students from 981 to 2,180. About $4,000,000 has been added to the value of the lands, buildings, and endowments. The acquisitions during the current year will amount to $1,000,000.

Professor W. H. Welch.—Our city readers are reminded that Professor Welch, of Johns Hopkins University, will deliver the Middleton Goldsmith Lecture before the New York Academy of Medicine, on this Saturday evening, at 8.30. The subject is "Mixed and Secondary Infections."

Reconstruction of Navy Hospital at Brooklyn, N. Y.—Surgeon-General Tryon has secured in the annual Naval Appropriation Bill, provision for the use of a large sum of money derived from the sale of the Navy Yard lands to the city of Brooklyn, which he will utilize in improving the Navy Hospital at Brooklyn. One of the most important additions will be the construction of an operating amphitheatre with all modern appliances. Two wards of modern design, one on each side of the present main building, are to be erected, of sufficient size to accommodate one hundred men. The building for these wards will be one story in height, with suitable elevation, and built of the same material as the present building. Roadways and walks are to be laid out around the hospital, and the grounds placed in an attractive condition.

Death of Dr. Joseph Workman.—Dr. Joseph Workman, for a quarter of a century superintendent of the Toronto Asylum for the Insane, and the first president of the Ontario Medical Council, died on April 15th in Toronto, Ont., aged eighty-nine years. Dr. Workman was a well-known and valued contributor to medical literature. He had made himself especially familiar with the works of Italian alienists.

Dr. David Crary, Sr., probably the oldest physician in Connecticut, died of old age on April 16th, in Hartford, Conn. He was born in Wellingford, Vt., April 18, 1806, and he practised medicine there and in Hartford for more than fifty years. He was present at the first administration of ether by Dr. Horace Wells, the discoverer of anæsthetics. He also performed the first operation for tracheotomy in Hartford. Dr. Crary was graduated from the medical college at Castleton, Vt., in 1834. He was a member of the Hartford County Medical Society and the Connecticut Medical Society. He was a noted fox-hunter.

Commencement Exercises of the Western Pennsylvania Medical College.—The Commencement exercises of the Western Pennsylvania Medical College, Medical Department of the University of Western Pennsylvania, were held Thursday, March 22d. Fifty-seven graduates received the degree of Doctor in Medicine.

Congress of American Physicians.—Although our cable reports have given us full details of the papers that were read at the International Medical Congress at Rome, yet it would seem as if the approaching Congress of American Physicians and Surgeons need not fear a comparison when such subjects as the following are to be presented: "Morphology as a Factor in the Study of Disease;" "Sewer Gas: its Bacteriology: as a Cause of Disease;" "The Distribution and Control of Leprosy in the United States; the Distribution; the Prophylaxis and Treatment;" "Nephritis in its Surgical Aspects; the Bacteriology of Nephritis;" "The Conservative Surgery of the Female Pelvic Organs;" "The Surgery of the Accessory Sinuses of the Nose;" "The Influence of Infectious Processes on the Nervous System; Pathology and Etiology; the Relation to General Nervous Diseases; the Relation to Mental Disease; and the Therapeutics."

Nor when the list of physicians who are to take part in the discussion is perused need we feel ashamed as a nation.

Annual Dinner of the Alumni Association of the New York Hospital.—The second annual dinner of the Alumni Association of the New York Hospital was held on Monday evening, April 23d, at Hotel Marlborough. Dr. Charles T. Poore, President of the Association, acted as toast-master. Speeches were made by Drs. Shrady, Culver, Davis, Weir, Amidon, Delavan, Baylies, Adams, Higgins, and Richards, the exercises closing with music and singing by Drs. Barstow and Conner.

The D. Hayes Agnew Memorial.—The State Legislature, at its last session, made an appropriation of $80,000 to the Pennsylvania University Hospital for building purposes, provided that an equal sum of $80,000 be raised by the friends of the hospital, and paid in cash, available for construction purposes. The managers of the hospital, appreciating the eminent propriety of the movement, have consented to give to the entire wing the honored name of D. Hayes Agnew.

Toward the additional $80,000 to be so raised, about $60,000 can now be counted upon as available in cash on or before May 1, 1894, leaving only about $20,000 more to be secured by that time, so that building operations may begin this spring, and the State appropriation be drawn and expended within the two years contemplated in the act.

It is to be hoped that, in addition to the building fund, there may also be secured a sum sufficient for the beginning of an endowment.

All those who desire to join in this memorial can do so by sending their subscriptions to the treasurer, Mr. Eugene Delano, of Messrs. Brown Brothers, at the banking-house, southeast corner of Fourth and Chestnut Streets, Philadelphia.

District Medical Society, Union County, N. J.—At the annual meeting of the District Medical Society of the County of Union the following gentlemen were elected: *President*, Norton L. Wilson, Elizabeth; *Vice-President*, Walter E. Clodek, Rahway; *Secretary*, E. B. Grier; *Treasurer*, F. Westcott, Scotch Plains.

Passaic County Medical Society. — The Passaic County Medical Society, on Tuesday, April 24th, celebrated its fiftieth anniversary of organization. Dr. Alexander W. Rogers delivered an historical address. The meeting was largely attended by the members and their friends.

Organization of the Anti-vaccinationists.—An Anti-compulsory Vaccination League has been organized in Brooklyn with the following officers: Dr. H. Hitchcock, *President;* Dr. Alice Campbell, *Vice-President;* and E. C. Townsend, *Secretary*. The league demands the repeal of the laws and ordinances, State and local, com-

pelling people to submit to vaccination, and also demanding equal recognition for the homœopathic method of "varioline" treatment with that of the regular vaccination.

Typhoid Epidemic in Windsor, Vt.—An epidemic of typhoid fever prevails at Windsor, Vt. About 130 cases have been reported, or 1 to every 14 of the population. Twelve have died. The State Board of Health attributes the epidemic to washings and sewage from a farm-house polluting the source of the public water supply.

Daniel E. Marston, M.D., died in Monmouth, Me., April 14th, aged fifty-eight. He graduated from Bowdoin in 1859, and served in the army during the rebellion.

Chicago has had typhoid fever, the World's Fair, William T. Stead, and now it is suffering from small-pox.

Commercial Pepsins.—A Russian physician, Dr. P. N. Konovaloff, has examined thirteen kinds of pepsin of the trade, and is convinced that there is not one of really good quality. Dr. K. thinks that the best thing is the pure gastric juice of the dog. We presume that Konovaloff's observations apply to European products alone.

The Work of the Laboratory in Germany speedily becomes a marketable product. Already the diphtheria antitoxine solution of Behring is advertised for sale, with the announcement that it confers immunity against diphtheria.

United States Quarantine Physicians for European Ports.—The detail of surgeons from the Marine Hospital Service for duty at European ports during the coming summer has been made. Three of the appointments are the same as last year: Dr. Woodward to Hamburg, Dr. Stimpson to Rotterdam, and Dr. Brown to Havre. The other appointments are as follows: Dr. Magruder to Naples, Dr. Perry to Genoa, Dr. Vaughn to Bremen, Dr. Carmichar to Antwerp.

The Rhode Island Anti-vaccination Bill.—The Anti-vaccination Bill before the Rhode Island Legislature came dangerously near being passed by the House last week. Although a bill carrying such a menace to the public health was under consideration, there was such a disgraceful apathy on the part of the legislators that the House was obliged to sit for four hours with locked doors to compel the attendance of members. After a bitter discussion, the bill was finally lost on the deciding vote of the speaker. That such a proceeding could have occurred in a civilized community in the year 1894, is not a fact to be passed over lightly. If anything marks the true advance of a community toward a higher plane of social enlightenment, it is the attention which such a community pays to questions of public sanitation and hygiene. The average community is not overprotected by proper and sensible statutes regarding public health; but if there is one such, it is beyond question the enforcement of vaccination. To abolish any such regulation is to step back two centuries.—*Boston Medical and Surgical Journal.*

Some of the Characteristics and Work of the Late Professor Brown-Séquard.—"When, in 1852," says the London correspondent of *The Lancet*, "Claude Bernard published in the *Comptes Rendus* the results of his experiments in the section of the cervical sympathetic nerve of the rabbit, Dr. Brown-Séquard followed this up the same year by showing that the effects of the section of the sympathetic nerve were the results of the paralysis of the blood-vessels. It may truly be said that he had the 'fever of work.' Any idea that passed through his active brain was immediately consigned to any scrap of paper—newspaper wrappers, old envelopes, visiting cards—that were at hand. These scraps he would pack in a box, there to lie forgotten. His method of research differed entirely from that of his predecessor, Claude Bernard. The latter would follow obstinately the trail of an idea that had germinated in his mind, and, without swerving from the path, trace it to its logical conclusion; Dr. Brown-Séquard, on the other hand, worked by intuition, his deductions being singularly rapid and apparently savoring of revelation. Once he espoused any cause, scientific or other, he would defend it most obstinately. Thus, on the occasion of the *coup d'état*, his too-openly expressed Republican sentiments drove him to London, where the Hospital for Paralysis was founded expressly for him.

"In the pursuit of physiological knowledge he never spared his own person, and would, without hesitation, expose himself to discomfort and even risks; thus in his experiments on the transfusion of blood into the decapitated head of the criminal, the warm blood injected came from his own veins. In his researches on digestion he swallowed sponge tampons attached to a cord, which tampons he removed saturated with gastric juice. In Mauritius, whither he returned in order to study an epidemic of cholera raging there, he on several occasions deliberately swallowed cholera dejecta.

"When, in 1889, he invented the method of treatment by organic extracts, it was on his own person that the first trials took place. And this leads me to speak of the real value of this much-vaunted and much abused method. I think that the hopes indulged in by the deceased *savant*—that in the injection subcutaneously of orchitic juice there has been found, not only a panacea for senility, but a remedy for locomotor ataxy, neurasthenia, and other disorders of the nervous system—have proved to be illusory. Suggestion plays a leading part in the cases reported. It is, however, only right that I should mention a case of ataxy under the care of Dr. Legroux, where both patient and physician were convinced that a long-continued course of this treatment had worked surprising results. I have seen the patient myself, and he walks well, whereas locomotion used to be almost impossible.

"But the principal debt of gratitude humanity owes to Dr. Brown-Séquard is that he has thus drawn attention to the juice internally secreted and reabsorbed into the circulation by ductless and other glands. Thyroid injections and feeding are a direct outcome of what was regarded as his particular fad, and everyone is acquainted with the marvellous results yielded by this mode of treatment in myxœdema. It is no exaggeration to say that, as far as can be judged, Dr. Brown-Séquard has invented a new system of medicine which has a great future before it. For the past year he had suffered from phlebitis of the right leg, but he was well enough to recently visit the Riviera, and his sudden demise has come as a surprise to his friends. His disappearance from the scientific arena is an irreparable loss, and his death leaves the world distinctly poorer."

Reviews and Notices.

Venereal Memoranda. A Manual for the Student and Practitioner. By P. A. Morrow, A.M., M.D., Clinical Professor of Venereal Diseases in the University of the City of New York; Surgeon to Charity Hospital, etc. New York: William Wood & Co. 1894.

This is the second edition of a very useful little work, especially for students, and the eight years intervening have made a number of changes necessary. In comparing the one with the other, this volume shows the effect of modern bacteriological research in connection with venereal diseases, and especially with gonorrhœa. The etiology of the latter disease has been rewritten and the gonococcus is given full credit. The size and general make up of the work has not been altered.

Aus dem Jahrbuche der Wiener K. K. Krankenanstalten. 1. Jahrgang für das Jahr. Wien und Leipzig: Wilhelm Braumüller. 1892.

An account of the work done in the various departments of the "Rudolfstiftung" hospital for the year.

Transactions of the American Pediatric Society. Fifth session. Bailey & Fairchild. 1893.

This volume of the transactions is edited by Dr. Floyd M. Crandall, and contains a number of interesting papers on infantile diseases.

Tumors, Innocent and Malignant. By J. Bland Sutton, assistant surgeon to the Middlesex Hospital, London. With two hundred and fifty engravings and nine plates. Philadelphia: Lea Brothers & Co. 1893.

In this work, which treats more particularly of the clinical features and appropriate treatment of tumors, without going into the details of operative procedures, the writer has eliminated such growths as have been proven to depend upon micro-organisms. Cancer is retained, and indeed forms a very important feature of the book. By "cancer" he understands a malignant adenoma, "the species being determined by the gland in which the cancer arises." We commend the avoidance in the illustrations of repulsive conditions, from which little is to be learned and which may be made to disfigure a work of this kind. The illustrations are for the most part interesting and instructive, and are not confined to tumor in the human body. The execution in the colored plates is far below the present day standard of excellence. The special index showing the distribution of tumors, according to the various organs in which they develop, serves the purpose of syllabus as well. As a whole, it may be said to be a book worth having.

Catalogue of the Museum, Royal College of Surgeons, Edinburgh. By Charles W. Cathcart. Conservator; Fellow of the College. Volume I.: The skeleton and organs of motion. Edinburgh: James Thin. 1893.

The most important part of this museum's possessions is the "Bell Collection," purchased from Sir Charles Bell in 1825. The object of the catalogue is to make this, together with the general collection, of more practical use to students and physicians. Each number has full descriptions of specimens, etc.

Operative Surgery. By Th. Kocher, M.D., Professor at the University and Director of the Surgical Clinic at the Berne University. With one hundred and sixty-three illustrations. New York: William Wood & Co. 1894.

Exhaustive surgical text-books and systems are numerous, but works to which one can turn in a hurry, before an operation, for brief, explicit information, hints as to technique, points on regional anatomy, and, in fact, just the thing you feel you lack, are indeed rare. Probably no one work ever written gives the operator the desired answer at each interrogation. It is well, then, often to have two books of reference in these practical subjects, provided one has not been too closely copied from the other. The work here presented will respond to most questioning in regard to latest and best methods. It gives evidence, too, of having been made largely from knowledge acquired and tested, and not by a process of extraction from a hash of the writings of other men and other days. Simplicity and conservatism are features throughout, and the instructions deal more with where and how to cut than why and when. No one need hope that in possessing this rather elaborate *vade mecum* he can save himself the trouble of learning surgery, of becoming proficient by clinical experience, or of acquiring skill through practice. He who has reached that point where he can look upon himself as a surgeon, as well as he who is still only an occasional operator, will find in Dr. Kocher's work elements of instructive aid.

Grundriss der Kinderheilkunde. Von Dr. Carl Seitz, Vorstand der Kinderpoliklinik am Reisingerianum und Privatdocent an der Universität München. Berlin: Verlag von S. Karger. 1894.

A work of 478 pages, covering all the medical diseases of childhood, hygiene and diatetics pertaining to this age, including methods of examination, care of the very young in health and disease, abnormalities and deformities. Necessarily many subjects, such as syphilis, and special departments, notably that of dermatology, as well as the eye and ear, have received little attention. These subjects, we believe, are best treated of in special works, and while we would not have them left out entirely, the author has done well in not devoting too much space to their consideration.

Many chapters bear evidence of extensive research, good judgment, and close observation. The treatment is often distinctively German and at times at variance with American therapeutical views. Specialists in children's diseases and German-reading physicians in need of a new work, will do well to add this to their collection.

An Anatomist's Anomaly Blank. Designed for the Use of Dissectors in Recording any Noteworthy Anomaly that may be Found. By A. Hewson, M.D. Philadelphia: P. Blakiston, Son & Co. 1894.

The sheet has proper spaces for the student's name, the principal normal physical characteristics of the subject, and for anomalies of each of the principal organs or classes of tissues, in proper order and sequence. The proper recording of the anatomic peculiarities occurring in the thousands of dissections made in the country would eventually result in interesting and valuable scientific lessons.

Nursing: Its Principles and Practice. For Hospital and Private Use. By Isabel Adams Hampton, Superintendent of Nurses and Principal of the Training-school for Nurses, Johns Hopkins Hospital, etc. Philadelphia: W. B. Saunders. 1893.

This book contains twenty-eight chapters that outline and explain the exact course of study and work in a training-school that fits an educated woman to obtain an honorable and lucrative employment; the duties of a nurse in a hospital and in a private family; methods of procedure in emergency and accident; of bandaging, keeping records, and necessary tests; the care of instruments and appliances; and the use and varieties of the bath. There are excellent definitions, an explanation of common abbreviations in medicine and of the metric system, together with directions for the preparation of solutions. There are numerous illustrations that add to the instructive quality of the text. Miss Hampton speaks from abundant knowledge, and has compiled a valuable text-book for nurses and for those whose duty it is to train nurses. It is convenient in size, and available in price: two dollars. The minutest details concerning the nurse's technique, according to modern methods, are explained in it; and so exhaustive is the description that

no novice can fail to be impressed with the dignity of the profession of nursing. As an exposition of the subject, it is thoroughly practical and available.

Hypnotism, Mesmerism, and the New Witchcraft. By Ernest Hart. New York: D. Appleton & Co. 1893.

Earlier printed in the *Nineteenth Century* and the *British Medical Journal*, the papers in this little book are brought together for readier reference and more available circulation. Written in a clear and familiar style, they are destined to correct many of the popular impressions concerning the possibilities and value of hypnotism. The conclusion is that any remedy which induces further paresis in an already weakened will is one to be carefully avoided. Luys's experiments at the Charité Hospital during a visit by the author are carefully reviewed, and the looseness of this experimenter's methods is amply proved. No doubt hypnotism, its claims, its original presentment, and the sanguine expectations entertained concerning its value, have already had their day. And the "day" of new things, sudden, violent, intense, has been calculated to be about two years and a half.

Notes on the Newer Remedies. By David Cerna, M.D., Ph.D., etc. Pp. 177. Philadelphia: W. B. Saunders. 1893.

This is a serviceable little work, in which the author, as implied in the title, has given the therapeutic applications and conventional modes of administering the remedies more recently brought forward. There is neither evidence nor pretence to originality, the ideal exemplified being that of the ready-reference *vade-mecum*. However, in this field it will fill a useful want.

Alcoholism and its Treatment. By J. E. Usher, M.D., etc. Pp. xi., 151. New York: G. P. Putnam's Sons. 1893.

In this compact little *brochure* the salient points connected with the pathology of inherited and acquired alcoholism are given in a discriminating and lucid manner. The chapters on "Insanity and Alcoholism," "Alcoholic Trauma and Crime," and "Alcohol and its Legal Relations," will be found suggestive; while those on treatment are replete with helpful information.

A tabular statement of the ingredients of the various nostrums recommended from time to time, as afforded by elaborate analysis, adds interest to the exposition.

Access to the information distributed throughout the book is facilitated by a good index.

Syphilis and the Nervous System. A revised reprint of the Lettsomian Lectures for 1890. By W. R. Gowers, M.D., F.R.C.P., etc. Philadelphia: P. Blakiston, Son & Co. 1892.

These lectures, which originally appeared in the medical journals, are well known to readers of periodic literature, so that in their present form they require hardly more than a reiteration of the commendation which they evoked at the time of their delivery.

Dr. Gowers's felicitous powers of statement are well exemplified in these lectures, which are indeed impregnated with a suggestiveness which finds expression in a literary style of true distinction.

Transactions of the American Ophthalmological Society. Twenty-ninth annual meeting. Hartford: Published by the Society. 1893.

Contains numerous interesting papers, several of which are illustrated.

Die Krankheiten der Nase, ihrer Nebenhöhlen und des Nasenrachenraumes. Von Dr. Carl Zarniko. Hals-, Nasen-, und Ohrenaerzt in Hamburg. Mit 132 Abbildungen. Berlin: Verlag von S. Karger. 1894.

The first part deals with propædeutics, and contains some instructive illustrations to facilitate the study of these intricate anatomical regions, and several pictures made from photographs to show the use of specula, etc., while figures of instruments are freely scattered through the text. The text is cut up into paragraphs in the usual German fashion, and besides the sub-headings there are marginal notes, which make reference to any particular subject easy.

The second part treats of special pathology and therapy, and gives the impression of having been prepared by a painstaking and careful observer well up in his specialty. All that is new in this branch appears to be touched upon in one way or another. The book is written for the general practitioner, and one who wishes to get a good knowledge of nose troubles will here find abundant opportunity to first ground himself firmly in the very necessary anatomical requirements to a proper appreciation of diseased conditions and their modes of cure.

Early Human Embryos and the Mode of their Preservation. By Franklin P. Mall, Professor of Anatomy, the Johns Hopkins University.

This is a reprint from the Hospital Bulletin No. 36, urging greater care in the preservation of specimens for embryological study.

Studies from the Department of Pathology of the College of Physicians and Surgeons. Vol. III. 1892–1893.

Contains ten reprints, one being an illustrated report on the recent sanitary inspection of one of the sources of the Croton water-supply.

A Syllabus of Surgery Arranged in Conformity with the American Text-book of Surgery. By N. Senn, M.D., Ph.D., LL.D., Chicago; Professor of the Practice of Surgery and Clinical Surgery in Rush Medical College; Professor of Surgery in the Chicago Polyclinic; Surgeon-in-chief in St. Joseph's Hospital, etc. Philadelphia: W. B. Saunders.

This syllabus of lectures is intended to meet the requirements of the surgical lecturer in the preparation of his daily work, and will surely prove an aid in the presentation of his subjects in a systematic and succinct manner. To the student who feels the bewildering effects of the didactic lecture this little work will come as remembrancer, and will obviate the necessity of note-taking in the class-room. Its especial field of usefulness will of course be found in the class-room recitation, and quiz in connection with the American Text-book.

The Year-Book of Treatment for 1894.

This, which is the tenth of the series, contains the usual amount of extractive matter from current literature (especially that published in the English language), with an addition of a new article upon medical diseases of children by Dawson Williams, and another upon Bacteriology by William Hunter.

Out of the large mass of matter presented, even one who devotes much time to the weekly and monthly journals will find something new, and to him who must rely upon such sources for picked and condensed articles the work must have a decided value. The summary of the therapeutics, dealing as it does chiefly with new remedies, is a good feature of the work. Although one feels that many chapters might with advantage be more edited and less extracted, the purchaser will be repaid in the information he will find upon almost any subject he may chance to look up. We are gratified at the frequent mention of the Record in extracts from its "Editorial" as well as from its "Original Article" departments.

Only Three of the New England States remain as yet without any statutory regulations of the practice of medicine: Rhode Island, Massachusetts, and Maine. The Rhode Island State Medical Society is making a vigorous effort to have a law enacted by the next Legislature providing for regulation of medical practice in that State.

Society Reports.

ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

Held in Rome, Italy, March 29, 30, and 31, and April 1, 2, 3, 4, and 5, 1894.

SECTION ON PRACTICAL MEDICINE.

(Continued from p. 504.)

Treatment of Rheumatic or Hepatic Diabetes.—Dr. Monin, of Paris, recommended the administration of permanganate of potassium, in doses of ten drops of a five per cent. aqueous solution gradually increased to thirty drops twice a day, after each of the principal meals, given in a glass of old wine. As a drink in these cases he prescribed a hot infusion of maté. This medication reinvigorates the vital forces, reduces the thirst, and causes a notable diminution of the amount of sugar in the urine, without the necessity of resorting to a strict anti-diabetic regimen. In cases of diabetes with enlargement of the liver, this treatment brings about a reduction in size of the organ within ten or twenty days, and at the same time an improvement in the symptoms associated with hepatic congestion. Another constant effect of the permanganate is an increase in the number of red blood corpuscles and in their proportion of oxyhemaglobine.

The hot eight per cent. infusion of maté, taken without sugar at meal-time and between meals, in amounts varying, according to circumstances and the thirst of the patient, from two to six quarts a day, adds greatly to the good effects of the permanganate. The maté should be used in powder, and this powder should be taken together with the infusion suspended in it. The richness of ilex paraguayensis in tannin and chlorine combined and the considerable proportion of the soluble salts of potassium and of magnesium which it contains explain in part its useful anti-diabetic action. Maté reduces the amount of sugar excreted in the urine in the same way as does opium, but, unlike the latter drug, produces no narcotism, constipation, or cardiac depression. On the contrary, the reawakening of the psycho-physical forces, the regulation of the action of the bowels, and the tonic action of maté upon the heart are properties which render it of special service in cases of diabetes mellitus.

Dr. Monin, in conclusion, said that he had employed the course of treatment here outlined in upwards of forty cases, and was able to affirm in the most positive terms its great efficacy in the hepatic or arthritic forms of diabetes. The nervous and pancreatic varieties of the disease are less favorably affected, although a palliation of the symptoms in grave forms of these varieties may often be obtained by means of the permanganate and maté.

Acetonic and Ethyldiacetic Intoxications.—Dr. Virgilio Machado, of Lisbon, read a paper with this title, of which the main points were that there is no acetone in normal urine, and that the presence of acetone or of ethyldiacetic ether in the blood gives rise to nervous symptoms very like to those of diabetic coma.
